## 214. Buff-throated Foliage-gleaner

### *Automolus ochrolaemus*

**French:** Anabate à gorge fauve **German:** Fahlkehl-Baumspäher **Spanish:** Ticotico Gorgielaro  
**Other common names:** Buff-throated Leaf-gleaner/Automolus

**Taxonomy.** *Anabates ochrolaemus* Tschudi, 1844, Peru.

Vocal differences described for race *exsertus* and perhaps others suggest that more than one species may be involved; *pallidigularis* considered a separate species by some authors. Populations from Belize may show signs of intergradation between *cervinigularis* and *hypophaeus*; proposed race *amusos* described (from Honduras) as paler than latter, but considered not diagnosable. Some signs of introgression between *auricularis* and nominate in W Brazil. Seven subspecies recognized.

#### Subspecies and Distribution.

*A. o. cervinigularis* (P. L. Slater, 1857) - Caribbean lowlands of S Mexico (Veracruz and S from S Quintana Roo), Guatemala and W Belize.  
*A. o. hypophaeus* Ridgway, 1909 - Honduras S to NW Panama.  
*A. o. exsertus* Bangs, 1901 - Pacific slope of SW Costa Rica and W Panama.  
*A. o. pallidigularis* Lawrence, 1862 - E Panama, N & W Colombia (E to Magdalena Valley in N) and NW Ecuador (S to W Guayas and Los Rios).  
*A. o. turdinus* (Pelzelin, 1859) - SE Colombia (S from W Meta and Vaupés), S Venezuela (Amazonas, Bolívar) and the Guianas S to E Ecuador, NE Peru and N Brazil (N of R Amazon).  
*A. o. ochrolaemus* (Tschudi, 1844) - S of R Amazon, from E Peru and W Brazil (E to left bank of R Purús) S to C Bolivia (W Pando S to NW Santa Cruz).  
*A. o. auricularis* J. T. Zimmer, 1935 - C Brazil (from right bank of R Purús E to E Pará) S to NE Bolivia (E Pando, NE Santa Cruz).

**Descriptive notes.** 18-19 cm; 30-46 g. Fairly large, rather plain foliage-gleaner. Nominate race dark brownish face with faint flammulations on auriculars, bold buff eyering; crown and nape dark brown with faint blackish-brown scalloping; back and rump rich dark brown, blending to dark chestnut uppertail-coverts; wing-coverts rich dark brown, remiges slightly paler, more rufescent; tail rounded, rectrices with tips mostly rounded, dark chestnut; throat deep buff, malar area slightly more ochraceous and with faint dark flecks; breast with vague streaking medium brown and ochraceous buff, fading posteriorly; belly brown, flanks darker,

more rufescent brown, undertail-coverts dull chestnut; iris brown to dark brown; upper mandible blackish-horn to grey to horn-brown, lower mandible horn to greenish-buff to grey; tarsus and toes olive, greenish-brown or greenish-grey. Sexes alike. Juvenile is slightly duller, with eyering less distinct, crown tinged chestnut, face tinged rufous, throat and breast slightly mottled. Race *auricularis* is larger and duller than nominate, back more greyish-olive, underparts paler, dark feather margins in centre of breast much reduced; *turdinus* has paler throat (almost whitish centre of chin), slightly less ochraceous underparts, differs from previous in darker underparts with more markings, brighter undertail-coverts; *pallidigularis* is the most distinctive, palest and duller, with nearly white throat, dull brown underparts no trace of ochraceous tinge; *hypophaeus* is very similar to distant *turdinus*, differs primarily in darker ochraceous throat, paler breast, brighter rufous undertail-coverts; *exsertus* is like last but duller, less ochraceous and more uniform below; *cervinigularis* is darkest and most richly coloured, with crown blackish, throat brighter, deeper ochraceous. Voice. Song in South America a descending series of nasal notes, "kee-kee-kr-kr", "jee, jee, ju-ju-ja" or "ki, ki, ke-ke-kukukrrr"; in Costa Rica, a loud, harsh rattle lasting 2-5 seconds, repeated 10-30 times per minute (Pacific *exsertus*), but in Caribbean lowlands (*pallidigularis*) described as sharper, higher and faster, decelerating and fading at end, with unusual nasal quality; in Mexico (*cervinigularis*), as descending rattle 1-1.5 seconds long, repeated frequently. Call of *pallidigularis* described as nasal "rack", of *cervinigularis* as low gruff "chuk", sharp nasal "pe-duk" and hard "tchehr"; alarm call is loud descending rattle.

**Habitat.** Tropical lowland evergreen forest, tall second growth and coffee plantations in Middle America; in Amazonia, primarily transitional and seasonally flooded forest and swamp-forest, or in large, old treefall gaps in *terra firme*; also in lower montane forest in Guyana (*turdinus*); primarily in second growth in W Ecuador (*pallidigularis*). Mostly from near sea-level to 1000 m; locally to 1400 m in Andes and to 1650 m in Middle America.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera, spiders, and Heteroptera; Dermaptera, ants, small frogs and small lizards (*Anolis limifrons*) also recorded. Forages singly or in pairs, often or usually in mixed-species flocks; from understorey, usually dense, to lower mid-storey, occasionally on ground. Hops and clambers along branches. Acrobatically gleans and pulls arthropods and small vertebrates from dead leaves, epiphytes (including bromeliads) and debris. Dead-leaf specialist; at one site in SE Peru, 94% of observed foraging manoeuvres were directed at dead leaves. In Middle America also feeds occasionally on ground, by flaking leaf litter.

**Breeding.** Season Feb-May in Costa Rica, eggs Mar-May. Monogamous. Nest a broad, shallow cup of a single type of plant fibre (usually rachides of compound leaves) placed in expanded chamber at end of horizontal tunnel c. 40-75 cm long, excavated in dirt bank; estimated territory size 11 ha in transitional forest in SE Peru. Clutch 2-3 eggs; incubation shared by both sexes, period 20-21 days; chicks fed by both members of pair, nestling period c. 18 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to fairly common in most of its range. Density estimated to be 3-4 birds/km<sup>2</sup> at two sites in French Guiana. Present in fragmented forests.

## 215. Olive-backed Foliage-gleaner

### *Automolus infuscatus*

**French:** Anabate olivâtre **German:** Olivrücken-Baumspäher **Spanish:** Ticotico Oliváceo  
**Other common names:** Para Foliage-gleaner (*paraensis*)

**Taxonomy.** *Anabates infuscatus* P. L. Slater, 1856, eastern Peru.

Forms a superspecies with *A. leucophthalmus*, as suggested by voice, plumage pattern and biogeography. Recent study shows that race *paraensis* is vocally distinct, and should be treated as a separate species. Races S of R Amazon significantly larger in measurements than those N of it, but none is diagnosable by biometrics alone. Five subspecies currently recognized.

#### Subspecies and Distribution.

*A. i. infuscatus* (P. L. Slater, 1856) - SE Colombia (S from S Meta and E Guainia), E Ecuador, E Peru and N Bolivia (W Pando, extreme N La Paz).  
*A. i. badius* J. T. Zimmer, 1935 - E Colombia (Vichada), S Venezuela (W Bolívar, Amazonas) and NW Brazil (E, N of R Amazon, to lower R Negro).  
*A. i. cervicalis* (P. L. Slater, 1889) - E Venezuela (E Bolívar), the Guianas and N Brazil (lower R Negro E to Amapá).  
*A. i. purusianus* Todd, 1948 - W Brazil S of Amazon (E to, presumably, left bank of R Madeira).  
*A. i. paraensis* Hartert, 1902 - NC Brazil (from right bank of R Madeira E to Maranhão, S to Rondônia and N Mato Grosso).

**Descriptive notes.** 18-19 cm; 28-42 g. Rather plain, dark foliage-gleaner with striking white throat. Nominate race has blackish-brown face, inconspicuous dull buff flammulations on auriculars, lores grizzled blackish-brown and buff; forehead blackish-brown with inconspicuous broad rufescent brown shaft streaks, blending to dark brown crown with faint streaks, faint blackish scalloping on hind-crown; vague collar dark brown with faint light brown shaft streaks; back and rump rich dark olivaceous brown, blending to dark reddish-brown uppertail-coverts; wing-coverts rich dark brown, slightly darker primary coverts,

slightly paler remiges tinged rufescent, dull buff bend of wing; tail slightly rounded, rectrices with tips mostly rounded, dark reddish-chestnut; throat, malar area and side of neck white, blending to whitish centre of breast faintly washed grey, becoming buffy posteriorly and blending to light buff-brownish buff; side of breast broadly dark olive-brown, blending to more rufescent brown flanks; undertail-coverts light brown; iris dark brown to light brown or hazel; upper mandible black to dark olive-horn, lower mandible olive-horn to grey to pale brown; tarsus and toes greyish-green to yellowish-olive. Differs from similar *A. leucophthalmus* in less rufescent coloration throughout, shorter bill on average, dark eyes. Sexes alike. Juvenile is slightly darker and duller, crown feathers shorter. Race *paraensis* is like nominate but crown duller, slightly more greyish, with broader dark margins producing more scalloped look, tail darker rufous than others; *purusianus* differs from previous in having more rufescent, less olivaceous, underparts, especially forehead (thus approaching nominate in rufescent coloration); *cervicalis* has crown and hindneck more rufescent and with reduced dark edging, thus contrasting more with back, also flanks slightly more brownish; *badius* has lower breast and belly greyer than other races, differs from previous in having richer, redder brown back (reddest of any race), darker crown, duller underwing-coverts. Voice. Song a loud, fast, staccato, slightly descending rattle, "tchi-r-r-r-r-r-r-r-r-r-r-r-r-r-r", c. 2-3 seconds long (c. 1 second in *badius* and *cervicalis*), c. 18-22 notes per second; *paraensis* song differs from all others in being much slower, of 4-10 notes, the first different and longer than rest, "jueet-reet-reet-reet", with quality of grating laugh, lasts 1-1.5 seconds. Contact/alarm call a sharp "chik-uh" or "chik-wuk", first note higher-pitched than second, sometimes just single "chik"; analogous call of *badius* and *cervicalis* slower and differing in tone, more *Synallaxis*-like, "chik-gwaah"; in contrast, that of *paraensis* a single, liquid "quip" or "queep".

**Habitat.** Tropical lowland evergreen forest, mainly *terra firme* and transitional forest, locally in *várzea* and in second-growth forest; from near sea-level to 700 m.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera, spiders; Heteroptera, Lepidoptera larvae and pupae, and small lizards also recorded. Forages singly or in pairs, usually in mixed-species flocks, in undergrowth, occasionally to mid-storey, rarely to subcanopy. Acrobatically gleans and pulls arthropods from dead leaves, debris, and occasionally bark crevices and epiphytes. Dead-leaf specialist; in SE Peru, 88% of observed foraging manoeuvres at one site and 71% at another were directed at dead leaves.

**Breeding.** Active nest in Mar in French Guiana; fledgling in Dec in C Brazil. Presumably monogamous. Nest a broad, shallow cup of plant fibres, often rachides of compound leaves, placed at end of tunnel 2 m long excavated in dirt bank; estimated territory size 12 ha in transitional forest in SE Peru. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common to fairly common in most of its range. Density estimated at 3-12 birds/km<sup>2</sup> in transitional forest in SE Peru and 9-21/km<sup>2</sup> at four *terra firme* sites in French Guiana; densities probably higher in *terra firme* forest in W Amazonia. Occurs in numerous protected areas, e.g. Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, and Cristalino State Park, in Brazil. Persists in relatively small forest fragments.

**Bibliography.** Borges & Stouffer (1999), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Gyldenstolpe (1951), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Koepeke (1972), Munn (1985), Novaes (1961a, 1990), Oniki & Willis (1983a), Oren (1990), Parker & Bailey (1991), Parker & Remsen (1987), Parker, Castillo *et al.* (1991), Parker, Foster *et al.* (1993), Parker, Parker & Plenge (1982), Pinto (1953, 1978), Remsen (2003a), Remsen & Parker (1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1995, 1997), Robinson *et al.* (1990), Rodner *et al.* (2000), Rosenberg (1997), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Sick (1993, 1997), Sneath (1935), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1986, 1988a, 1988b, 1994), Todd (1948b), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer, J.T. (1930, 1935a), Zimmer, K.J. (2002).

## 216. White-eyed Foliage-gleaner

### *Automolus leucophthalmus*

**French:** Anabate aux yeux blancs

**Spanish:** Ticotico Ojiblanco

**German:** Weißaugen-Baumspäher

**Taxonomy.** *Anabates leucophthalmus* Wied, 1821, Rio Cachoeira, Bahia, Brazil.

Forms a superspecies with *A. infuscatus*, as suggested by voice, plumage pattern and biogeography. Race *lammi* more similar vocally to race *paraensis* of that species than to other races of present species. Race *sulphurascens* varies clinally, with populations in more humid areas darker and those in drier interior paler. Proposed race *bangsi*, from Bahia (Brazil), regarded as a synonym of nominate, following initial confusion over type locality of latter. Three subspecies recognized.

#### Subspecies and Distribution.

*A. l. lammi* J. T. Zimmer, 1947 - E Brazil (Paraíba, Pernambuco).

*A. l. leucophthalmus* (Wied, 1821) - E Brazil (E Bahia).

*A. l. sulphurascens* (M. H. K. Lichtenstein, 1823) - SC & SE Brazil (E Mato Grosso, S Goiás and S Bahia S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** 19-20 cm; 25-35 g. Rather plain, dark rufescent foliage-gleaner with striking white throat. Nominative race has dark brownish face, faint rufescent shaft streaks on auriculars, lores grizzled reddish-brown and buffy; crown dark reddish-brown with narrow rufous shaft streaks; back and rump dark reddish-brown, blending to bright rufous upper-tail-coverts; wings dark rufous, pale cinnamon bend of wing; tail slightly rounded, rectrices mostly rounded with slight points, bright rufous; throat, malar area and side of neck white, blending to whitish centre of upper breast, becoming bright buffy posteriorly and to belly;

broad area on side of breast and flanks conspicuously ochraceous tawny; undertail-coverts light rufous; iris whitish; upper mandible brownish to black, lower mandible greenish-grey to light grey; tarsus and toes greyish. Differs from similar *A. infuscatus* in more rufescent coloration throughout, longer bill on average, white eyes. Sexes alike. Juvenile has more uniform crown and back, shorter crown feathers, darker brown sides and flanks, slightly darker breast and belly. Race *lammi* is like nominate, but upperparts darker and browner, less rufescent, throat tinged pale yellow and more sharply demarcated from breast, breast more creamy olive-buff, sides browner, less rufescent, flanks and undertail-coverts less tawny, bill darker, wing longer (some overlap); *sulphurascens* has back, rump and tail paler, flanks less extensively reddish-brown, belly less brownish (plumage becoming darker in more humid areas, paler in drier interior of range). Voice. Song a loud, vigorous, fast series of c. 5 squeaky, syncopated "ki-dee" or "tu-wút" notes; call "téh-koeé". Race *lammi* song slower and more grating, call more liquid, voice more like that of race *paraensis* of *A. infuscatus*. **Habitat.** Tropical lowland evergreen forest, also tall second growth; from near sea-level to 1000 m, locally to c. 1400 m.

**Food and Feeding.** Recorded food items are Coleoptera (including families Erotylidae, Melolonthidae, Chrysomelidae), Orthoptera (Tettigoniidae, Locustidae), Hemiptera, Dermaptera, and Diptera pupae; on one occasion photographed carrying a snail in bill. Usually observed in mixed-species flocks, especially those with Lesser Woodcreeper (*Xiphorhynchus fuscus*) and Red-crowned Ant-tanager (*Habia rubica*); mainly in understorey, occasionally to mid-storey. Gleans and pulls arthropods from dead leaves and debris, mainly in dense undergrowth.

**Breeding.** Season presumably during austral spring-summer; eggs in Oct and Jan in Brazil. Presumably monogamous. Nest a broad, shallow cup c. 8 cm in diameter made of dry plant stems, often rachides of compound leaves, also some hair, placed at end of horizontal tunnel c. 60 cm long excavated in dirt bank, nest-chamber c. 20 cm in diameter. Clutch 3-4 eggs.

#### Movements.

Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common. In Brazil, common in Augusto Ruschi Biological Reserve and Itatiaia and Iguaçu National Parks; fairly common in Sooretama Biological Reserve and Serra dos Órgãos National Park, uncommon in Tijuca and Serra da Canastra National Park, and rare in Poço das Antas Biological Reserve. In Paraguay, common in Caaguazú and Ybicuí National Parks, uncommon in Cerro Corá National Park, and present in San Rafael National Park. Fairly common in Iguazú National Park, in Argentina. Extensive deforestation within its range has dramatically reduced area of habitat available to this species, but it persists in small and degraded forest fragments. Race *lammi* almost certainly merits conservation status of threatened; it occurs in perhaps only two areas with official protection, i.e. Mucici Ecological Reserve and Pedra Talhada State Park. Nominative race, known from few localities in Bahia, likewise deserves threatened status.

**Bibliography.** Aleixo (1997), dos Anjos *et al.* (1997), Anon. (2003d), Belton (1984), Brooks *et al.* (1993), Cândido (2000), Caneyari *et al.* (1991), Cory & Hellmayr (1925), Euler (1900), Ferreira de Vasconcelos & Melo-Júnior (2001), Hayes (1995), Hayes & Scharf (1995a, 1995b), Kratter & Parker (1997), Madroño, Robbins & Zyskowski (1997), Marini, Moita-Júnior *et al.* (1997), Mazar Barnett & Pearman (2001), Melo-Júnior *et al.* (2001), Narosky *et al.* (1983), Novaes (1961a), Olog (1963a), Parker & Goerck (1997), de la Peña (1988), Pinto (1978), Piratelli *et al.* (2000), Ridgely & Tudor (1994), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1993, 1997), Silveira (1998), Stotz *et al.* (1996), Terborgh *et al.* (1990), Zimmer, J.T. (1947), Zimmer, K.J. (2002).

## 217. Brown-rumped Foliage-gleaner

### *Automolus melanopezus*

**French:** Anabate brunâtre

**German:** Orangekehl-Baumspäher

**Spanish:** Ticotico Pardo

**Taxonomy.** *Anabates melanopezus* P. L. Slater, 1858, Rio Napo, Ecuador.

No obvious sister-species in genus. Although the N and S populations are evidently separated geographically, no appreciable phenotypic difference between them is evident. Monotypic.

**Distribution.** SE Colombia (W Putumayo), E Ecuador and N Peru (Amazonas, N Loreto); separate population in SE Peru (S Ucayali, Cuzco, Madre de Dios), W Brazil (SW Amazonas, Acre, N Rondônia) and N Bolivia (W Pando).

**Descriptive notes.** 16-18 cm; 27-32 g. A rather plain, smallish *Automolus*. Has face mostly rich dark brown, hint of paler shaft streaks on auriculars, lores grizzled brownish and greyish; crown rich brown, some faint paler shaft spotting on forehead; back and rump rich brown, blending to chestnut-tinged uppertail-coverts; wing-coverts dark reddish-brown, remiges slightly more rufescent, dull ochraceous bend of wing; tail slightly rounded, rectrices with tips almost rounded, dull reddish-brown; throat dull tawny-buff, blending to more ochraceous malar area and light brown breast and belly; sides and flanks broadly

darker brown, tinged rufescent on lower flanks, undertail-coverts pale rufescent brown; iris dark red to orange (source of variation uncertain); upper mandible dark greyish to blackish, sometimes pale tip, lower mandible pale grey to greyish-brown; tarsus and toes olive-grey to greenish-grey. Sexes alike. Juvenile has darker, browner underparts, narrow dark margins on feathers of crown, breast and belly, paler throat, brown iris. Voice. Song a fast, rhythmic "whip, whip, whudididit-wrrrrrr", or staccato burst of upward-inflected notes, "whe-de-de-de-de-de", slightly descending at end; lasts c. 1-1.5 seconds.

**Habitat.** Tropical evergreen forest, mainly floodplain-forest, primarily in or in vicinity of *Guadua* bamboo thickets; mostly 300-500 m, locally to 600 m.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera, Heteroptera, and spiders; small tree-frogs also recorded. Regularly observed in mixed-species flocks, foraging in dense undergrowth to lower mid-storey. Acrobatically gleans and pulls arthropods from dead leaves and debris. At one site in SE Peru, c. 45% of observed foraging attempts were in bamboo, directed primarily at dead leaves; more than 90% of all foraging involved searching of dead leaves.

**Breeding.** No information.

#### Movements.

Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon in all parts of range. Occurs in Manu National Park and Biosphere Reserve.

**Bibliography.** Angehr & Aucca (1997), Cory & Hellmayr (1925), Foster *et al.* (1994), Hilty & Brown (1986), Kratter & Parker (1997), Parker (1982), Parker & Remsen (1987), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1983, 1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson *et al.* (1990), Rosenberg (1997), Sick (1993, 1997), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Todd (1948b).

## 218. White-throated Foliage-gleaner

### *Automolus roraimae*

**French:** Anabate à gorge blanche **German:** Tepuibaumspäher **Spanish:** Ticotico Gorgiblanco  
**Other common names:** Tepui Foliage-gleaner; Neblina Foliage-gleaner ("*Philydor hylobius*")

**Taxonomy.** *Automolus roraimae* Hellmayr, 1917, Mt Roraima, Bolívar, Venezuela.

Species was originally described in the genus *Philydor*, as *P. albigularis*, but that name preoccupied. Suspected by some authors to be possibly better returned to that genus, whereas others consider that it is most closely related to *A. ochrolaemus* or even to *Syndactyla ruficollis*; further research needed. Named form *Philydor hylobius*, previously believed by some to be an isolated population of *P. atricapillus*, is invalid; represents the juvenile plumage of present species. Sight records from W Guyana presumed to pertain to nominate race. Four subspecies recognized.

#### Subspecies and Distribution.

*A. r. paraquensis* Phelps, Sr. & Phelps, Jr., 1947 - Cerro Paraque, in SC Venezuela (NW Amazonas).

*A. r. duidae* Chapman, 1939 - SC Venezuela (Cerro Duida, Neblina, Huachamacari and Yavi, and Serranía Parí, in Amazonas) and extreme N Brazil in Amazonas (Cerro Neblina) and Roraima (Serra Parima).

*A. r. urutani* Phelps, Jr. & Dickerman, 1980 - Cerros Urutani, Jaua and Sarisariñama, in SE Venezuela (S Bolívar).

*A. r. roraimae* Hellmayr, 1917 - SE Venezuela (SE Bolívar on Mt Roraima, tepuis of Gran Sabana area), W Guyana (Potaro Plateau, Mt Roraima) and extreme N Brazil (Mt Roraima).

**Descriptive notes.** 18 cm; 22-32 g. Smallest *Automolus* and with the most striking face pattern. Nominative race has conspicuous white supercilium, rest of face blackish-brown; crown dark greyish-brown, back rich dark rufescent brown, rump and uppertail-coverts chestnut-rufous; wing-coverts mostly rich dark rufescent brown, darker brown primary coverts, slightly more rufescent remiges; tail slightly rounded, chestnut-rufous; throat and malar area white; breast and belly medium brown, flanks and undertail-coverts darker brown; iris brown to dark brown; upper mandible black, lower mandible pinkish-grey to

silver to black with pinkish-coloured base; tarsus and toes olive-yellow to greenish-grey. Sexes alike. Juvenile has supercilium ochraceous, underparts more rufous, dusky-tipped feathers on breast and belly. Race *paraquensis* differs from nominate in having paler and more yellowish-brown (less rufous) back, paler and more greyish-olive breast and belly; *duidae* is described as like nominate but with more rufescent crown and underparts, much brighter belly; *urutani* is generally paler, less rufous above and less ochraceous below, than previous, with paler flanks and undertail-coverts. Voice. Song a long accelerating series of very harsh guttural "jiza" notes, rising in pitch, usually preceded by a few single short notes; call a short, harsh "chek" or "tzik".

**Habitat.** Montane evergreen forest, ranging into stunted woodland; mostly 1100-2475 m.

**Food and Feeding.** Recorded dietary items include Coleoptera and Orthoptera. Forages singly, in pairs or in small family parties, often in mixed-species flocks; mostly in understorey, occasionally to mid-storey. Generally moves around low in undergrowth, less often clammers in vine tangles;

sometimes hitches along limbs and even up vertical trunks (unlike others of genus). Gleans and probes for arthropods; peers at dead leaves, live leaves, branches and moss; occasionally hangs upside-down.

**Breeding.** In Guyana, in Mar-Apr, gonad condition indicated recent breeding. No further information. **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tepuis EBA. Uncommon to locally common. Present in Canaima National Park, in Venezuela.

**Bibliography.** Anon. (2003d), Barnett *et al.* (2002), Braun *et al.* (2003), Chapman (1931, 1939), Cory & Hellmayr (1925), Dickerman *et al.* (1986), Hilty (2003a), Lentino *et al.* (1998), Mayr (1971), Mayr & Phelps (1967, 1971), Phelps, W.H. & Phelps (1947), Phelps, W.H. Jr. & Dickerman (1980), Pinto (1978), Renjifo *et al.* (1997), Ridgely & Tudor (1994), Rodner *et al.* (2000), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore & Phelps (1956), Willard *et al.* (1991).

219. Ruddy Foliage-gleaner

*Automolus rubiginosus*

**French:** Anabate rubiginoux    **German:** Zimtkehl-Baumspäher    **Spanish:** Ticotico Castaño  
**Other common names:** Ruddy Leaf-gleaner

**Taxonomy.** *Anabates rubiginosus* P. L. Selater, 1857, Córdoba, Veracruz, southern Mexico. No obvious sister-species in genus. Vocal and substantial morphological differences between Guianan Shield race *obscurus* and other races suggest that at least two species are involved; vocalizations of many of the distinctive races are unknown. Black-tailed races *nigricauda* and *saturatus* formerly considered to represent a separate species. Proposed race *umbrinus*, described (from Guatemala) as like nominate but paler and redder above and paler below, considered to be not reliably distinguishable from *veraepacis* and synonymized with it by most authors; in addition, that broader taxon thought by some to be possibly indistinguishable from nominate. Supposed characters of proposed race *moderatus*, described from single specimen from N Peru, evidently represent individual variation within highly variable *watkinsi*. Proposed species *A. xanthippe* (W Panama) considered a synonym of *fumosus*. Racial identity of birds in SW Venezuela (Apure) uncertain; tentatively assigned to *cinnamomeigula*. Recent specimens from Amazonian NE Peru (away from Andes) are small, and dark below, much like geographically distant *obscurus*; believed possibly to represent an undescribed taxon. Fourteen subspecies currently recognized.

**Subspecies and Distribution.**

- A. r. guerrensis* Salvin & Godman, 1891 - SW Mexico (Guerrero, W Oaxaca).
- A. r. rubiginosus* (P. L. Selater, 1857) - mountains of E Mexico (Veracruz).
- A. r. veraepacis* Salvin & Godman, 1891 - mountains from S Mexico (E Oaxaca, Chiapas) and Guatemala E to N Nicaragua.
- A. r. fumosus* Salvin & Godman, 1891 - mountains of extreme SW Costa Rica and W Panama (Chiriqui, San Blas).
- A. r. saturatus* Chapman, 1915 - highlands of extreme E Panama (Darién) and NW Colombia (Antioquia).
- A. r. rufipictus* Bangs, 1898 - Santa Marta Mts, in N Colombia.
- A. r. nigricauda* Hartert, 1898 - W Colombia (Baudó Mts, and foothills of W Andes) S to W Ecuador (S to El Oro) and narrowly to N Peru (Tumbes).
- A. r. sasaimae* Meyer de Schauensee, 1947 - E Andes of Colombia (W slope in Boyacá and Cundinamarca).
- A. r. cinnamomeigula* Hellmayr, 1905 - SW Venezuela (Apure) and foothills of E Colombian Andes (Meta).
- A. r. caquetae* Meyer de Schauensee, 1947 - foothills of E Andes in S Colombia (Nariño, Caquetá, Putumayo) and NE Ecuador (Sucumbios).
- A. r. brunnescens* Berlioz, 1927 - foothills from E Ecuador (S from Napo) S to NE Peru (Amazonas).
- A. r. watkinsi* Hellmayr, 1912 - Andean foothills from N Peru (San Martín) S to N Bolivia (La Paz), also extreme SW Brazil (Acre).
- A. r. venezuelanus* J. T. Zimmer & Phelps, Sr., 1947 - tepui region of S Venezuela (Bolívar, Amazonas).
- A. r. obscurus* (Pelzelin, 1859) - the Guianas and NE Brazil.

Also Amazonian NE Peru (away from Andes), where identity uncertain; possibly an undescribed taxon.

**Descriptive notes.** 17-20 cm; 43-52 g. *obscurus* 23-35 g. The darkest *Automolus*. Nominate race has dark reddish-brown face, faint paler flammulations on auriculars, lores duller, slightly paler; crown very dark brown with reddish tone, slightly darker feather margins producing faint scalloping; back dark reddish-brown, slightly paler than crown, rump dark brown, slightly paler than back; uppertail-coverts with dark reddish-brown tips; wings dark reddish-brown; tail slightly rounded, rectrices with somewhat rounded tips, dark reddish-brown; throat dark rufous, feathers tipped rufescent brown, blending to reddish-

brown breast with vague paler shaft spotting; belly rufescent brown, sides and flanks darker, undertail-coverts reddish-brown; iris dark brown to greyish-brown; upper mandible black to grey, lower mandible pinkish-grey to dusky horn, sometimes paler base or darker tip; tarsus and toes brown to greyish-olive. Sexes alike. Juvenile has paler, ochraceous throat and breast, breast with hint of scaling or streaking. Race *guerrensis* is much paler than nominate, upperparts and face medium brown, tail much paler (dark rufous), reddish below restricted to upper breast, rest of underparts paler; *veraepacis* is described as slightly paler generally than nominate; *fumosus* is like previous, but crown and back much darker, less tawny, wings darker, almost same colour as back, throat paler and more ochraceous, breast and belly olive-brown with only trace of rufescent tinge; *saturatus* is darker than other Middle American races, compared with nominate has crown and back slightly darker (less reddish), rump and uppertail-coverts much darker (same colour as back), wings much darker (less rufescent), tail slaty fuscous brownish, almost black, throat paler and more contrasting, lower breast and belly olive-brown, flanks and undertail-coverts dark brown, also juvenile throat distinctly paler than adult; *nigricauda* has blackish tail like last, but differs in being generally paler, with back paler than crown, flanks paler; *sasaimae* is described as like previous, but tail rufous, throat and upper breast rufous (not dark chestnut), lower breast and belly much paler, back tinged olivaceous, wing-coverts and primary edges rufous (not brown); *rufipictus* is much paler than last, has back medium brown, tail dark chestnut; *cinnamomeigula* is similar to previous, but auriculars dark olive (not rufous), underparts solid cinnamon-rufous except for buff-

rufous centre of belly; *watkinsi* is like last, but crown dark reddish-chestnut, chin and upper throat ochraceous, conspicuously paler than lower throat and malar area, belly medium olive-brown, flanks lacking rufescent tinge, but exceptional individual or local variation; *brunnescens* is uniform dark rufescent brown above, with throat and upper breast dark rufous, rest of underparts rufescent brown; *caquetae* differs from previous in having paler upperparts, chestnut of throat and breast paler (and less extensive on breast), belly and flanks much less rufescent; *obscurus* is substantially smaller than others, with smaller bill and feet, fairly dark, has throat and breast perhaps the reddest and darkest of any South American race, belly rufescent olive-brown; *venezuelanus* is like last, but crown, back and wings less rufescent, more olivaceous, and belly paler. **VOICE.** Call (possibly song) in Mexico a 2-noted, nasal "yeh-énk, yeh-énk", repeated 2-3 times; also gives dry chatter and slowly repeated "chack". Call in SW Costa Rica and W Panama (*fumosus*) described as whistled "ka-kweek" or nasal "ta-whoip" or "ka-whick", also nasal, whining "nyeeeah" or "knaaayr, kaayr", and nasal chatter. W of Andes and in W Amazonia a distinctive, clear, querulous "tcha-tcheah" or "kweeeeahhh", often repeated at short intervals. In Guianan Shield region a sharp, emphatic "chuck-kwihhh", second note rising.

**Habitat.** Montane and tropical lowland evergreen forest; primarily hilly and lower montane tropical forest in Middle America and Andean region; mainly lowland tropical forest in the Guianas and NE Brazil (*obscurus*). Some indication of a preference for bottoms of densely vegetated ravines. At 500-2500 m in Middle America; from near sea-level to 1300 m in South America.

**Food and Feeding.** Recorded dietary items are Orthoptera (including Tettigoniidae), cockroaches (Blattodea), Coleoptera, spiders, also small frogs and lizards. Usually in pairs, rarely in mixed-species flocks, mainly in undergrowth. Gleans arthropods and small vertebrates from dead leaves, and pecks at decaying branches; occasionally flakes leaf litter on ground.

**Breeding.** Eggs in May in S Mexico and Jun in Ecuador; nestlings in Oct in French Guiana. Monogamous, paired throughout year. Two nests described, a broad, shallow platform 15 cm in diameter, made of rootlets, fungal rhizomorphs and soft, fine plant fibres, placed in enlarged chamber 15 cm long and 10 cm high at end of tunnel 0.5-2 m long, excavated in dirt bank. Clutch 2 eggs.

**Movements.** Resident; suggestion of partial altitudinal migration in Mexico.

**Status and Conservation.** Not globally threatened. Rare to locally fairly common. Patchy and local in much of its range; reasons for this not understood, possibly related to details of habitat requirements. Estimated density 3-6 birds/km² at four sites in French Guiana (race *obscurus*). Occurs in several protected areas, e.g. Raleigh Falls-Voltzberg National Park, in Surinam, Rio Palenque Science Centre, in Ecuador, and Tumbes National Reserve and Manu National Park and Biosphere Reserve, in Peru.

**Bibliography.** Alonso *et al.* (2001), Angehr & Auca (1997), Anon. (1998a), Binford (1989), Bond (1945), Cadena, Álvarez *et al.* (2000), Cook (1996), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Foster *et al.* (1994), Gómez de Silva *et al.* (1999), Haverschmidt & Mees (1994), Hilty (1997, 2003a), Hilty & Brown (1983, 1986), Howell & Webb (1995a), Komar (2002), Marin & Carrión (1991), Marshall (1943), Meyer de Schauensee (1947, 1952), Monroe (1968), Novaes (1978), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Rodner *et al.* (2000), Rowley (1966), Salaman, Donegan & Cuervo (2002), Schulenberg (2002), Schulenberg *et al.* (2001), Sick (1993, 1997), Snyder (1966), Stiles (1985), Stiles & Skutch (1989), Stiles *et al.* (1999), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay (1986, 1994), Thurber *et al.* (1987), Todd & Carriker (1922a), Tostain *et al.* (1992), Wetmore (1972), Zimmer (1935a), Zimmer & Phelps (1947).

220. Chestnut-crowned Foliage-gleaner

*Automolus rufipileatus*

**French:** Anabate à couronne rousse    **Spanish:** Ticotico Coronicaño  
**German:** Rostkappen-Baumspäher

**Taxonomy.** *Anabates rufipileatus* Pelzelin, 1859, Pará, Brazil.

No obvious sister-species in genus. Proposed race *maynanus*, from S Peru and Bolivia, described as brighter ochraceous below than nominate, but individual variation prevents diagnosis. Two subspecies recognized.

**Subspecies and Distribution.**

- A. r. consobrinus* (P. L. Selater, 1870) - N & W Amazonia in E Colombia (along base of E Andes S from Arauca, in lowlands S from Meta), S Venezuela (W Barinas S along base of Andes, also NW Bolívar, Amazonas) and the Guianas S to E Ecuador, E Peru, W & NC Brazil (E to R Jurua) and NW Bolivia (S to Cochabamba).
- A. r. rufipileatus* (Pelzelin, 1859) - Brazil S of R Amazon (R Purús E to NW Maranhão).

**Descriptive notes.** 18-19 cm; 31-38 g. A rather uniformly rufescent *Automolus*. Has face mostly rufescent brown, trace of pale shaft streaks on auriculars; crown rather dark reddish-chestnut, blending to darkish warm olivaceous brown back; rump reddish-brown, uppertail-coverts reddish-chestnut; wings mostly darkish rufescent brown, primary coverts slightly darker, bend of wing ochraceous rufous; tail slightly rounded, rectrices with nearly rounded tips (hint of points), rather dark, dull chestnut; throat bright buff, blending to pale dull buff-brown breast and belly; sides and flanks medium dull brown, undertail-coverts

dull rufescent brown; iris yellow-orange to orange (described as brown in Surinam); upper mandible blackish to dusky brown to olive-grey, lower mandible paler, silvery horn to greyish-olive; tarsus and toes greenish-grey to yellowish-olive. Sexes alike. Juvenile has slightly duller and darker upperparts, dusky feather margins on breast, central belly and, occasionally, throat. Race *consobrinus* has more rufescent back, darker, more ochraceous underparts. **VOICE.** Song a series of low, short, fast, staccato, almost trilled, complaining notes, "kee-ee-ee-rr-rrrrrrrr" or "dee'd'd'd'd'd'd'a", slightly descending and ending abruptly, lasts c. 1-1.5 seconds; call a peculiar, resonant, deep "jyoo" or "cheeu".

**Habitat.** Riverine and várzea forest, especially in or near thickets of *Gynerium* cane or *Guadua* bamboo; locally in *terra firme* forest in bamboo patches. Mostly from near sea-level to 500 m; locally to 1300 m.

**Food and Feeding.** Diet primarily Orthoptera, Coleoptera, and spiders; Heteroptera and small tree-frogs also recorded. Usually forages in pairs, regularly to only occasionally in mixed-species flocks, in dense undergrowth to lower mid-storey. Acrobatically gleans and pulls arthropods from dead leaves and debris. Dead-leaf specialist: at a site in SE Peru, more than 90% of all observed foraging manoeuvres involved searching of dead leaves, c. 40% of which were in bamboo thickets; at another locality there, 100% of foraging manoeuvres were directed at dead leaves.

**Breeding.** Two males in breeding condition in Feb in Venezuela (Amazonas). Nest not described; territory size in SE Peru c. 2-3 ha. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Restriction to linear habitat, namely riverine areas, naturally limits its global population. Occurs in several protected areas, including Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Cristalino State Park, in Brazil.

**Bibliography.** Angehr & Auca (1997), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Gyllenstein (1945a), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Kratter & Parker (1997), Munn (1985), Novaes (1958), Parker & Bailey (1991), Parker *et al.* (1982), Pinto (1978), Remsen (2003a), Remsen & Parker (1983, 1984), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rodner *et al.* (2000), Rosenberg (1997), Schulenberg *et al.* (2001), Sick (1993, 1997), da Silva *et al.* (1990), Snyder (1966), Stotz *et al.* (1996), Terborgh *et al.* (1984), Tostain *et al.* (1992), Willard *et al.* (1991), Zimmer, J.T. (1935a), Zimmer, K.J. *et al.* (1997).

## Genus *HYLOCRYPTUS* Chapman, 1919

### 221. Henna-hooded Foliage-gleaner

*Hylocryptus erythrocephalus*

**French:** Anabate à tête orange

**Spanish:** Ticotico Cabecirrufo Occidental

**German:** Westlicher Rötelbaumpäher

**Other common names:** Tawny-headed Hylocryptus

**Taxonomy.** *Hylocryptus erythrocephalus* Chapman, 1919, Alamor, 4300 feet [c. 1300 m], Peru-Ecuador border.

Has sometimes been placed in genus *Automolus*. Race *palambiae* known from only few specimens; quantitative analysis may show that it is not diagnosable. Two subspecies recognized.

**Subspecies and Distribution.**

*H. e. erythrocephalus* Chapman, 1919 - SW Ecuador (coastal cordillera in SW Manabí and W Guayas, also El Oro and W Loja) and extreme NW Peru (Tumbes).

*H. e. palambiae* J. T. Zimmer, 1935 - NW Peru (Piura, Lambayeque).

**Descriptive notes.** 22 cm; 42-51 g. Large, distinctively patterned, handsome, long-billed foliage-gleaner. Has nearly uniform orange-rufous face slightly paler than crown, hint of slightly paler supercilium, lores light greyish; crown rufous, faint paler shaft spotting on forehead; broad rufous collar on nape and upper back, faintly paler than crown; rest of back sharply demarcated, dull olive grey-brown, rump and uppertail-coverts rufous; wings nearly uniform rufous; tail nearly square, shafts slightly stiffened basally, nearly rounded tips, slightly darker rufous than rump; throat, malar area and side of neck light cinnamon-rufous;

breast and belly light greyish-olive, sides and flanks slightly darker, undertail-coverts rufous; iris orange-brown to light brown to grey to greenish-white (source of variation uncertain); upper mandible dark grey-brown, grey or blackish-grey, lower mandible greyish-pink, blue-grey, whitish or pale horn (source of variation uncertain); tarsus and toes olive, olive-grey or grey. Sexes alike. Juvenile has narrow dark feather tips on crown and underparts. Race *palambiae* is slightly paler rufous on head, slightly duller brown on back. **Voice.** Song a distinctive, mechanical, staccato "tok-tok-tok-tok-tok-tok" or "kree-kruh-kruh-kruh-kruh-kruh-kurt". Call a nearly continuous "dee dee dee"; short series of low "tic" notes also given.

**Habitat.** Tropical deciduous forest with dense understorey and thick leaf-litter layer; often in ravines and long strips of riparian woodland; also in disturbed woodland remnants and even scrub. Mostly 600-1300 m, locally down to 150 m and up to 1900 m.

**Food and Feeding.** Invertebrates; isopods recorded. Forages singly or in pairs, regularly in mixed-species flocks, mostly on or close to ground. Gleans food items from ground and leaf litter, often rummaging through litter by flaking and tossing leaves; occasionally forages in low vegetation, rummaging in dead leaves, or briefly hitches up small tree trunks.

**Breeding.** Season reported to be in Jan-May in Ecuador; nestlings in Mar and Apr in Peru. Presumably monogamous. Nest at end of tunnel c. 1 m long in dirt bank. No further information available.

**Movements.** Presumably resident, but local seasonal movements suspected.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Tumbesian Region EBA. Rare to fairly common; very local. Population recently estimated at 2500-10,000 individuals; declining as a result of habitat destruction. Occurs in three protected areas: in SW Ecuador, rare in Machalilla National Park and present in Cerro Blanco Forest Reserve; in NW Peru, common in Tumbes National Reserve. Much or most of original deciduous forest in this region has been destroyed or severely degraded. Continuing habitat loss and degradation, including through illegal activities in officially protected areas, a major threat. Nevertheless, this species persists in highly degraded forest and woodland remnants.

**Bibliography.** Becker *et al.* (2000), Begazo *et al.* (2001), Berg (1994), Chapman (1919, 1926), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cook (1996), Cory & Hellmayr (1925), Parker & Carr (1992), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Paynter (1972), Remsen (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Parker (1981), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Walker (2002), Wege & Long (1995), Wiedenfeld *et al.* (1985), Zimmer (1935b, 1936c).

### 222. Chestnut-capped Foliage-gleaner

*Hylocryptus rectirostris*

**French:** Anabate à bec droit

**German:** Östlicher Rötelbaumpäher

**Spanish:** Ticotico Cabecirrufo Oriental

**Other common names:** Henna-capped Foliage-gleaner, Straight-billed Automolus

**Taxonomy.** *Opetiorynchus rectirostris* Wied, 1831, Campos Geraes on the Bahia-Minas Gerais border, Brazil.

Formerly placed in genus *Automolus*, even after recognition of present genus. Monotypic.

**Distribution.** Interior SC Brazil (C Mato Grosso, S Goiás and extreme S Bahia S to SW Minas Gerais, extreme E São Paulo and NW Paraná) to E Paraguay (San Pedro).

**Descriptive notes.** 20-21 cm; 44-51 g. Large, long-billed foliage-gleaner with fairly uniform plumage. Has chestnut face, light rufous moustachial area; crown chestnut, blending to vague collar of slightly paler reddish-chestnut, and to rich ochraceous brown back and rump; uppertail-coverts chestnut; wings mostly dark rufous; tail slightly rounded, rectrices with nearly rounded tips, chestnut; throat pale rufous, blending to slightly darker breast and belly; flanks darker rufous; brown, undertail-coverts reddish-rufous; iris sulphur-yellow; bill dark grey, paler base of lower mandible; tarsus and toes greyish. Sexes

alike. Juvenile undescribed. **Voice.** Calls include loud "wat", ka, ka, ka", and "co-co-co-rec" like domestic chicken.

**Habitat.** Gallery forest, locally in deciduous woodland; 200-1000 m.

**Food and Feeding.** Arthropods. Forages solitarily or in pairs, perhaps occasionally in mixed-species flocks. Mostly terrestrial; gleans items from ground, presumably mainly in leaf litter.

**Breeding.** Presumably monogamous. Nest of dry leaves and grass (form not described), placed at end of horizontal tunnel excavated in dirt bank. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon. Rather poorly known species.

**Bibliography.** Anon. (2003j), Betini *et al.* (1998), Hayes (1995), Kirwan *et al.* (2001), Marini (2001), Marini, Motta-Júnior *et al.* (1997), Melo-Júnior *et al.* (2001), Paynter (1972), Pinto (1978), Remsen (2003a), Ridgely & Tudor (1994), Sick (1993, 1997), Storer (1989), Stotz *et al.* (1996).

## Genus *SCLERURUS* Swainson, 1827

### 223. Tawny-throated Leaf-tosser

#### *Sclerurus mexicanus*

**French:** Sclérure à gorge rousse **German:** Rostkehl-Laubbwender **Spanish:** Tirahojas Mexicano  
**Other common names:** Tawny-throated/Mexican Leafscraper

**Taxonomy.** *Sclerurus mexicanus* P. L. Slater, 1857, Córdoba, Veracruz, southern Mexico. Plumage similarities have suggested to most authors that this and *S. ruficularis* are sister-species. Apparent elevational parapatry in E Panama of lowland race *andinus* and highland *obscurior* suggests that more than one species may be involved. Racial identity of birds from W slope of E Andes in Colombia uncertain; tentatively included with *peruvianus* but possibly belong with *andinus*. Proposed races *certus* (Guatemala) and *anomalus* (E Panama) are considered not diagnosable. Seven subspecies recognized.

#### **Subspecies and Distribution.**

*S. m. mexicanus* P. L. Slater, 1857 - SE Mexico (from Veracruz) S to N Nicaragua.  
*S. m. pullus* Bangs, 1902 - highlands of Costa Rica and W Panama (E to Veraguas and Coelá).  
*S. m. andinus* Chapman, 1914 - lowlands of E Panama (Panamá E to Darién and San Blas), locally in N Colombia (E to Perijá Mts), extreme NW & S Venezuela and W Guyana (tepui region).  
*S. m. obscurior* Hartert, 1901 - highlands of E Panama in Darién (Cerro Pirre, Tacarcuna and Mali), and W Andes from W Colombia S to SW Ecuador (El Oro, W Loja).  
*S. m. peruvianus* Chubb, 1919 - W Amazonia locally from S Colombia (base of E Andes on W slope in Santander, on E slope S from W Meta) S to E Peru, W Brazil (Amazonas, Acre, N Rondônia) and N Bolivia (S to NW Santa Cruz).  
*S. m. macconnelli* Chubb, 1919 - the Guianas and N Brazil (E from R Negro and, S of R Amazon from R Tapajós E to Maranhão and S locally to N Mato Grosso).  
*S. m. bahiae* Chubb, 1919 - coastal E Brazil (Alagoas S to NE São Paulo).

**Descriptive notes.** 15-17 cm; 24-30 g. A dark, rather plain furnariid with perhaps relatively the longest and thinnest bill in the family. Nominative race has dark brownish, faintly grizzled face; crown dark rich brown, blending to slightly paler, redder back; rump and uppertail-coverts dark chestnut; wings nearly uniform dark reddish-brown; tail rounded, broad, shafts of rectrices stiffened, tips sometimes lacking barbs for distal 1-2 mm. sooty blackish with faint reddish-brown margins; throat and malar area dull rufous-chestnut, upper breast darker chestnut, lower breast to undertail-coverts nearly uniform chestnut-

brown; iris dark brown to brown; upper mandible black to brownish-black, lower mandible black, dark grey or whitish to dull brownish-horn, with black tip; tarsus and toes black to brown. Distinguished from very similar *S. ruficularis* mainly by much longer bill. Sexes alike. Juvenile is duller, with paler shaft streaks on breast, dusky scaling on throat and breast. Race *pullus* is like nominate, but upperparts darker brown, rump more reddish, throat paler, less reddish, breast and belly darker brown, less reddish; *andinus* is lighter brown throughout, rump and uppertail-coverts brighter reddish-brown; *obscurior* is darker, more dusky throughout, with less contrast between throat and breast, reddish-chestnut of uppertail-coverts darker and more restricted; *peruvianus* lacks bright chestnut on rump and uppertail-coverts, which barely more rufescent than back; *macconnelli* differs from last in much more intensely tawny-rufous throat, extending into breast, more generally olivaceous colour throughout; *bahiae* apparently differs from previous in having darker brown upperparts, deep rufous rump contrasting with back, darker throat and chest, and darker brown, less olivaceous breast. **VOICE.** Song a descending set of 4-9 high-pitched, wheezy notes, fading and accelerating, "peeeeeee-peece-peece-chrrrr"; race *pullus* described as descending series of sharp "squee" notes, or descending series of progressively shorter whistled notes "pseer-pseer-pseer-pseer-pse"; *peruvianus* a descending, slightly decelerating series of high, plaintive, clear, whistled "suweet" notes, often with terminal trill, lasts c. 3 seconds; unclear whether variation due to differences in descriptions or genuine geographical variation. Alarm a sharp "squee", "zick", "tseéct" or "chick".

**Habitat.** Tropical lowland and montane evergreen forest, usually in hilly areas. Mainly 700-2200 m in Middle America; in South America from near sea-level to 1500 m, locally to 2000 m.

**Food and Feeding.** Invertebrates. Singly, occasionally in pairs. Terrestrial; hops on ground (does not walk); tail tips often pressed to substrate. Gleans, pecks and probes food items from moist ground, leaf litter and rotting logs; flakes and tosses leaf litter to expose prey.

**Breeding.** Season Dec-Apr in Costa Rica; egg in oviduct in Apr in Mexico; eggs in Apr in French Guiana. Presumably monogamous. Nest a loose cup of dry twigs placed at end of tunnel c. 50 cm long, probably excavated by the birds, in dirt bank; territory size near Manaus (Brazil) c. 25 ha from radio-telemetry studies. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon throughout range; distribution seems patchy in many parts of range. Estimated density 1-6 birds/km<sup>2</sup> at four sites in French Guiana. Occurs in numerous protected areas. Disappears from fragmented or selectively logged forests.

**Bibliography.** Anon. (1998a), Barnett *et al.* (2002), Binford (1989), Chapman (1926), Cory & Hellmayr (1925), Graves & Zusi (1990), Goldenstone (1945a), Haverschmidt & Mees (1994), Hilty (1997, 2003a), Hilty & Brown (1986), Howell & Webb (1995a), Monroe (1968), Parker *et al.* (1982), Pinto (1978), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins *et al.* (1985), Rodner *et al.* (2000), Rowley (1984), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schmitt & Schmitt (1987), Schulenberg *et al.* (2001), Sick (1993, 1997), da Silva *et al.* (1990), Slud (1964), Snyder (1966), Stiles (1985), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer (2003), Stouffer & Bierregaard (1995), Terborgh *et al.* (1984), Thiollay (1986, 1992, 1994), Tostain *et al.* (1992), Wetmore (1951, 1972), Zimmer (1930, 1934e).

### 224. Short-billed Leaf-tosser

#### *Sclerurus ruficularis*

**French:** Sclérure à bec court **German:** Zimtkehl-Laubbwender **Spanish:** Tirahojas Piquicorto  
**Other common names:** Short-billed Leafscraper

**Taxonomy.** *Sclerurus ruficularis* Pelzelin, 1868, Borba, Amazonas, Rio Madeira, Brazil. Plumage similarities have suggested to most authors that this and *S. mexicanus* are sister-species. Four subspecies recognized.

#### **Subspecies and Distribution.**

*S. r. fulvicularis* Todd, 1920 - S Venezuela (Amazonas, Bolívar), the Guianas and N Brazil (probably in Roraima).  
*S. r. brunescens* Todd, 1948 - SE Colombia (S from Meta and Vaupés), W Brazil N of R Amazon (E to possibly right bank of R Negro), E Ecuador and NE Peru (N of R Amazon in Amazonas, Loreto and San Martín).  
*S. r. furfuriosus* Todd, 1948 - N Brazil N of R Amazon (E from possibly R Negro).  
*S. r. ruficularis* Pelzelin, 1868 - S of R Amazon in NE Peru (N Loreto), Brazil (Amazonas E to Maranhão, S to N Mato Grosso) and E Bolivia (E Beni, NE Santa Cruz).

**Descriptive notes.** 15-16 cm; 19-25 g. Nominative race has face dark brownish, faintly grizzled; crown dark brown with reddish tones, very faint darker feather margins; back dark reddish-brown, blending to dark chestnut-brown rump and even darker uppertail-coverts; wings nearly uniform dark reddish-brown; tail rounded, broad, shafts of rectrices stiffened, tips sometimes lacking barbs for distal 1-2 mm, sooty blackish with faint reddish-brown margins; throat and malar area dull orange-rufous, blending to more richly and deeply coloured upper breast with faint, narrow paler shaft streaking; breast becomes darker, less chestnut posteriorly, blending to rich reddish-brown belly and flanks, slightly darker undertail-coverts; iris dark grey-brown to brown; upper mandible black to grey, lower mandible usually bicoloured, distal half black or grey, basal half pinkish or grey; tarsus and toes black to brownish to grey. Distinguished from very similar *S. mexicanus* mainly by much shorter bill (shortest in genus). Sexes alike. Juvenile has duller, browner rump and uppertail-coverts. Race *fulvicularis* differs from nominate in having brown areas more olivaceous (less reddish), paler throat, darker upper breast with broad, blurry rufous shaft streaks; *brunescens* is like previous but generally darker, less rufescent, especially on underparts; *furfuriosus* is described as generally paler in coloration, both above and below. **VOICE.** Song a high-pitched fast series of notes that descend, then ascend and accelerate, and then level out and decelerate; call a sharp "suip".

**Habitat.** Tropical lowland evergreen forest, *terra firme*. From near sea-level to 500 m, locally to 900 m; recorded once to 1800 m in Colombia.

**Food and Feeding.** Invertebrates; alate termites (Isoptera) recorded. Usually solitary. Terrestrial; hops on ground, does not walk. Gleans items from ground and leaf litter; flakes litter to expose prey.

**Breeding.** Nest not described, apparently similar to that of congeners; territory size near Manaus (Brazil) c. 17 ha from radio-telemetry studies. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to locally uncommon; fairly common in S Venezuela; distribution patchy. Estimated density 1-4 birds/km<sup>2</sup> at four sites in French Guiana. Occurs in numerous protected areas. Disappears from fragmented or selectively logged forests.

**Bibliography.** Boesman (1998), Cadena, Álvarez *et al.* (2000), Cardiff (1983), Cory & Hellmayr (1925), Fitzpatrick & Willard (1982), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Novas (1990), Oren (1990), Parker *et al.* (1982), Pinto (1978), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman *et al.* (1999), Schubart *et al.* (1965), Sick (1993, 1997), da Silva *et al.* (1990), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Thiollay (1986, 1992, 1994), Todd (1948b), Tostain *et al.* (1992), Willard *et al.* (1991).

### 225. Scaly-throated Leaf-tosser

#### *Sclerurus guatemalensis*

**French:** Sclérure écaillé **German:** Fleckenbrust-Laubbwender **Spanish:** Tirahojas Guatemalteco  
**Other common names:** Guatemalan Leaf-tosser, Scaly-throated/Guatemalan Leafscraper

**Taxonomy.** *Tinactor guatemalensis* Hartlaub, 1844, no locality = Guatemala.

This and *S. caudacutus* thought by most authors to be sister-species on basis of plumage similarities and parapatric ranges. Substantial individual variation in characters used to define races; suspected that all differences may be a combination of clinal and individual variation, and that naming of geographical races thus not warranted; *ennosphyllus* intergrades with *salvini* in Atrato Valley (Colombia). Three subspecies recognized.

#### **Subspecies and Distribution.**

*S. g. guatemalensis* (Hartlaub, 1844) - S Mexico (from Veracruz) S to C Panama (Colón).  
*S. g. salvini* Salvadori & Festa, 1899 - E Panama (Panamá to Darién), NW Colombia (N Chocó) and W Ecuador (Esmeraldas S to SW Manabí, formerly to N Guayas).  
*S. g. ennosphyllus* Wetmore, 1951 - N Colombia (Antioquia E to Bolívar)

**Descriptive notes.** 16-18 cm; 29-38 g. Scaly pattern on throat more conspicuous than in congeners. Has dark brownish face, some rufescent flammulations on auriculars; malar area and neck side rufescent brown with darker feather margins, producing vaguely scaly look; crown dark brown with slightly darker feather margins, appearing faintly scalloped; back to uppertail-coverts rich dark brown, darkest at tips of tail-coverts; wings nearly uniform rich dark brown; tail rounded, broad, shafts of rectrices stiffened, tips sometimes lacking barbs for distal 1-2 mm, sooty blackish; chin whitish with faint dark lower margins, throat whitish with increasingly conspicuous blackish feather margins that produce scaly look; breast dull reddish-brown with short, broad rufous shaft streaks in centre, rest of underparts nearly uniform dark brown, undertail-

more olive. **Voice.** Song a fast series of 10-15 sharp, clear, whistled notes, "pwik wuk-wuk-wuk-wuk-wuk", rising and accelerating somewhat in middle, then decelerating slightly; also described as ending in accelerating, ascending tinkling notes; longer series (5-6 seconds) of ascending notes also given, often repeated many times in rapid succession. Call a very sharp "pick", "shweek" or "wheel".

**Habitat.** Tropical lowland evergreen forest with sparse undergrowth; locally tall second growth, locally also montane evergreen forest. From near sea-level to 1000 m, locally to 1250 m.

**Food and Feeding.** Invertebrates. Forages singly, occasionally in pairs. Terrestrial; hops on ground, tail tips often pressed to substrate; does not walk. Gleans and probes moist ground, leaf litter and rotting logs; flakes leaf litter to expose prey.

**Breeding.** Eggs in Apr in Honduras and May and Oct-Dec in Costa Rica; nestlings in Jan, Mar and Jun in Costa Rica and Mar in Panama. Monogamous. Nest a shallow cup of leaf stems, usually rachides of compound leaves, placed in expanded chamber at end of curving tunnel 0.5-1 m long, excavated in dirt bank, occasionally in dirt bound into root-mass of fallen tree. Clutch 2 eggs; incubation by both sexes, estimated period at least 21 days; nestling period 14-15 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to rare throughout range. Population in Ecuador recently listed as vulnerable, main threat being forest destruction and fragmentation caused by agricultural expansion; present in Machalilla National Park, and possibly still in Rio Palenque Science Centre.

**Bibliography.** Anon. (1998a), Becker & López (1997), Binford (1989), Burton (1975), Chapman (1926), Cory & Hellmayr (1925), England (2000), Hilty & Brown (1986), Howell & Webb (1995a), Kiff (1996), Monroe (1968), Parker *et al.* (1994), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins, Capparella *et al.* (1991), Robbins, Parker & Allen (1985), Robinson *et al.* (1999), Russell (1964), Skutch (1966, 1969c, 1985), Slud (1960, 1964), Stiles (1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Walters (1995), Wetmore (1951, 1972), Willis (1980), Willis & Eisenmann (1979).

## 226. Black-tailed Leafthorser

### *Sclerurus caudacutus*

**French:** Sclérure des ombres **German:** Weißkehl-Laubwender **Spanish:** Tirahojas Colinegro  
**Other common names:** Black-tailed Leafscraper

**Taxonomy.** *Thamnophilus caudacutus* Vieillot, 1816. French Guiana.

This and *S. guatemalensis* thought by most authors to be sister-species on basis of plumage similarities and parapatric ranges. Validity of race *insignis*, described from a single locality, seems questionable. Geographical distribution of races, particularly N of R Amazon, not well understood, and individual variation in many of the characters used to describe most of them may lead to substantial revision of boundaries; specimens from R Purús (W Brazil) intermediate between *pallidus* and *brunneus*; further, proposed race *olivascens* (from SC Peru) evidently not diagnosable, probably represents clinal variation within latter (specimens from SW Amazonia less reddish on average than those farther N). Critical revision of races and their boundaries badly needed. Five subspecies recognized.

**Subspecies and Distribution.**

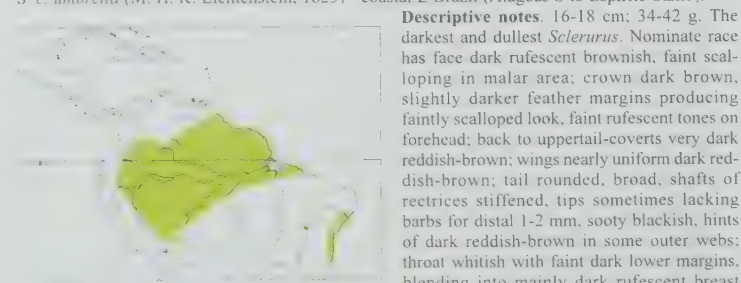

*S. c. brunneus* P. L. Selater, 1857 - W Amazonia from SE Colombia (S from W Meta and Vaupés) and S Venezuela S to E Ecuador, E Peru, W Brazil (W Amazonas, Acre, Rondônia) and N Bolivia (Pando, NW La Paz).

*S. c. caudacutus* (Vieillot, 1816) - the Guianas.

*S. c. insignis* J. T. Zimmer, 1934 - N Brazil N of R Amazon (NW Pará; probably more widespread).

*S. c. pallidus* J. T. Zimmer, 1934 - C Brazil S of R Amazon (E from at least R Madeira to W Maranhão).

*S. c. umbretta* (M. H. K. Lichtenstein, 1823) - coastal E Brazil (Alagoas S to Espírito Santo).

(some continuation of throat pattern on uppermost breast), and to almost blackish-brown rest of underparts; iris brown to dark brown; upper mandible black to blackish-brown, lower mandible usually bicoloured, with pale grey, creamy or pinkish base and grey to black tip; tarsus and toes black to dark brown. Sexes alike. Juvenile is slightly darker throughout, has smaller, duller throat patch with darker feather margins. Race *insignis* is described as like nominate but upperparts duller, less rufous-brown; *brunneus* is slightly paler, more olivaceous throughout, throat duller with broader, more brownish (less blackish) margins, variable, more reddish in N of range, legs sometimes dull reddish-tinged; *pallidus* is paler in general coloration, throat white with dusky tips, breast and face ochraceous brown (not dark brown); *umbretta* is like nominate but throat feathers pure white, each feather with dusky tip, chest duller, less rufescent, lower breast and belly browner (much darker overall than nearest Amazonian races). **Voice.** Song a series of 10-12 loud, ringing, descending "kweet" or "whee" notes, usually introduced by low sputtering trill; call a sharp "skweeup".

coverts slightly darker; iris dark brown to brown; upper mandible black to dark grey, lower mandible usually bicoloured, with pinkish, greyish-horn or yellowish-horn base, dark grey to black tip; tarsus and toes black to blackish-brown to grey. Sexes alike. Juvenile has less regular margins on throat feathers, is slightly darker throughout, breast sometimes tinged ochraceous. Race *salvini* is like nominate, but upperparts and belly darker and more sooty, less reddish, breast markings narrower and less conspicuous; *ennosiphylus* is described as like previous but paler and greyer above, paler below, outer webs of primaries

**Habitat.** Tropical lowland evergreen forest; *terra firme*. From near sea-level to 500 m; locally to 950 m in E Ecuador and to 1100 m in Venezuela.

**Food and Feeding.** Invertebrates: cockroach (Blattodea) oothecae, also Coleoptera, annelid worms and ants reported. One record of a fallen fruit eaten. Usually observed singly. Terrestrial; hops on ground, does not walk. Gleans and probes ground and leaf litter; flakes litter to expose prey.

**Breeding.** Nestlings in Jun in S Peru. Monogamous. Nest a shallow cup c. 13 cm in diameter, made of leaf petioles, placed in enlarged chamber at end of straight tunnel 50 cm long, probably excavated by the birds themselves, in dirt bank; estimated territory size 18 ha. Clutch 2 eggs; both parents feed nestlings.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common. Estimated densities of 6 birds/km<sup>2</sup> in transitional forest in SE Peru and 5-10/km<sup>2</sup> at four *terra firme* sites in French Guiana. Occurs in a number of protected areas, e.g. Imataca Forest Reserve and El Dorado, in Venezuela, Cuyabeno Reserve, in Ecuador, and Cristalino State Park, in Brazil. Disappears from fragmented or selectively logged forests.

**Bibliography.** Angehr & Aueca (1997), Barnett *et al.* (2002), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1925), Denton & Blue-Smith (2000), Foster *et al.* (1994), Goeldi (1896), Graves & Zusi (1990), Gyldestolpe (1945a, 1951), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Munn & Terborgh (1979), Novaes (1990), Oren (1990), Oren & Parker (1997), Parker & Bailey (1991), Parker & Goerck (1997), Parker *et al.* (1982), Pinto (1953, 1978), Remsen & Traylor (1989), Renssen (1974), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rodner *et al.* (2000), Salaman *et al.* (1999), Schubart *et al.* (1965), Schulenberg *et al.* (2001), Scott & Brooke (1985), Sick (1993, 1997), da Silva *et al.* (1990), Snyder (1966), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stotz, Pequeño *et al.* (2002), Stouffer & Bierregaard (1995), Terborgh *et al.* (1984), Thiollay (1986, 1992, 1994), Tostain *et al.* (1992), Zimmer, J.T. (1934e), Zimmer, K.J. *et al.* (1997).

## 227. Grey-throated Leafthorser

### *Sclerurus albicularis*

**French:** Sclérure à gorge grise **German:** Graukehl-Laubwender **Spanish:** Tirahojas Gorgigris  
**Other common names:** Grey-throated Leafscraper

**Taxonomy.** *Sclerurus albicularis* P. L. Selater and Salvin, 1868, Cumbre de Valencia, Carabobo, Venezuela.

Plumage similarities and biogeography suggest that *S. scansor* may be its sister-species. Pattern of geographical variation generally conforms to Gloger's Rule, with plumage darker in warm, humid areas than in colder, drier ones. Within nominate race, population in Trinidad and Tobago significantly smaller than mainland populations. Racial identity of birds from SW Brazil (Acre, N Rondônia) and others reported from S Bolivia (Tarija) uncertain; presumed to belong to *albicollis*. Proposed race *kunanensis*, of Perijá Mts (Colombia-Venezuela border), described as having belly more greenish-olive, remiges more olivaceous and rectrices blackish, but appears indistinguishable from nominate. Six subspecies recognized.

**Subspecies and Distribution.**

*S. a. canicularis* Ridgway, 1889 - foothills of Costa Rica and W Panama (W Chiriquí).

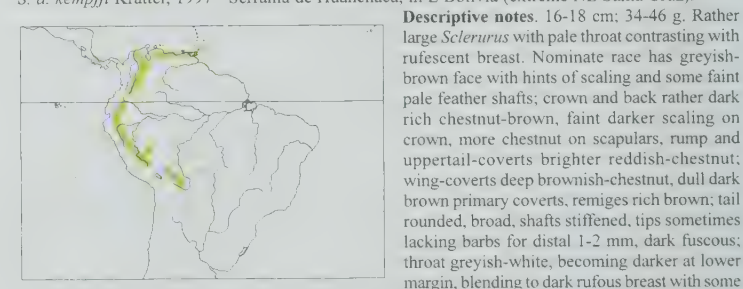

*S. a. propinquus* Bangs, 1899 - Santa Marta Mts, in N Colombia.

*S. a. albicularis* P. L. Selater & Salvin, 1868 - Perijá Mts, also S in E Andes of Colombia (E slope S to E Cauca, also Macarena Mts) and locally in foothills of W & N Venezuela (Andes, coastal range E to Sucre on Paria Peninsula); also Trinidad and Tobago.

*S. a. zamorae* Chapman, 1923 - foothills of Andes from E Ecuador (S from W Napo) S to C Peru (Cajamarca S to Pasco).

*S. a. albicollis* Carriker, 1935 - SE Peru (Ucayali), SW Brazil (Acre, N Rondônia) and Andean foothills in Bolivia (from La Paz and Beni S to NW Santa Cruz, also sight records from Tarija).

*S. a. kempffii* Kratter, 1997 - Serranía de Huanchaca, in E Bolivia (extreme NE Santa Cruz).

**Descriptive notes.** 16-18 cm; 34-46 g. Rather large *Sclerurus* with pale throat contrasting with rufescent breast. Nominative race has greyish-brown face with hints of scaling and some faint pale feather shafts; crown and back rather dark rich chestnut-brown, faint darker scaling on crown, more chestnut on scapulars, rump and uppertail-coverts brighter reddish-chestnut; wing-coverts deep brownish-chestnut, dull dark brown primary coverts, remiges rich brown; tail rounded, broad, shafts stiffened, tips sometimes lacking barbs for distal 1-2 mm, dark fuscous; throat greyish-white, becoming darker at lower margin, blending to dark rufous breast with some paler shaft streaking; belly dull brown, flanks and undertail-coverts richer brown; iris dark brown to brown; upper mandible black to dark grey, lower mandible usually all pale, greyish-white to pinkish to dull yellowish, sometimes bicoloured, with black or grey tip; tarsus and toes black to brown. Sexes alike. Juvenile is duller throughout, throat faintly scaled dusky. Race *propinquus* is like nominate, but upperparts much darker, breast and belly darker, throat greyer; *canicularis* is even darker for the most part, although rufous areas brighter than in both previous and nominate; *zamorae* is generally darker than nominate, rump and uppertail-coverts duller chestnut, contrasting less with back, chin less whitish, upper breast brighter, belly darker; *albicollis* differs from previous in having brighter, more rufescent upperparts, uppertail-coverts rich rufous, contrasting strongly with back, paler underparts, throat white; *kempffii* is palest, has greyer breast and belly, less rufescent upper breast and back, rump colorous with back. **Voice.** Song a series of 4-6 tripled rising notes, "kwu-kwu-kwe-kwe-kwi-kwi", sometimes musical trills interspersed and at end; also described as series of squeaky, plaintive, ascending, whistled notes, "tuée, tuée, tuée, tweéptu" (nominate race and *albicollis*). Alarm a squeaky, sharp "cheek" or "chik-chik".

**Habitat.** Montane and tropical lowland evergreen forest; mainly foothill and lower montane forest, often in shady ravines. Mostly 600-2000 m in Central America and Andean foothills; locally up to 2200 m and down to 50 m in NE of range.

**Food and Feeding.** Recorded dietary items are Coleoptera, spiders, cockroaches (Blattodea), and tiny frogs. Singly, occasionally in pairs. Terrestrial; hops on ground, does not walk; tail tips often pressed to substrate. Gleans and probes moist ground, leaf litter and rotting logs; flakes leaf litter to expose prey.

**Breeding.** Breeds in Oct-May, with peak Dec-Feb, in Trinidad; eggs in May-Jun in N Colombia. Presumably monogamous. Nest at end of typically curving tunnel 0.3-0.5 m long in dirt bank, enlarged chamber c. 20 cm in diameter lined with a few loose leaf rachides. Clutch 2 eggs.

**Movements.** Resident.

**Bibliography.** Anon. (1993a), Angehr & Aueca (1997), Aledo & Ginés (1950), Belcher & Smooker (1936), Bond (1945), Chapman (1926), Collins & Araya (2002), Cory & Hellmayr (1925), Iñeren (1991), Ejeldsá & Krabak (1990), Ejeldsá & Majer (1996), Foster *et al.* (1994), Hayes *et al.* (1998), Herklotz (1961), Hilty (2003a), Hilty & Brown (1986), Kratter (1997c), Kratter *et al.* (1992), Meyer de Schauensee (1959), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Remsen & Traylor (1989), Remsen *et al.* (1986), Renjifo *et al.* (1997), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schmitt & Schmitt (1987), Sick (1993, 1997), Slud (1964), Snow (1985), Stiles (1985), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1984), Todd & Carrier (1922b), Verrea *et al.* (1999), Wetmore (1972), Whittaker & Oren (1999), Zimmer, J.T. (1930, 1934), Zimmer, K.J. *et al.* (1997).

**Bibliography.** Aleixo & Galletti (1997), Anon. (1998a), Barnett *et al.* (2002), Canevari *et al.* (1991), Cory & Hellmayer (1925), Cuello (1985), Delgado (1985), Fjeldså & Krabbe (1990), Fjeldså & Majler (1996), Goeldi (1894), Graves (1985), Hayes (1995), Hilty (2003a), Hilty & Brown (1986), Marini, Motta-Júnior *et al.* (1997), Mazar Barnett & Pearman (2001), Melo-Júnior *et al.* (2001), Meyer de Schauensee (1945), Mitchell (1957), Moschione (1993), Narosky *et al.* (1983), Olivares (1969), Olog (1963a, 1979c), Parker & Goerck (1997), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Parrini *et al.* (1999), de la Peña (1988), Phelps & Phelps (1947), Pinto (1978), Rasmussen *et al.* (1996), Rensen & Traylor (1989), Rensen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman, Donegan & Cuervo (1999), Salaman, Stiles *et al.* (2002), Schäfer & Phelps (1954), Scott & Brooke (1985), Sick (1993, 1997), Silveira (1988), Stotz *et al.* (1996), Wetmore (1926, 1972), Willard *et al.* (1991), Willis (1992b), Willis & Schuchmann (1993), Zimmer (1930).

## PLATE 30

## Family FURNARIIDAE (OVENBIRDS) SPECIES ACCOUNTS

### Genus *HELIOBLETUS* Reichenbach, 1853

#### 230. Sharp-billed Treehunter

##### *Heliobletus contaminatus*

**French:** Sittine à bec fin **German:** Ockerbrauen-Baumspäher **Spanish:** Ticotico Estriado  
**Other common names:** Sharp-billed Xenops, Fulvous-browed Sharp-bill

**Taxonomy.** *Heliobletus contaminatus* Berlepsch, 1885. Nova Friburgo, Rio de Janeiro, Brazil. Species originally named as *H. superciliosus*, then as *Anabates contaminatus*, but that a *nomen nudum*. Genus sometimes merged into *Xenops*; only minor differences between the two in plumage characters, but major differences in vocalizations suggest that they are not closely related. Although both are often placed at end of traditional linear sequences, evidently because of the unusual bill and branch-foraging adaptations, it seems more likely that they were independently derived from various lineages elsewhere within Furnariidae; for example, they are reasonably similar in plumage pattern to other acrobatically foraging genera such as *Premnornis*, *Siptornis*, *Anabacerthia*, *Syndactyla* and *Cichlocolaptes*. Nominate race intergrades with *camargoi* in N São Paulo. Two subspecies recognized.

##### **Subspecies and Distribution.**

*H. c. contaminatus* Berlepsch, 1885 - SE Brazil (S Minas Gerais and Espírito Santo S to N São Paulo and Rio de Janeiro).

*H. c. camargoi* da Silva & Stotz, 1992 - SE Brazil (São Paulo S to Rio Grande do Sul), E Paraguay (Canendiyú, Alto Paraná) and NE Argentina (Misiones).

**Descriptive notes.** 12-13 cm; 13-15 g. Small furnariid closely resembling a xenops. Nominate race has broad golden-buff supercilium, sharply defined blackish-brown postocular band becoming slightly paler posteriorly, extending to hindneck; auriculars dull buff, lores grizzled dark brownish and ochraceous buff; side of neck yellowish-buff; crown blackish-brown with broad golden-olive streaks, these extending to centre of hindneck; buff partial collar formed by extension of colour of supercilium and neck side towards centre of upper back; rest of back and rump dull olive-brown, uppertail-coverts tipped rufous; wings olive-brown, darker primary coverts, remiges faintly tinged rufescent; tail nearly square, rectrices not appreciably stiffened, tips somewhat pointed and distal 1 mm without barbs, dark rufous; throat pale yellowish-buff; breast paler with dull olive-brown streaks, fading in dull olive-brown belly, undertail-coverts dull brownish

with very broad rufous streaks; iris dark brown; upper mandible mostly brown to black, lower mandible pinkish-grey; tarsus and toes greenish-grey to dull yellow-green. Sexes alike. Juvenile has markings less distinct, supercilium and streaking more ochraceous. Race *camargoi* has broad pale golden-buff shaft streaks on back that fade posteriorly, broader and more extensive streaks on lower breast and belly, also significantly shorter wing and tail. **Voice.** Song a short, harsh, metallic slow trill on one pitch, sometimes interspersed with squeaky notes or tinkling overtones; call note a soft "tick".

**Habitat.** Montane and tropical lowland evergreen forest; from near sea-level to 1830 m.

**Food and Feeding.** Arthropods. Forages singly or in pairs, usually in mixed-species flocks, from mid-storey to canopy, often in dense vine tangles; occasionally down to understorey. Acrobatically gleans, pecks and pulls food items from mossy branches, leaves and epiphytes; uses climbing and hanging manoeuvres, but evidently does not use tail for support.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common in much of its range; rare in Paraguay. In Brazil, fairly common in Aparados da Serra and Serra dos Órgãos National Parks and uncommon in Itatiaia National Park; present in Matas dos Godé State Park. In Paraguay, present in San Rafael National Park. Extensive deforestation within its relatively small range has dramatically reduced area of available habitat.

### Genus *XENOPS* Illiger, 1811

#### 231. Rufous-tailed Xenops

##### *Xenops milleri*

**French:** Sittine à queue rousse **German:** Rotschwanz-Baumspäher **Spanish:** Picolezna Colirrufo  
**Other common names:** Miller's Xenops

**Taxonomy.** *Microxenops milleri* Chapman, 1914, foot of Mount Duida, 700 feet [c. 210 m], Amazonas, Venezuela.

Formerly placed in monotypic genus *Microxenops*; differs from current congeners in lacking laterally compressed, wedge-shaped bill, black in tail and pale malar mark, also in leg colour, but shares with them a conspicuous wingband. Monotypic.

**Distribution.** SE Colombia (S from Meta and Vaupés), S Venezuela (Amazonas, S Bolívar), Surinam and French Guiana S to Amazonian Brazil (S to N Rondônia and SW Pará), E Ecuador, E Peru and NW Bolivia (Pando, extreme NW La Paz).

**Descriptive notes.** 10–11 cm; 12–13 g. Tiny furnariid, more like a miniature *Heliobletus contaminatus* than like its congeners. Has buff supercilium with dark flecking above eye, blackish-brown postocular band, blackish-brown auriculars with golden-buff flammulations; crown blackish-brown with conspicuous golden-buff shaft streaks; back dark rufescent brown with wide buff shaft streaks, these fading posteriorly, blending to more rufescent rump and uppertail-coverts; wing-coverts blackish with rufescent brown margins, blackish-brown primary coverts, blackish remiges with broad rufous wingband visible at base; tail nearly square, rectrices without appreciable shaft stiffening and rounded tips, dark rufous; chin pale yellowish-buff, blending to throat and malar area with dark olive flecks and stripes, these increasing in breadth and integrity posteriorly, leading into brighter buff breast with well-defined but narrow dark olive-brown streaks, these fading posteriorly; belly bright golden-buff with dense but light brownish streaking; flanks darker with fewer streaks, undertail-coverts like belly and flanks but streaked light ochraceous brown; iris brown to dark brown; upper mandible black to brownish, lower mandible blue-grey to leaden blue; tarsus and toes yellowish-brown to olive. Sexes alike. Juvenile undescribed. **Voice.** Song a very fast, high, ascending trill, becoming louder, then fading and descending, duration c. 2 seconds; call undescribed.

**Habitat.** Tropical lowland and flooded evergreen forest; mainly *terra firme*, locally also *várzea* forest. From near sea-level to 600 m, locally to 1000 m.

**Food and Feeding.** Arthropods; Orthoptera recorded. Usually seen singly, in mixed-species flocks, in canopy and subcanopy. Rapidly hitches along slender branches, mostly horizontal or inclined, mostly 2–8 cm in diameter, often in vine tangles, with side-to-side searching motion; hangs down to search sides and undersides of branches; tail rarely (if ever) used for support. Gleans food items from bark, moss and dead leaves; data so far indicate that it does not hammer bark as do others of genus.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to locally fairly common. Patchy distribution probably at least in part an artifact of difficulty in detection. Occurs in numerous protected areas, including Amacayacu National Park, in Colombia, Cuyabeno Reserve, in Ecuador, and Tambopata-Candamo Reserved Zone, in Peru.

**Bibliography.** Chapman (1917), Cory & Hellmayr (1925), Foster *et al.* (1994), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Parker (1982), Parker & Bailey (1991), Parker & Hoke (2002), Parker, Castillo *et al.* (1991), Parker, Parker & Plenge (1982), Pinto (1978), Remsen & Robinson (1990), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins *et al.* (1991), Rodner *et al.* (2000), Sick (1993, 1997), Skutch (1985), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stotz, Pequeño *et al.* (2002), Terborgh *et al.* (1984), Tostain *et al.* (1992), Vaurie (1971b), Zimmer *et al.* (1997).

## 232. Slender-billed Xenops

### *Xenops tenuirostris*

**French:** Sittine des rameaux

**German:** Streifenschwanz-Baumspäher

**Spanish:** Pícolzna Picofino

**Taxonomy.** *Xenops tenuirostris* Pelzel, 1859, Salto do Jirau, Rio Madeira, Rondônia, Brazil. Racial assignment of birds from Venezuela tentative; currently included in *acutirostris* but apparently unlike typical specimens of that race; specimens from Guyana also included with *acutirostris* but possibly belong to *hellmayri*; further research required. Three subspecies recognized.

#### Subspecies and Distribution.

*X. t. acutirostris* Chapman, 1923 - W Guyana, S Venezuela (S Amazonas, Bolívar) and SE Colombia (S from Caquetá and Vaupés) S to NE Peru.

*X. t. hellmayri* Todd, 1925 - Surinam and French Guiana.

*X. t. tenuirostris* Pelzel, 1859 - SE Peru, Amazonian Brazil (S of R Amazon) and N Bolivia (Pando, NW La Paz, N Santa Cruz).

**Descriptive notes.** 10 cm; 9–11 g. Wedge-shaped bill relatively longer and thinner and streaking generally finer than in congeners. Nominate race has narrow buffish-white supercilium, blackish-brown postocular band, blackish-brown auriculars with dull buff flammulations; short malar streak gleaming white; crown dark brown, dull buff spotting on forecrown becoming narrow streaks on rest of crown; back rufescent brown with short, broad creamy buff spot-like streaks, these quickly vanishing on lower back; rump and uppertail-coverts reddish-rufous; wing-coverts dark brown with rufous margins, remiges

blackish-brown with rufous wingband showing broadly near bases; tail nearly square, shafts without appreciable stiffening, tips more or less rounded, outer and central pairs of rectrices rufous, others a striking complex mix of black and rufous; chin dull pale buff, blending to throat with dull olive-brown streaking along lower margin; breast dull olive-brown with well-defined pale buff streaks, belly like breast but streaks much narrower, fading posteriorly; undertail-coverts dull olive-brown with broad pale buff shaft streaks; iris brown to dark brown; upper mandible black, sometimes dark brownish, lower mandible black with creamy grey to pinkish base; tarsus and toes dark blue-grey to black. Sexes alike. Juvenile undescribed. Race *acutirostris* has back slightly darker with larger streaks, underparts slightly darker, more greyish-olive, with broader, more sharply defined whitish streaks, bill more slender and not so recurved; *hellmayri* is evidently like nominate, but crown slightly darker and more distinctly streaked, supercilium, neck and throat bright

buff (not whitish), underparts more brownish. **Voice.** Song a series of 4–5 dry “tsip” notes on same pitch.

**Habitat.** Tropical lowland and flooded evergreen forest; mostly sea-level to 600 m, locally to 1500 m.

**Food and Feeding.** Arthropods; Orthoptera recorded. Usually forages singly, in mixed-species flocks, in canopy and subcanopy. Climbs and hitches up and along slender branches, often using tail for support. Hammers, chisels and gleans bark and dead wood.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to locally uncommon. Not well known. Occurs in numerous protected areas, e.g. Manu National Park and Biosphere Reserve, in Peru.

**Bibliography.** Angehr & Aucca (1997), Braun *et al.* (2003), Chapman (1917, 1926), Cory & Hellmayr (1925), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee (1945), Parker & Hoke (2002), Parker *et al.* (1982), Pinto (1978), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Skutch (1985), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stotz, Pequeño *et al.* (2002), Tostain *et al.* (1992), Vaurie (1971b), Willis & Oniki (1990), Zimmer, J.T. (1936c), Zimmer, K.J. & Hilty (1997), Zimmer, K.J. *et al.* (1997).

## 233. Plain Xenops

### *Xenops minutus*

**French:** Sittine brune

**German:** Braunbauch-Baumspäher

**Spanish:** Pícolzna Menudo

**Taxonomy.** *Turdus minutus* Sparrman, 1788, no locality = Rio de Janeiro, Brazil.

Smaller and pale-throated nominate race distinctive, possibly a separate species from others. Apparent geographical variation in song requires further study; several species may be involved. Thorough analysis may reveal that variation in Central America is clinal; proposed race *cayoensis* (from Belize) considered not diagnosable; Honduran populations of *mexicanus* approach *ridgwayi* in most characters, and latter is very like *littoralis*. Sight records from NW Peru (Tumbes) presumed to refer to last-mentioned race. Race *remoratus* intergrades with *ruficaudus* in S Venezuela (R Casiquiare region). Ten subspecies tentatively recognized.

#### Subspecies and Distribution.

*X. m. mexicanus* P. L. Sclater, 1857 - S Mexico (from Veracruz) S to Honduras.

*X. m. ridgwayi* Hartert & Goodson, 1917 - Nicaragua S to C Panama.

*X. m. littoralis* P. L. Sclater, 1862 - E Panama (Darién) and N Colombia (E to Cauca and Magdalena valleys) S to W Ecuador and extreme NW Peru (Tumbes).

*X. m. olivaceus* Avelado & Pons, 1952 - Perijá Mts of NE Colombia and NW Venezuela.

*X. m. neglectus* Todd, 1913 - NE Colombia (S to Cundinamarca) and NW Venezuela (E to Miranda).

*X. m. remoratus* J. T. Zimmer, 1935 - E Colombia (E from Meta and Caquetá), SW Venezuela (SW Amazonas) and NW Brazil (NW Amazonas).

*X. m. ruficaudus* (Vieillot, 1816) - E Colombia (Vichada), S & E Venezuela (Amazonas and Bolívar E to Paria Peninsula), the Guianas and N Brazil (E of R Negro).

*X. m. obsoletus* J. T. Zimmer, 1924 - E Ecuador, E Peru, W Brazil (S of R Amazon, E to R Madeira) and N Bolivia (S to N Santa Cruz).

*X. m. genibarbis* Illiger, 1811 - C Brazil (R Madeira E to Piauí, S to S Mato Grosso and N Goiás).

*X. m. minutus* (Sparrman, 1788) - E & SE Brazil (Pernambuco S to Santa Catarina), E Paraguay (E from Canendiyú, Caaguazú) and NE Argentina (Misiones).

**Descriptive notes.** 11–12 cm; 9–13 g. Short, wedge-shaped bill; the only member of genus without prominent streaking and with graduated tail. Nominate race has buffish-white supercilium and weak eyering, blackish-brown auriculars variably flammulated with dull buff; gleaming white posterior malar streak emphasized by blackish border, anterior portion buff with some blackish-brown bases showing through; crown rather dark warm brown with faint paler brown shaft streaks; back and rump slightly paler, tinged rufescent, blending to dull dark rufous uppertail-coverts; wing-coverts rich brown with blackish centres, blackish primary coverts with rufous-tawny outer webs, remiges blackish-brown with broad rufous-tawny wingband near base; tail slightly graduated, shafts without appreciable stiffening, tips rounded, outer and central pairs of rectrices rufous, others a striking complex mix of black and rufous; throat white, hint of dull brownish streaks beginning along lower margin; underparts medium brown, deeper and richer on sides, flanks and undertail-coverts, short, blurry buff streaking on upper breast; iris brown to dark brown; upper mandible black to brownish-horn, lower mandible ivory to pinkish or greyish at base, blending to dark grey tip; tarsus and toes dark grey to blue-grey. Sexes alike. Juvenile has slightly less distinct pattern throughout, throat slightly clouded greyish. All races are substantially larger than nominate, with proportionately larger bill, darker throat, more heavily marked breast; *genibarbis* has throat feathers edged olivaceous rather than cleanly whitish, wingband darker ochraceous; *obsoletus* is like previous, but crown less rufescent and with paler broader streaks, lower back more olivaceous, tail slightly paler rufous, throat slightly more heavily edged with brownish, breast spotting more extensive (differs from next in being more olivaceous above, head not distinctly darker than back and with narrower streaks, rump brighter than back, central rectrices paler, underparts slightly duller with narrow breast markings); *ruficaudus* has crown darker, less rufescent, with distinct narrow buff shaft streaks, underparts more olivaceous, neck and upper breast more heavily spotted, more pronounced brownish edges on throat feathers; *remoratus* differs from last in generally duller colour, crown not conspicuously streaked, breast markings less sharply defined; *neglectus* differs from previous (and other races to E) in having slight yellowish tinge on throat, more olivaceous underparts; *olivaceus* is described as very similar to last but even more olivaceous, less greyish-brown, below; *littoralis* differs from it evidently only in being slightly darker throughout (differs from nearest Amazonian races in having more extensive white on throat, breast streaks extending farther down); *ridgwayi* differs from previous in having more rufescent rump and uppertail-coverts; *mexicanus* differs from last in having back and crown slightly more rufescent, rump and uppertail-coverts brighter, more intense chestnut-rufous, throat whiter, less yellowish-tinged, breast and belly tinged rufescent (less olivaceous). **Voice.** Song a series of 8–10 high, staccato “sweet” or “pseep” notes, slightly ascending and then descending, accelerating and then decelerating; race *littoralis* song faster (compared with Amazonian races), ascending “tsi”

notes; *mexicanus* described as high-pitched, rapid, liquid trill, introduced by 1-4 "pip" notes; *ridgwayi* as rattling trill, slowing at end, often introduced by 1-2 call notes, often repeated. Calls described as fine, sharp "pee" or "peet" and thin "tseep" or "tsiss".

**Habitat.** Tropical lowland and flooded evergreen forest; locally in tropical deciduous forest and gallery forest. From near sea-level to 1000 m, locally to 1500 m.

**Food and Feeding.** Recorded dietary items are insect eggs, termites (Isopoda), spiders, ants and their larvae, other Hymenoptera, Dermaptera, katydids (Tettigoniidae), millipedes (Diplopoda), and Coleoptera (Xylopidae). Forages usually singly, sometimes in pairs, usually in mixed-species flocks, in understorey. Climbs and hitches up and along branches (perhaps especially woody vines) usually 2-10 cm in diameter, sometimes using tail for support; often along underside of branch, or hanging downwards; frequently forages at broken-off terminal tips of branches, including downward-hanging ones. Acrobatically hammers, chisels and gleans bark and dead wood, and occasionally dead leaves. Many manoeuvres directed at opening decaying twigs, often those caught up in branches by vine tendrils attached to them, sometimes large, dead leaf petioles, to reach adult and larval insects in centre; lengthens openings in such twigs by inserting bill and pushing forwards.

**Breeding.** Season Dec to at least Jun in Costa Rica and Panama, also active nest in Sept (Panama); possibly two broods per year. Monogamous. Nest-hole excavated by pair in soft decaying wood of tree branch or trunk, mostly 3-10 m up, nest-chamber lined with soft plant fibres; holes made by other species, e.g. piculets (*Picumnus*) also used; estimated territory size 9 ha in transitional forest in SE Peru. Clutch 2 eggs; incubation by both sexes, period 15-17 days; chicks fed by both parents, nestling period 13-14 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common in most of its huge range. Estimated densities of 12-30 birds/km<sup>2</sup> in transitional forest in SE Peru and 8-13/km<sup>2</sup> in *terra firme* forest in French Guiana. Occurs in numerous protected areas throughout its extensive range. In some areas tends to disappear from disturbed forests, but in others appears tolerant of some disturbance.

**Bibliography.** dos Anjos *et al.* (1997), Anon. (1998a), Avelado & Pons (1952), Binford (1989), Canevari *et al.* (1991), Chapman (1971), Chehez (1994), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Greenberg & Gradwohl (1985), Haverschmidt & Mees (1994), Hayes (1995), Hilty (1997, 2003a), Hilty & Brown (1986), Howell & Webb (1995a), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1945, 1959), Monroe (1968), Munn (1985), Narosky *et al.* (1983), Parker & Bailey (1991), Parker & Carr (1992), Parker & Goerck (1997), Parker, Holst *et al.* (1994), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), de la Peña (1988), Pinto (1978), Rappole & Morton (1985), Remsen (2003a), Remsen & Traylor (1989), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robbins & Ridgely (1990), Robbins *et al.* (1985), Robinson, S.K. & Terborgh (1997), Robinson, S.K. *et al.* (1990), Robinson, W.D. *et al.* (1999), Rodner *et al.* (2000), Russell (1964), Schubert *et al.* (1965), Schulenberg (2002), Schulenberg *et al.* (2001), Scott & Brooke (1985), Sick (1993, 1997), da Silva, Lima & Marceliano (1990), da Silva, Oren *et al.* (1997), Skutch (1969c, 1985), Slud (1960, 1964), Snyder (1985), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1994), Todd & Carriker (1922b), Tostain *et al.* (1992), Vaurie (1971b), Veree *et al.* (1999), Wetmore (1972), Willis (1960a, 1980), Willis & Eisenmann (1979), Winker *et al.* (1994), Zimmer (1930, 1935b, 1936c).

## 234. Streaked Xenops

### *Xenops rutilans*

**French:** Sittine striée **German:** Strichelscheitel-Baumspäher **Spanish:** Picolesna Rojizo

**Taxonomy.** *Xenops rutilans* Temminck, 1821, Brazil.

Geographical variation over species' large range slight, despite number of named races; in fact, there seems to be more variation within nominate than among many of proposed races. Highly likely that many or most races are not diagnosable; majority were described from few specimens and few localities, and many of the characters used to define them seem invalid. Racial identity of birds from extreme E Peru and NE Bolivia (Pando) and others from extreme E & SE of latter country uncertain: the first are tentatively included with *purusianus* and the second with *connectens*. Listed distributions of several races should be interpreted with caution. Eleven subspecies very tentatively recognized.

**Subspecies and Distribution.**

*X. r. septentrionalis* J. T. Zimmer, 1929 - Costa Rica and W Panama (W Chiriquí).

*X. r. incomptus* Wetmore, 1970 - extreme E Panama (Cerro Pirre).

*X. r. phelpsi* Meyer de Schauensee, 1959 - Santa Marta Mts, in N Colombia.

*X. r. perijanus* Phelps, Sr. & Phelps, Jr., 1954 - Perijá Mts, and E Andes of W Venezuela (S Táchira) and NE Colombia (Santander).

*X. r. heterurus* Cabanis & Heine, 1859 - N Venezuela (E to Paria Peninsula), Trinidad, and E Andes from Colombia (S from Cundinamarca) S to NE Ecuador.

*X. r. guayae* Hellmayr, 1920 - lowlands of W Ecuador (S from Esmeraldas) and NW Peru (Tumbes, Piura).

*X. r. peruvianus* J. T. Zimmer, 1935 - Andean foothills in Ecuador and Peru (S to Puno).

*X. r. purusianus* Todd, 1925 - extreme E Peru, C Brazil (R Purús E to R Tapajós) and NE Bolivia (Pando).

*X. r. connectens* Chapman, 1919 - foothills from Bolivia (S from La Paz, also in extreme E & SE) S to NW Argentina (S to Tucumán).

*X. r. chapadensis* J. T. Zimmer, 1935 - E Bolivia (Beni) and SW Brazil (Rondônia and Mato Grosso E to Maranhão, Piauí and Goiás).

*X. r. rutilans* Temminck, 1821 - SE Brazil (S from Bahia and Minas Gerais) S to NC Paraguay and NE Argentina (Misiones, NE Corrientes).

**Descriptive notes.** 12 cm; 10-15 g. Along with *X. milleri* the most broadly streaked member of genus, also with short, thick, wedge-shaped bill. Nominative race has conspicuous pale buff supercilium, blackish-brown postocular band, dark brownish auriculars with dull buff streaking, lores grizzled blackish and dull grey-buff; malar streak gleaming white, emphasized by dark brownish borders, anterior malar yellow-buff; crown dark brown with conspicuous rufous shafts streaks; back rufescent brown with inconspicuous paler rufous streaks that fade posteriorly, rump and uppertail-coverts chestnut-rufous; wing-coverts rufescent brown with darker inner webs, primary coverts very dark brown with outer edges rufescent brown, remiges dark fuscous with outer webs tinged rufous (central remiges rufous only at base and tip); tail nearly square, shafts not stiffened and tips almost rounded, chestnut-rufous, with blackish on inner web of rectrix 3; throat and centre of uppermost breast whitish, mottled; rest of breast and belly with broad buffy whitish streaks outlined with dark brownish, streaks narrow and fading (with paler brown outlining) on lower belly and flanks, flanks tinged rufescent; iris brown to dark brown; upper mandible dark brown to blackish, lower mandible whitish to pinkish-grey, often with blackish tip; tarsus and toes grey to black. Sexes alike. Juvenile has less distinct pattern throughout, dark areas of tail not so black, pale area of throat slightly clouded greyish and more restricted. Race *chapadensis* is like nominate, but

in having no black in tail (except at concealed bases), also pale areas of throat, breast and belly faintly tinged yellowish (less pure white), olive-brown portions of underparts brighter, more buff-tinged; *guayae* is tawnier, more ochraceous buff below than any other race; *phelpsi* is described as most like previous but less heavily streaked; *perijanus* differs from last in duller upperparts, more black on third rectrix, more greyish-olive (less brownish) underparts; *incomptus* (perhaps known only from two specimens) is described as being smaller, streaking above and below reduced and narrow, upperparts deeper cinnamon (especially rump and tail-coverts), underparts grey-toned; *septentrionalis* has slightly duller, less rufescent underparts and back than *peruvianus*. **VOICE.** Song an ascending and then descending, high-pitched series of 5-10 dry, squeaky "swee" or "zeet" notes, accelerating at end, sometimes (possibly only in Trinidad) with emphatic terminal note. Call a high, piercing "peet" or "cheet".

**Habitat.** In Andes mainly montane evergreen forest and hilly deciduous forest, at 700-2400 m (locally to 2800 m); in lowlands a variety of humid to semi-arid forest and woodland types, from tropical deciduous forest to tropical lowland evergreen forest, including second growth. In Middle America habitat range similar, and mainly 540-2450 m.

**Food and Feeding.** Arthropods; Coleoptera larvae recorded. Forages singly or in pairs, often to usually in mixed-species flocks, from understorey (at edge) to subcanopy. Climbs and hitches up, along and under slender branches, mostly less than 10 cm in diameter, sometimes using tail for support. Acrobatically gleans, hammers, chisels, and flakes bark and decaying wood.

**Breeding.** Season Jan-May in Costa Rica; breeding recorded Feb-May, with eggs in May, in Trinidad. Presumably monogamous. Nest consists of only a few root fibres or shredded plant fibres, placed in natural cavity or in old hole of piculet (*Picumnus*), or cavity excavated in soft wood, 1.5-9 m up in tree. Clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in most of its range. Densities estimated at 8 birds/km<sup>2</sup> in transitional forest in SE Peru; estimated at 34/km<sup>2</sup> in forest reserve in SE Brazil, declining to 7/km<sup>2</sup> in small forest fragments. Occurs in numerous protected areas throughout its extensive range. Appears fairly tolerant of habitat disturbance; survives in small and degraded forest fragments, although in some cases at lower densities.

**Bibliography.** dos Anjos *et al.* (1997), Anon. (1998a), Belcher & Smoother (1936), Belton (1984), Bond (1945), Canevari *et al.* (1991), Chapman (1971, 1926), Cory & Hellmayr (1925), French (1991), Fjeldså & Krabbe (1990), Fjeldså & Majer (1996), Foster *et al.* (1994), Gyldestolpe (1945b, 1951), Haverschmidt & Mees (1994), Hayes (1995), Hayes *et al.* (1990), Hilty (2003a), Hilty & Brown (1986), Mazar Barnett & Pearman (2001), Meyer de Schauensee (1959), Miller (1963), Munn (1985), Narosky *et al.* (1983), Olrog (1963a), Parker & Carr (1992), Parker & Goerck (1997), Parker, Gentry *et al.* (1993), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1995), Parrini *et al.* (1999), de la Peña (1988), Peters & Griswold (1943), Phelps & Phelps (1954, 1955), Pinto (1948, 1978), Pinto & Camargo (1952), Remsen & Traylor (1989), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rodner *et al.* (2000), Scott & Brooke (1985), Sick (1993, 1997), Skutch (1985), Slud (1964), Stiles (1985), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Taczanowski (1884), Terborgh *et al.* (1984), Tostain *et al.* (1992), Vaurie (1971b), Walker (2001), Wetmore (1970, 1972), Wiedenfeld *et al.* (1985), Zimmer (1930, 1935b, 1936c), Zotta (1938).

## Genus MEGAXENOPS Reiser, 1905

### 235. Great Xenops

#### *Megaxenops paraguayae*

**French:** Mégasittine du Brésil **German:** Zimtrotter Baumspäher **Spanish:** Picolesna Grande  
**Other common names:** Reiser's Recurvebill

**Taxonomy.** *Megaxenops paraguayae* Reiser, 1905, caatinga woods on the trail from Parnaguá to Olho d'Água, Piauí, Brazil.

No obvious close relationships. Although traditionally placed near *Xenops*, this evidently based solely on wedge-shaped bill; foraging behaviour suggests that it is closer to *Philydor* or *Syndactyla*. Monotypic.

**Distribution.** E Brazil, from Piauí, Ceará and W Pernambuco S to W Bahia and NW Minas Gerais.

reasonably sharply demarcated from light orange-rufous underparts, slightly darker on rear flanks, slightly darker and more rufous undertail-coverts; iris dark brown; bill dusky brownish-grey, at least basal half of lower mandible whitish; tarsus and toes dark grey to black. Sexes alike. Juvenile

has more rufescent upperparts, paler and browner margins of white streaks on underparts; *connectens* has much duller, less rufescent upperparts, more olivaceous and less broadly streaked underparts (more like next in general coloration); *heterurus* is duller and less broadly streaked, evidently differs from most others in having inner webs of rectrices 3 and 4 almost entirely black, and some black at base of rectrix 5; *purusianus* is described as similar to previous race but paler and more broadly streaked whitish below, also has throat more conspicuously edged brownish than nominate; *peruvianus* is described as differing from last

in having no black in tail (except at concealed bases), also pale areas of throat, breast and belly faintly tinged yellowish (less pure white), olive-brown portions of underparts brighter, more buff-tinged; *guayae* is tawnier, more ochraceous buff below than any other race; *phelpsi* is described as most like previous but less heavily streaked; *perijanus* differs from last in duller upperparts, more black on third rectrix, more greyish-olive (less brownish) underparts; *incomptus* (perhaps known only from two specimens) is described as being smaller, streaking above and below reduced and narrow, upperparts deeper cinnamon (especially rump and tail-coverts), underparts grey-toned; *septentrionalis* has slightly duller, less rufescent underparts and back than *peruvianus*. **VOICE.** Song an ascending and then descending, high-pitched series of 5-10 dry, squeaky "swee" or "zeet" notes, accelerating at end, sometimes (possibly only in Trinidad) with emphatic terminal note. Call a high, piercing "peet" or "cheet".

**Habitat.** In Andes mainly montane evergreen forest and hilly deciduous forest, at 700-2400 m (locally to 2800 m); in lowlands a variety of humid to semi-arid forest and woodland types, from tropical deciduous forest to tropical lowland evergreen forest, including second growth. In Middle America habitat range similar, and mainly 540-2450 m.

**Food and Feeding.** Arthropods; Coleoptera larvae recorded. Forages singly or in pairs, often to usually in mixed-species flocks, from understorey (at edge) to subcanopy. Climbs and hitches up, along and under slender branches, mostly less than 10 cm in diameter, sometimes using tail for support. Acrobatically gleans, hammers, chisels, and flakes bark and decaying wood.

**Breeding.** Season Jan-May in Costa Rica; breeding recorded Feb-May, with eggs in May, in Trinidad. Presumably monogamous. Nest consists of only a few root fibres or shredded plant fibres, placed in natural cavity or in old hole of piculet (*Picumnus*), or cavity excavated in soft wood, 1.5-9 m up in tree. Clutch 2-3 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in most of its range. Densities estimated at 8 birds/km<sup>2</sup> in transitional forest in SE Peru; estimated at 34/km<sup>2</sup> in forest reserve in SE Brazil, declining to 7/km<sup>2</sup> in small forest fragments. Occurs in numerous protected areas throughout its extensive range. Appears fairly tolerant of habitat disturbance; survives in small and degraded forest fragments, although in some cases at lower densities.

**Bibliography.** dos Anjos *et al.* (1997), Anon. undescribed. **VOICE.** Song a series of bubbly notes that start slowly and quietly, then accelerate and rise in pitch, trailing away at end, lasting c. 3 seconds; also described as 3-4 descending “kiak” notes, sometimes in short series with guttural terminal “gro” notes.

**Habitat.** *Caatinga* and semi-humid woodland and forest; from possibly 200 m to 1100 m.

**Food and Feeding.** Recorded dietary items are Formicidae, beetles (Scarabaeidae), larval Lepidoptera, and arachnids (*Ctenus*, *Micrathena*, *Phoneutria*). Forages solitarily or in pairs, usually or often in mixed-species flocks. Works along branches; unlike *Xenops*, does not climb, hitch, or use tail for support. Searches live leaves, dead leaves and bark; occasionally pries, pulls and chisels bark, but not known to hammer bark and dead wood. One observation of bird investigating termite (Isoptera) nest, sometimes hanging upside-down.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Rare to locally fairly common. Present in Serra da Capivara National Park (Piauí), Chapada do Araripe National Forest (Ceará) and Cavernas do Peruaçu National Park (Minas Gerais). Deforestation has dramatically reduced populations, even to point of local extinction, in some parts of range. Nevertheless, has more extensive range and broader habitat tolerance than was believed in early 1990s; tolerates a certain degree of habitat degradation, including disturbance and heavy grazing, and observed to forage in burnt areas.

**Bibliography.** de Andrade (1990), Bernardes *et al.* (1990), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1925), Hellmayr (1929b), Kirwan *et al.* (2001), do Nascimento *et al.* (2000), Olmos (1993), Parrini *et al.* (1999), Pinto (1978), Pinto & Camargo (1961), Ridgely & Tudor (1994), Siek (1993, 1997), Siek *et al.* (1987), Stotz *et al.* (1996), Teixeira (1989), Teixeira, Nacinovic & Luigi (1989), Teixeira, Nacinovic & Schloemp (1991), Wege & Long (1995), Williams (1995a).

Genus *PYGARRHICHAS* Burmeister, 1837

236. White-throated Treerunner

*Pygarrhichas albogularis*

**French:** Picotelle à gorge blanche **German:** Kleiberbaumspäher **Spanish:** Picolezna Comesebo

**Taxonomy.** *Dendrocolaptes albo-gularis* P. P. King, 1831, no locality = presumably Strait of Magellan, Chile.

Traditionally placed near *Xenops* and other bark-gleaning furnariids, but plumage and biogeography suggest that such a relationship unlikely and that any similarities are due to convergence. Possible relationship to *Aphrastura* suggested by superficial plumage similarities and details of foraging behaviour. Monotypic.

**Distribution.** C & S Chile (from Santiago) and W Argentina (from Mendoza) S to Tierra del Fuego.

**Descriptive notes.** 15-16 cm; 20-27 g. Distinctive, reminiscent of a nuthatch (*Sitta*) in plumage and shape, with ventral pattern unlike that of any other furnariid. Has blackish-brown face, slightly darker than crown; crown dark dull brown, blending to slightly paler back, variably tinged chestnut, and to rufous-chestnut rump and uppertail-coverts; wing-coverts dark brown, variably edged chestnut to rufous (broadly at tips), darker primary coverts, remiges very dark with narrow ochraceous to rufous edges of variable length (broader on bases of tertials), bright chestnut-rufous short wingband on inner primaries; tail rounded, shafts notably stiffened

throughout length, tips with prominent “spines” up to 9 mm long and greatly reduced barbs, rufous-chestnut; throat, broad malar area and upper breast bright white, side of lower breast dark brown; centre of lower breast with dark brown margins producing irregularly scalloped effect, belly similar with fading darker feather margins; flanks broadly dull chestnut with blackish feather bases and some whitish flecking, vent whitish with broad dark brown feather margins, undertail-coverts whitish with broad chestnut and blackish margins; iris dark brown; upper mandible dark horn to dark grey, lower mandible mostly whitish to pale greyish; tarsus and toes dark grey to blackish or brown. Sexes alike. Juvenile has crown and back heavily streaked with ochraceous, often blackish margins on some throat feathers. **VOICE.** Contact call described as loud, agitated, metallic “kik-ik”, “tsi-dik” or “tsik”, often repeated rapidly; loud “peet peet” also given; flight call dry “tick”.

**Habitat.** Tall, humid to semi-humid forest dominated by *Nothofagus*; sea-level to 1200 m.

**Food and Feeding.** Arthropods; adult and larval Coleoptera recorded. Forages sometimes to usually singly, regularly to usually in mixed-species flocks with *Aphrastura spinicauda*, from understorey to canopy. Climbs and hitches up and along branches and trunks; manoeuvres generally similar to those of *Sitta* nuthatches (but very rarely with head down); often uses tail for brace, but also much foraging done with tail elevated from branch. Food items obtained by acrobatically gleaning, probing and chiselling on branches and moss.

**Breeding.** Season presumably during austral spring-summer; eggs in Nov-Dec and nestlings in Dec. Presumably monogamous. Nest-hole excavated in dead branch, usually 3-8 m above ground, cavity 25-40 cm deep, no lining other than wood chips created by excavating (but one report of nest lined with grass and feathers). Clutch 2-3 eggs.

**Movements.** Mainly resident; some wandering in non-breeding season.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common. Occurs in a number of protected areas in Chile, including Vicente Pérez Rosales, Puyehué, Nahuelbuta and Cerro La Campana National Parks; also present in Tierra del Fuego National Park, in Argentina.

**Bibliography.** Araya & Chester (1993), Canevari *et al.* (1991), Contreras (1975), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Grigera *et al.* (1996), Humphrey *et al.* (1970), Johnson (1967), Mazar Barnett & Pearman (2001), Narosky *et al.* (1983), Olog (1963a), de la Peña (1988), Philippi *et al.* (1954), Radboone (1935), Rasmussen *et al.* (1992), Ridgely & Tudor (1994), Short (1969a), Stotz *et al.* (1996), Vuilleumier (1967, 1985).

## Class AVES

## Order PASSERIFORMES

## Suborder FURNARIII

## Family DENDROCOLAPTIDAE (WOODCREEPERS)

- Small to medium-sized birds with broad rounded wings, long tail with rigid shafts, outer and middle toes united and much longer than inner toe, front claws strongly curved; most with brown plumage, a few grey to blackish, all with rufescent wings and tail.
- 13-36 cm.

- Neotropical Region.
- Forest and woodland, a few in semi-open habitats.
- 13 genera, 52 species, 270 taxa.
- 1 species threatened; none extinct since 1600.

**Systematics**

The woodcreepers (Dendrocolaptidae) are part of an endemic Neotropical group of birds known as the tracheophone suboscines. These primitive passerines, which are united by a tracheal syrinx of similar structure, have evolved a diverse array of ecological specializations. Most woodcreepers are specialized tree-climbers, extremely well adapted to an arboreal life. Not surprisingly, their centre of diversity lies in the rich, forested lowlands of the Amazon Basin, where up to 19 species occur together. Members of the family Dendrocolaptidae were formerly known as "woodhewers", a name derived from early accounts that referred to these birds as "picicules", meaning "little woodpeckers" (Picidae). This name, however, was abandoned in favour of one that more appropriately reflects their habits, which seldom include pecking or hammering in the manner of true woodpeckers.

As with most passerines, the fossil record of woodcreepers is scant, providing no insight into the age of their lineage. Only a few Quaternary fossils are known, all from two sites in Brazil. One of these is the Lapa da Escrivania, near Lagoa Santa, Minas Gerais, where one fossil from the Pleistocene, of the White-throated Woodcreeper (*Xiphocolaptes albicollis*), and two others, one Pleistocene and the other Holocene, of the Narrow-billed Woodcreeper (*Lepidocolaptes angustirostris*) have been discovered. According to H. Alvarenga, specimens of *Xiphocolaptes* species have been found at another site in Brazil. J. Cheneval's recent assertion that a middle Miocene fossil, *Homalopus picoides*, first discovered in the mid-nineteenth century at Sansan, in France, represents a dendrocolaptid must be viewed with caution. There is no evidence to suggest that tracheophone suboscines ever existed outside the New World. Any attempt to establish confidently that they did would require more than the extremely fragmentary material available, which includes only the distal end of a left tarsometatarsus and the proximal end of a right humerus. Although the fossil does show certain similarities to tree-climbing birds, S. L. Olson suggested that *Homalopus* might have been an oscine that was only convergently similar to suboscines. Molecular data clearly indicate that the woodcreepers diverged relatively recently from the ovenbirds (Furnariidae), with the split probably occurring during the Miocene.

Evidence from both morphology and molecular genetics strongly supports a monophyletic assemblage including both woodcreepers and ovenbirds, a much larger group of birds that has radiated into a highly diverse array of forms occupying a

variety of niches. This close relationship has resulted in the taxonomic rank of these two groups being unsettled, with many treatments combining them as one family, either under the name Dendrocolaptidae, as in older classifications, or under the name Furnariidae, as in more recent ones; in either case, the woodcreepers have consequently been ranked as a subfamily, the Dendrocolaptinae. Only these two avian families, Dendrocolaptidae and Furnariidae, possess two pairs of intrinsic muscles of the syrinx, the vocalis dorsalis being absent in other tracheophone suboscines. In addition, analyses of both DNA-DNA hybridization data and sequences of nuclear and mitochondrial DNA support the view that the woodcreepers and the ovenbirds form a closely related group that is distinct from other birds. Nevertheless, dendrocolaptids differ from furnariids in a number of features. Characters traditionally used to diagnose woodcreepers include horns on the processus vocalis of the syrinx, these horns lacking in all furnariids except the miners (*Geositta*); bony nostrils that are rounded and do not reach the posterior end of the premaxilla, a condition known as holorhinal; and outer and middle toes that are united at the base, of similar length, and noticeably longer than the inner toe. All woodcreepers share these features to a degree, but not all ovenbirds can be excluded by them. Notably, several "intermediate" woodcreeper genera, namely *Dendrocincla*, *Deconychura*, *Sittasomus* and *Glyphorhynchus*, exhibit a mixture of morphological characters, having some features of "typical" dendrocolaptids and others that are more typical of furnariids; for example, *Dendrocincla* and *Sittasomus* have narrower bony nostrils that resemble the pseudoschizorhinal condition of furnariids. Some authors, therefore, cite the aforementioned four dendrocolaptid genera as demonstrating a clear link between the ovenbirds and woodcreepers.

A diverse array of evidence indicates that all extant woodcreeper genera are more closely related to each other than they are to any furnariid. All dendrocolaptids share a particular configuration of their feather tracts (pterylosis) that distinguishes them from all other passerines. Further, they are unique among the passerines in having extensive ossification of the tendons of the hind limb, an adaptation to their tail-braced, scansorial habits that is reduced or more variable only in the genus *Dendrocincla*, the members of which less frequently adopt scansorial postures. *Platyacarus* feather mites are known to parasitize only woodcreepers, with documented hosts in every genus except the monotypic genera *Sittasomus*, *Glyphorhynchus* and *Drymornis*; this last, containing the Scimitar-billed Woodcreeper (*Drymornis*

*bridgesii*), retains many morphological characters, especially those of the limb muscles, that are primitive among woodcreepers (see Morphological Aspects). DNA-DNA hybridization data, coupled with phylogenetic analyses of various morphological and molecular characters, consistently yield results suggesting that, taken together, all dendrocolaptid genera comprise a monophyletic group. In contrast, Furnariidae appears not to be monophyletic with respect to woodcreepers.

The issue of whether to rank woodcreepers as a separate family has been tackled recently by M. Irestedt and colleagues, whose estimated phylogeny based on both nuclear and mitochondrial DNA suggested that the leaf-tossers (*Sclerurus*) are basal both to woodcreepers and to all other ovenbirds. Because of this arrangement, these authors recommended that the Furnariidae include three subfamilies: woodcreepers (Dendrocolaptinae), leaf-tossers (Sclerurinae), and all other ovenbirds (Furnariinae). An alternative classification, not mentioned by Irestedt and co-workers, would be to accord family rank to each of these groups. The placement of the woodcreepers in a family of their own seems the best course, because woodcreepers form a clearly diagnosable yet diverse group of species that share distinctive morphological and molecular traits. Moreover, incorporation of them within the ovenbird family would create too inclusive a group, comprising nearly 300 species, that obscures important evolutionary differences among its members.

Some scientists have speculated that it was in the vast Amazon Basin that the woodcreepers evolved from their supposed

nearest living relatives, the foliage-gleaners. In his monograph on the relationships of furnariids and dendrocolaptids, A. Feduccia postulated that, on the basis of similarities in anatomy, behaviour and geographical distribution, ancestral woodcreepers were foliage-gleaners that were capable of tree-climbing, an adaptation that may have greatly reduced competition for feeding space in mixed-species foraging flocks. According to this hypothesis, tree-climbing foliage-gleaners then experienced an extensive radiation in this new foraging space, leading eventually to modern woodcreepers.

Shortly after Feduccia's monograph, E. O. Willis, whose extensive observations of woodcreeper behaviour and ecology are perhaps unparalleled, suggested an alternative view of dendrocolaptid evolution. He noted that woodcreepers of the genus *Dendrocincla* and leaf-tossers of the ovenbird genus *Sclerurus* were strikingly similar in both appearance and behaviour. On this basis, he proposed that tree-climbing woodcreepers might have evolved from terrestrial leaf-tosser ancestors lured upwards to exploit food on bare tree trunks in forests, and perhaps driven there through competition with the evolving thamnophilid antbirds that now dominate ant-following flocks in the understorey. Under this scenario, the genus *Dendrocincla* represents a primitive woodcreeper that has advanced little. This apparent link with leaf-tossers was not supported by anatomical analyses of woodcreeper-ovenbird relationships, but evidence of it has emerged recently in analyses of mitochondrial and nuclear DNA sequences. Using these molecular characters, Irestedt and col-

The woodcreepers present one of the stiffest challenges for ornithologists visiting the Neotropics. At first glance, many are confusingly similar in behaviour, shape and colour. As a result, woodcreepers are difficult to identify in the field, or even the museum, and species-level taxonomy is prone to constant revision.

The **Montane Woodcreeper**, for example, has recently been separated from the **Spot-crowned Woodcreeper** (*Lepidocolaptes affinis*). Apart from minor size and plumage differences, these two taxa are vocally distinct.

[*Lepidocolaptes lacrymiger aequatorialis*,  
Bellavista Lodge,  
Tandayapa Valley,  
Ecuador.

leagues have proposed a phylogeny for the tracheophone suboscines. Their study included, among several other taxa, a single leaftosser, the Rufous-breasted Leaftosser (*Sclerurus scansor*), as well as five species of dendrocolaptids, among them the Plain-brown Woodcreeper (*Dendrocincla fuliginosa*). These authors found that the leaftosser emerged as ancestral to all woodcreepers as well as to all other ovenbirds. In spite of sampling limitations, this supports the view that both families may have evolved from a woodcreeper-ovenbird ancestor that bore some similarities to extant species of leaftosser.

On the basis of anatomical and molecular characters, there are two major lineages of woodcreepers. One of these comprises species in the four genera that were considered by Feduccia to be "intermediate" between the Dendrocolaptidae and the Furnariidae: *Dendrocincla*, *Deconychura*, *Sittasomus* and *Glyphorhynchus*. The other lineage, known as the "strong-billed" group, comprises all other dendrocolaptid species. The several characters possessed by the "intermediate" taxa that are thought to be ancestral and are shared with the ovenbirds include less stiffened shafts of the tail feathers and reduced ossification of the leg tendons in *Dendrocincla*, the presence of wingstripes in *Sittasomus* and *Glyphorhynchus*, and particular features of the skull. The "strong-billed" woodcreeper genera exhibit several derived characters, many associated with their ubiquitous creeping behaviour and trunk-foraging lifestyle, such as the "closed" two-notched sternum, a heavily ossified skull, extensive ossification of the leg tendons, and a well-developed pygostyle.

Whether the "intermediate" lineage is basal within the Dendrocolaptidae remains controversial. R. Raikow's estimate of woodcreeper phylogeny, based on characters derived from hind-limb and bill morphology, found that two monotypic genera, *Nasica* and *Drymornis*, emerged as basal to all woodcreepers; *Drymornis* was the more primitive of the two, as determined by its retention of ancestral character states, not by its specialized bill shape and ground-foraging behaviour. By contrast, two recent phylogenetic studies employing both nuclear and mitochondrial DNA sequences supported the placement of *Nasica* and *Drymornis* in the "strong-billed" assemblage. Neither study included both genera in the same analysis with other woodcreepers, one having sampled *Drymornis* and the other only *Nasica*. A possible explanation for the conclusions of the morphological study is that the wide variability in substrates used by tree-climbing birds has led to a great plasticity in anatomical characters associated with feeding and climbing, rendering characters associated with these traits less useful for phylogenetic analysis.

As noted above, woodcreepers in the genus *Dendrocincla* may be the most primitive within the family, a hypothesis reflected in most linear classifications. All six species in this apparently monophyletic genus have rectrices with a somewhat less rigid shaft and a reduced spiny tip when compared with other dendrocolaptid genera, which exhibit typically rigid shafts with prominent bare, spiny tips that are often curved ventrally. Members of this genus do not depend so much on trunk-foraging, instead catching most of their food by sallying like a flycatcher; they use vertical trunks mostly for perching, and perch on horizontal branches more often than do most woodcreepers. Within the genus *Dendrocincla*, species-level taxonomy is in need of study. Widespread species of *Dendrocincla*, such as the Plain-brown and the White-chinned Woodcreepers (*Dendrocincla merula*), have several well-differentiated subspecies, some of which may merit recognition as full species when more comprehensive reviews of geographical variation in genetic and vocal characters become available. Within the White-chinned Woodcreeper, differences in vocal characters, size and iris colour suggest that at least two species may be involved. In view of the vocal and plumage differences documented by Willis, it seems better to treat the Plain-winged Woodcreeper (*Dendrocincla turdina*) of south-eastern Brazil as being distinct from the Plain-brown Woodcreeper, with which it was formerly considered by most authors to be conspecific. Leaving aside *turdina*, the Plain-brown Woodcreeper has at least three other distinctive groups of subspecies, some of which may ultimately be found to be deserving of separate species status.

The name *Dendrocolaptes certhia* once delimited a species with a range extending from Mexico to the southernmost reaches of Amazonia. As knowledge increased, however, it became clear that there were consistent differences in morphology, foraging behaviour and voice between those populations occurring north and west of the Andes and those in Amazonia. So marked are these differences that two species are now recognized: the Amazonian Barred Woodcreeper (which retains the name *D. certhia*), and the Northern Barred Woodcreeper. The latter differs from the former by its rufous cap, blackish bill and lores, and more extensive and better-defined barring on the underparts, although separation in the field is not a problem, as the two never occur together. Had their voices been identical, these morphological differences would probably have been insufficient basis for separating them into two species. However, their voices differ dramatically, which is the most convincing evidence that the two forms would not interbreed if their ranges overlapped.

For centuries, avian classification has been based largely on morphology. Much as this method succeeded in providing a map of diversity for the world's birds, it achieved too rough a sketch of the Dendrocolaptidae. In this family, morphological differentiation between allied taxa is slight, their true relationships only discernible by a thorough analysis of vocalizations and genetics. Because such studies are in their infancy, the emerging patterns of variation are often perplexing, and many taxonomic problems remain unsolved. The **Plain-winged Woodcreeper**, for example, was long considered a race of the Plain-brown Woodcreeper (*Dendrocincla fuliginosa*), but its song differs in pace and pitch to such a degree that the two forms are now usually treated as *allospecies*. They belong in the genus *Dendrocincla*, an apparently monophyletic group of six species that are possibly the most primitive in the family. They have rectrices with a somewhat less rigid shaft and a reduced spiny tip, which may be related to the fact that they tend to depend less on trunk-foraging than most woodcreepers, instead catching most of their food by sallying.

Willis also noted that the plumage and behaviour of the two *Deconychura* species suggest that the genus is intermediate between *Dendrocincla* and *Glyphorhynchus*, with the Spot-throated Woodcreeper (*Deconychura stictolaema*) being closer to the latter genus. In partial agreement with this suggestion, Raikow's phylogenetic hypothesis suggested that the two species of *Deconychura* are not each other's closest relatives, his findings placing them, along with the Olivaceous Woodcreeper (*Sittasomus griseicapillus*), in clades intermediate between *Dendrocincla* and *Glyphorhynchus*. Like the Olivaceous Woodcreeper and the Wedge-billed Woodcreeper (*Glyphorhynchus spirurus*), the two *Deconychura* species were each placed in a separate clade not closely related to any extant dendrocolaptid. Relationships among the ten taxa currently divided between the two species of *Deconychura* remain uncertain. For example, within the Long-tailed Woodcreeper (*Deconychura longicauda*), birds from Central America south to north-central Colombia, forming the "typica group" of subspecies, may be more closely related to the Spot-throated Woodcreeper. Furthermore, there is marked vocal variation within the remaining four, rather morphologically uniform, taxa of the Long-tailed Woodcreeper occurring in Amazonia.

Among the remaining "intermediate" genera, the taxonomy of the Olivaceous Woodcreeper is perhaps the one most in need of a comprehensive, systematic revision of all included taxa. The species can be divided into five major groups based on size and gross plumage coloration. This variation, combined with concordant vocal differences among some groups, is sufficiently marked to suggest that full biological species are involved, this being especially true in the case of three of the groups: each of the two groups occupying eastern Brazil, namely *reiseri* in the north-east and the "sylvellus group" in eastern and south-eastern Brazil, and the disjunct form *aequatorialis* on the Pacific coast of South America. Of the remaining subspecies of the Olivaceous Woodcreeper, some that appear similar to each other have distinct vocalizations, but it is uncertain how this variation should be interpreted. Lastly, the small yet distinctive Wedge-billed Woodcreeper is known to possess at least two geographically distinct song types, although gene flow exists between some morphologically distinct subspecies.

In contrast to the uncertain relationships among the "intermediate" woodcreepers, monophyly of the "strong-billed" clade, exclusive of *Nasica* and *Drymornis* (see above), has been corroborated by a number of investigations. A study of mitochondrial DNA (mtDNA) sequences supported the division of the "strong-billed" woodcreepers into two clades, one containing the genera *Nasica*, *Dendrozetetes*, *Hylexetastes*, *Xiphocolaptes* and *Dendrocolaptes*, and the other consisting of *Campylorhamphus*, *Lepidocolaptes* and *Xiphorhynchus*.

Molecular and anatomical characters strongly indicate a sister relationship between the genera *Hylexetastes* and *Xiphocolaptes*. *Hylexetastes* contains only two species, both confined to the Amazon Basin, whereas the four species of *Xiphocolaptes* are distributed in a variety of forested habitats from Mexico south to central Argentina. Species-level taxonomy within these genera merits further study. In the genus *Hylexetastes*, two species, the Red-billed Woodcreeper (*Hylexetastes perrotii*) and the Barbellied Woodcreeper (*Hylexetastes stresemanni*), have traditionally been recognized, although some authors have elevated the subspecies *uniformis* of the former to a full species, the "Uniform Woodcreeper". In 1995, the taxon *brigidai* was, on the basis of plumage, described as a new species, "Brigida's Woodcreeper", but its appearance is close enough to that of *uniformis* that hybrids would be difficult to detect. Vocal similarity among these and other *Hylexetastes* taxa, coupled with limited morphometric differences, supports treatment of all as subspecies of the Red-billed Woodcreeper. Plumage patterns in *Hylexetastes* are comparable to those in the sympatric populations of the Amazonian Barred Woodcreeper (*Dendrocolaptes certhia*), which appear to constitute a single species.

The four *Xiphocolaptes* have significantly longer bills than do the two *Hylexetastes*, but they are otherwise nearly identical structurally. This morphological similarity is reflected in their placement as sister taxa in a recent phylogeny. Unlike species in the genus *Hylexetastes*, those in the genus *Xiphocolaptes* differ

notably in plumage patterns, less so in size. All members of the genus share similar structure, however, in that they are large and heavy-bodied, with the tail relatively short, and the bill long, massive and laterally compressed. *Xiphocolaptes* formed a monophyletic clade in a phylogenetic analysis that sampled three of the four species. Three species are largely restricted to discrete biogeographical regions, within which geographical variation is subtle. The White-throated Woodcreeper has three subspecies in the Atlantic and Planalto forests of eastern and south-eastern Brazil and adjacent portions of Argentina and Paraguay. The Great Rufous Woodcreeper (*Xiphocolaptes major*), a Chaco species, has four subspecies in Bolivia, south-western Brazil, Paraguay and northern Argentina. The rare Moustached Woodcreeper (*Xiphocolaptes falcirostris*) is distributed spottily in deciduous forests of the Caatinga region of north-eastern Brazil. Unlike its three congeners, the Strong-billed Woodcreeper (*Xiphocolaptes promeropirhynchus*) occurs over a vast range and exhibits tremendous geographical variation in plumage and habitat preference. There are currently 25 recognized subspecies, divided into three groups: the "emigrans group" in Central America, the "promeropirhynchus group" living in the Andes of northern South America, and the "orenocensis group" of the Amazonian lowlands and the foothills of the tepuis. C. Cory and C. Hellmayr hypothesized that the "orenocensis group" is a separate species, the "Great-billed Woodcreeper", and others have raised the possibility that all three groups may represent distinct species. Some taxa in this genus have had a tortuous taxonomic history. Recent analysis of plumage characters revealed that the taxon *franciscanus*, formerly regarded either as a separate species, "Snethlage's Woodcreeper", or as a subspecies of the White-throated Woodcreeper, is instead best treated as the southernmost population of the globally threatened Moustached Woodcreeper. Conversely, a poorly known race of the White-throated Woodcreeper, *villanovae* from north-eastern Brazil, was formerly considered a subspecies of the Moustached Woodcreeper.

The genus *Dendrocolaptes* likewise forms a discrete morphological group, but its affinities to other woodcreepers remain uncertain. Some analyses suggest a close relationship between *Dendrocolaptes* and *Hylexetastes*, but more recent analyses of anatomical characters favour a sister relationship with *Xiphocolaptes* and *Hylexetastes* combined. Analyses of molecular data suggest that *Dendrocolaptes* occupies a basal position relative to the genera *Dendrozetetes* and *Nasica*. Species limits within and between currently recognized species in this genus also remain unsettled. The two barred woodcreepers, which together have populations extending from southern Mexico southwards to the southernmost reaches of Amazonia, were formerly united in a single species, *Dendrocolaptes certhia*, but differences in morphology and voice between populations occurring north and west of the Andes and those in Amazonia are sufficiently marked that two species are now recognized: the Northern Barred Woodcreeper (*Dendrocolaptes sanctithomae*) and the Amazonian Barred Woodcreeper, respectively. By contrast, variation in morphology and voice suggests that the form *concolor*, previously regarded as a separate species under the name "Concolor Woodcreeper", is best treated as a subspecies of the Amazonian Barred Woodcreeper. Species limits within what apparently constitutes a superspecies of streaked birds, the Black-banded (*Dendrocolaptes picumnus*), Planalto (*Dendrocolaptes platyrostris*) and Hoffmann's Woodcreepers (*Dendrocolaptes hoffmannsi*), are uncertain. Morphologically, the little-known Hoffmann's Woodcreeper is unique within the genus, having a longer, slimmer bill and unusual plumage patterns. Although Raikow grouped Hoffmann's with the two barred woodcreepers, its voice, foraging behaviour and biogeography support Willis's assertion that it is more closely related to the Black-banded and Planalto Woodcreepers.

Taxonomic confusion in the Dendrocolaptidae is perhaps best exemplified by the largest genus in the family, *Xiphorhynchus*. This genus has a broad distribution, and its 15 members exhibit a diverse range of body sizes and ecological adaptations. A. Aleixo's recent phylogenetic hypothesis, based on variation in mtDNA, helped to clarify many relationships in this vexing genus while at the same time highlighting further challenges. De-

The statement that both of these photographs show **Olivaceous Woodcreepers**

is true according to current taxonomy, but it may not be true for much longer. Based on differences in size and coloration, at least five major groups of subspecies exist, and some of these groups may well represent full biological species.

The form pictured above is a member of the "griseus group", which occurs in Central America and northern South America; the form below is a member of the "sylvellus group", which is largely confined to the Atlantic forests of eastern South America.

These photos show races from opposite extremes of the range of *Sittasomus* that are characterized by rather marked differences in both plumage coloration and vocalizations. On the other hand, birds in the "griseus group" appear relatively similar to populations in Amazonia and the Chaco ("griseicapillus group"), but these two groups differ dramatically in vocalizations.

Nevertheless, the traditional treatment should not be altered until the relationships of all groups are adequately understood.

[Above: *Sittasomus griseicapillus gracileus*, Tikal, Guatemala.

spite the morphological diversity in the genus, molecular evidence implies that, with the exception of the Straight-billed Woodcreeper (*Xiphorhynchus picus*) and Zimmer's Woodcreeper (*Xiphorhynchus kienerii*), all species of *Xiphorhynchus* share a common ancestor. These results further combine with patterns of gross morphology and aspects of ecology to support the treatment of most species in one of four groups, but the affinities of two additional species remain unclear. The first group comprises an Amazonian radiation of small dendrocolaptids that characteristically follow mixed-species flocks through the understorey. The second group consists of four ecological generalists occurring from Mexico south to southern Amazonia and eastwards to the Atlantic Forest of Brazil; these species are larger than those in the first group, are less tied to the forest understorey, and forage alone or by following either mixed-species flocks or army ants. The third group contains two largely montane species, the Spotted Woodcreeper (*Xiphorhynchus erythropygius*) and the Olive-backed Woodcreeper (*Xiphorhynchus triangularis*), each of medium size and atypical plumage, that may be foraging specialists on mossy trunks.

The Straight-billed and Zimmer's Woodcreepers, representing the fourth group, are sibling species that are sufficiently distinct from other *Xiphorhynchus* to have been treated for many years in the genus *Dendroplex*. The recent genetic analysis suggested that these two are more closely related to the genera *Campylorhamphus* and *Lepidocolaptes*. Notwithstanding this, the return of the Straight-billed and Zimmer's Woodcreepers to their own genus is not straightforward, because an unfortunate nomenclatural problem complicates the use of the name *Dendroplex*. Moreover, the bill of Zimmer's Woodcreeper does not fit the diagnosis for *Dendroplex*, and this species was consequently placed in *Xiphorhynchus* even by authors who still classified the Straight-billed Woodcreeper in *Dendroplex*. Further complicating matters, a recent examination revealed that the holotype of *Dendroornis* [= *Xiphorhynchus*] *kienerii*, described in 1856 and subsequently considered a subspecies of the Straight-billed Woodcreeper, matches *Dendroplex* [= *Xiphorhynchus*] *necopinus*, described in 1934 and known as Zimmer's Woodcreeper. *Dendroplex necopinus* is, therefore, a junior synonym of *Dendroornis kienerii*, and the current scientific name of Zimmer's Woodcreeper becomes *Xiphorhynchus kienerii*. Until these various problems are resolved, it is deemed best to retain the Straight-billed and Zimmer's Woodcreepers in *Xiphorhynchus*.

Affinities of two other species in this genus are uncertain. The Lesser Woodcreeper (*Xiphorhynchus fuscus*), occurring in the Atlantic and Planalto forests of eastern Brazil and adjacent areas in Paraguay and Argentina, was for many years classified in the genus *Lepidocolaptes*. In 1983, Willis suggested that, because of its behaviour, it belonged in *Xiphorhynchus*; more recent analyses of anatomical and molecular characters place its closest relatives as members of the Amazonian radiation that combines the *X. ocellatus* and *X. spixii* species complexes. The Striped Woodcreeper (*Xiphorhynchus obsoletus*) is similar morphologically to species in the radiation of small Amazonian woodcreepers, but genetic analyses have not resolved its affinities.

Hypothesized relationships within each of the four groups of *Xiphorhynchus* woodcreepers are in a state of flux. Although mtDNA data supported the monophyly of the Amazonian radiation in the first group, consisting of the *X. ocellatus* and *X. spixii* superspecies groups, the basal taxon is the Lesser Woodcreeper of the Atlantic Forest. Within this radiation, mtDNA data supported a return to the treatment of the *X. ocellatus* superspecies group as comprising three species: the Chestnut-rumped (*Xiphorhynchus pardalotus*), Ocellated (*Xiphorhynchus ocellatus*) and Tschudi's Woodcreepers (*Xiphorhynchus chunchotambo*). The molecular data likewise supported the results of an independent analysis of plumage by J. Haffer, which indicated that the *X. spixii/elegans* species complex should be recognized as two species, the monotypic Spix's Woodcreeper (*Xiphorhynchus spixii*) of eastern Amazonia and the polytypic Elegant Woodcreeper (*Xiphorhynchus elegans*) of southern and western Amazonia. The latter now includes not only the nominate race and *ornatus*, traditionally recognized within *X. elegans*, but also

racings *juruanus*, *insignis* and *buenavistae*, all of which have traditionally been placed within *X. spixii*.

Even more complicated are the taxonomic issues associated with the second group of widespread generalists, and especially the complex now combining the Buff-throated Woodcreeper (*Xiphorhynchus guttatus*) and the Cocoa Woodcreeper (*Xiphorhynchus susurrans*). The taxa contained in this complex have been treated variously as constituting either one widespread species or as many as three or four different species. The currently recognized division is unsatisfactory and requires further study. Within the Cocoa Woodcreeper, for example, geographical patterns of song types are more complex than was previously realized, and differences in size do not appear to correspond to current species limits. Taxa within the "*susurrans* group", occurring in Trinidad, Tobago and the adjacent Venezuelan mainland and offshore islands, are significantly larger than those within the "*nanus* group" ("Lawrence's Woodcreeper"), which range west from central Venezuela into Central America. Moreover, plumage patterns of the former group are so different that authors who merged taxa in the "*nanus* group" with the remaining South American populations of the Buff-throated Wood-

The recent tendency has been to split species, but the taxonomic status of many woodcreepers still remains to be clarified. For example, based on morphological differences the taxon *eytoni*, currently treated as a race of the

**Buff-throated Woodcreeper**, has been considered a species in its own right, the "Dusky-billed Woodcreeper". Nevertheless, a variety of data, including molecular analysis, support its merger with the western Amazonian populations of the Buff-throated. Although this is the treatment adopted here, there remain such striking mismatches in genetics, plumage and vocalizations in the expanded Buff-throated Woodcreeper complex that it is likely to include more than one allospecies.

[*Xiphorhynchus guttatus* *eytoni*, Imperatriz, Maranhão, Brazil.  
Photo: Haroldo Palo]

Many woodcreeper species have had a convoluted nomenclatural history, and none perhaps more so than **Zimmer's Woodcreeper**.

Long known by the name *Dendroplex* [= *Xiphorhynchus*] *necopinus*, a taxon described in 1934, it went so long without being conclusively identified in the field that its status was questioned. When its validity was proven, museum studies revealed the holotype of *Dendroornis* [= *Xiphorhynchus*] *kienerii* to be the same bird; after its description in 1856, this specimen, and the name, had been mistakenly assigned to the Straight-billed Woodcreeper (*X. picus*). As the first use of *kienerii* thus predates that of *necopinus*, the latter is rendered redundant as a junior synonym.

[*Xiphorhynchus kienerii*,  
Anavilhanas Islands,  
Amazonas, Brazil.  
Photo: Arthur Grosset]

creeper still recognized the Cocoa Woodcreeper proper as being distinct. Molecular analyses suggest that members of the “*nanus* group” are closely related to races of the Buff-throated Woodcreeper occurring in eastern Brazil and in the north-eastern part of Amazonia, these being, respectively, the nominate race and the subspecies *polystictus* and *connectens*. Because members of the “*susurrans* group” were not examined in this study, however, relationships between it and the “*nanus* group” remain uncertain.

Taxonomy is in a state of flux even within the Buff-throated Woodcreeper as presently recognized. Molecular data support the merger of the form *eytoni*, the “Dusky-billed Woodcreeper”, with the western Amazonian populations of the Buff-throated Woodcreeper, a move complemented by variation in plumage coloration but contradicted by marked differences in both bill coloration and vocalizations. These data also indicate a close relationship between the nominate race of the Buff-throated Woodcreeper, from coastal eastern Brazil, and the disjunct forms *polystictus* and *connectens* occurring north of the River Amazon in Brazil, the Guianas and the Orinoco region of southern Venezuela, all to the exclusion of geographically intermediate populations in Amazonia (both the *eytoni* and *guttatoides* subspecies groups). Vocally, the nominate form is relatively similar to populations previously recognized as the Dusky-billed Woodcreeper, with *polystictus* and *connectens* similar but of uncertain affinities. Songs of the western Amazonian forms, by contrast, differ strikingly. It is likely, therefore, that the complex of taxa now recognized as the Buff-throated Woodcreeper includes more than one allospecies, but interpretation of variation in voice, morphology and DNA in this widespread dendrocolaptid is in need of more comprehensive sampling.

The other two species in this group of generalists, the Ivory-billed Woodcreeper (*Xiphorhynchus flavigaster*) and the Black-striped Woodcreeper (*Xiphorhynchus lachrymosus*), both occur largely or exclusively in Central America. Molecular data suggest that they are each other's closest relatives; together, they are the sister to the Buff-throated Woodcreeper complex.

The genus *Lepidocolaptes* is a well-defined group of relatively small woodcreepers, all of which have a slender and

decurved bill. With the Lesser Woodcreeper now placed in *Xiphorhynchus*, as mentioned above, anatomical and molecular data indicate that *Lepidocolaptes* is monophyletic. Although many earlier authors considered South American populations of the Montane Woodcreeper (*Lepidocolaptes lacrymiger*) to be conspecific with the Spot-crowned Woodcreeper (*Lepidocolaptes affinis*), these two taxa differ in voice and plumage. In eastern Brazil, the Scaled (*Lepidocolaptes squamatus*) and Scalloped Woodcreepers (*Lepidocolaptes falcinellus*) are now regarded as separate species. They were formerly combined as northern and southern populations, respectively, of a single species, but they exhibit diagnosable differences in plumage, without showing intergradation where the taxa meet abruptly in south-eastern Brazil. Two of the most widespread species, the Lineated Woodcreeper (*Lepidocolaptes albolineatus*) and the Narrow-billed Woodcreeper, display substantial geographical variation in plumage, and each has many described subspecies. On the basis of plumage differences, Hellmayr hypothesized that populations of the Lineated Woodcreeper from southern, central and western Amazonia, the “*fuscicapillus* group”, represent a distinct species, referred to as the “Dusky-capped Woodcreeper”. The songs of the Lineated Woodcreeper also show marked geographical variation. The remaining two species in this genus are the White-striped Woodcreeper (*Lepidocolaptes leucogaster*), a Mexican endemic, and the Streak-headed Woodcreeper (*Lepidocolaptes souleyetii*), which is widespread in Central America and northern South America. In these two, geographical variation in plumage is far more subtle, and the latter, despite its broad distribution, exhibits little geographical variation in vocalizations.

Genetics and anatomical features support monophyly of the final genus of the Dendrocolaptidae, *Campylorhamphus*. On the basis of mtDNA sequences, the five scythebills are most closely related to the genus *Lepidocolaptes*. Nevertheless, the Greater Scythebill (*Campylorhamphus pucherani*) not only is the sole member of its genus that has not yet been included in any systematic study, but it is also the most divergent, both morphologically and vocally. As seems to be the rule among woodcreepers, both of the widespread species, the Red-billed (*Campylorhamphus*

*trochilirostris*) and the Curve-billed Scythebills (*Campylorhamphus procurvoides*), exhibit marked geographical variation in plumage, song and habitat preference; each may comprise multiple allospecies. Moreover, habitat preferences and vocalizations imply that some Amazonian populations of the Curve-billed Scythebill may be better treated instead as subspecies of the morphologically similar Red-billed.

Because the plumage of woodcreepers is cryptically patterned, and because their anatomy is constrained by foraging behaviour, morphological diagnosis of many species is difficult. There are few avian groups for which the careful analysis of genetic and vocal data is more likely to improve our understanding of systematics and evolution. Future studies must strive to document variation not among a select sample of named taxa but, instead, among populations separated by either vast distances or key barriers to dispersal. Only by using sampling schemes sufficiently thorough to document genetic and vocal variation within populations, and to determine, with a fair degree of certainty, the geographical barriers that correspond to these differences, can one make taxonomic recommendations confidently. As voice is an indirect measure of reproductive isolation, the analysis of vocal data requires a caution similar to, if not greater than, that demanded in the interpretation of genetic data. Before making taxonomic recommendations based on any type of variation, it is necessary to outline geographical patterns in the characters, to develop a benchmark of variation within populations for later comparison among populations, and to determine, with a reasonable degree of certainty, that the characters being studied are, indeed, important in the process of reproductive isolation. It is essential to bear in mind that, although both genetic and vocal data may be important for understanding species limits, these data are subject to the same pitfalls as are morphological data, our understanding of which has had a century longer to develop.

## Morphological Aspects

Although woodcreepers are variable in body size, with a total length ranging from 13 cm to 36 cm, most members of the family share a rather uniform body form and plumage coloration. Bill length and shape account for much of the variation. The bill represents more than a quarter of the body length in the Long-billed Woodcreeper (*Nasica longirostris*), for example, and in the scythebills its extreme curvature results in the distinctive placement of the eyes. The smallest dendrocolaptid is the widespread Wedge-billed Woodcreeper, which, at 13 cm long and weighing 15 g, is not much larger than a *Certhia* treecreeper (Certhiidae). The heaviest is the Strong-billed Woodcreeper, up to 169 g in weight and to 35 cm in length, which is a little larger than a *Colaptes* flicker (Picidae). The majority of woodcreepers are roughly the size of a small thrasher (Mimidae).

Males tend to be larger than females, but broad overlap in both measurements and body mass typifies most dendrocolaptid species. Pronounced sexual dimorphism in size is exhibited only by the Long-tailed and Spot-throated Woodcreepers, the males of which are considerably larger and heavier than the females. Differences in plumage among woodcreepers are slight, both between young birds and adults and between the sexes. In a few species, especially some *Dendrocolaptes*, males are recognizable because they raise their crown feathers frequently, producing a somewhat shaggy crest that creates a noticeably different appearance from that of the sleek-headed females. Sexual dimorphism in plumage is otherwise not apparent.

Juveniles differ subtly from adults, but young birds already resemble adults after their first body moult. Immatures tend to be more barred, have a slightly shorter tail, and have a darker or blacker bill that is significantly shorter than the adult's; the last feature is evident for a relatively longer time than are other characteristics of immaturity.

Woodcreeper plumage does not undergo seasonal change. The only perceivable changes in the feathering are the result of wear and fading, some birds appearing paler late in the breeding season, when many feathers, most notably the remiges and rectrices, are extensively worn.

The predominant coloration of most dendrocolaptids is brown, with the wings and tail contrastingly rufescent. Even such species as the Olivaceous, Olive-backed, Spotted and Black-striped Woodcreepers, which are mostly grey, olive or blackish, exhibit the plain, reddish-brown wings and tail typical of the family. As an overlay on their more subdued coloration, woodcreepers may possess a variegated pattern of streaks, spots and bars on the back, nape, head and underparts. Exceptions to this include the Olivaceous Woodcreeper and most members of the genus *Dendrocincla*, which are largely unmarked. Most species have creamy, whitish or light brown streaks and tear-shaped spots, but the Olive-backed and Spotted Woodcreepers are unique in sharing triangular spots on the back and chest. Barring is usually restricted to the belly, and even then is obvious only on species of *Dendrocolaptes*, *Hylexetastes* and *Xiphocolaptes*. The degree of barring reaches its extreme in the Northern and Amazonian Barred Woodcreepers, each being extensively barred above and below. A feature present only on the Olivaceous and Wedge-billed Woodcreepers is a conspicuous wingbar running obliquely across all but the outer remiges. As this bar is formed by pale spots on the inner webs of the remiges, it is seen most easily from below on the spread wing, a vantage seldom attainable with living woodcreepers in the field; the wingbar is mostly concealed when the wings are folded.

Some adaptations designed to resist feather wear or degradation in moist environments seem apparent in the plumage. On many woodcreepers, the tips of the remiges, especially those of the outermost primaries that are exposed on the folded wing, are much darker, containing more melanin than is present in the rest of those feathers. There is a slight tendency towards darker coloration in birds occupying regions of higher relative humidity, in accordance with Gloger's rule, but the pattern is subtle, as has been discussed for some *Dendrocolaptes* woodcreepers. Species that occupy open habitats may be dramatically countershaded, dark above and light below, in comparison with those that favour

The scansorial lifestyle of woodcreepers has led to a suite of unique adaptations, most obvious of which are strong feet that bear sharp, hook-like claws for gripping bark, and the lengthened, toughened and curved spines of the tail feathers, which function as a prop. This prop is so important that if woodcreepers lose their tails they have great difficulty climbing. Both these features can be seen in this **Spot-throated Woodcreeper**, one of two species in the genus *Deconychura*. Both have slender bodies and fine straight bills and are reclusive inhabitants of humid forest, but, despite their apparent similarity, it is possible that they occupy separate clades intermediate between *Dendrocincla* and *Glyphorhynchus*.

[*Deconychura stictolaema clarior*, Posé, French Guiana. Photo: David Massemin/Bios]

The **Wedge-billed Woodcreeper** is one of the most widespread species in the family, being a familiar species from Mexico to eastern Brazil. Little larger than a treecreeper (Certhiidae), it is the smallest woodcreeper, and the only one with an obviously upturned bill, a feature typical of gleaners. Although it has the highly developed tail spines characteristic of woodcreepers, it retains one feature thought to be ancestral: a wingstripe on the base of the remiges reminiscent of many species of ovenbird (Furnariidae).

[*Glyphorhynchus spirurus subrufescens*,  
River Anchicaya,  
near Buenaventura,  
Colombia.

the forest interior. The Narrow-billed Woodcreeper, for instance, occurs in open country and has predominantly white underparts. Other examples of dendrocolaptids with relatively pale plumage are the Scimitar-billed Woodcreeper, the Moustached Woodcreeper, and some subspecies of the Red-billed Scythebill that inhabit predominantly open or semi-open landscapes.

Limited data, for a few species, suggest that woodcreepers undergo a single, annual moult that lasts from four to six months. The wings and the tail are typically moulted simultaneously, although wing moult may start first. As with most bird species, the remiges are replaced in sequence from the innermost primary outwards and from the outermost secondary inwards; the rectrices are moulted outwards from the innermost pair. Moult usually follows immediately after the breeding season, but for at least a few dendrocolaptids, such as the Northern Barred and Streak-headed Woodcreepers, moult and breeding may overlap. The Amazonian Barred Woodcreeper's cycle of breeding and moult is believed to extend over a period of nine to ten months, while a female Streak-headed Woodcreeper possessing a brood patch was in the early stages of moult. It is thus possible that some species begin the moult process before their young leave the nest. Overlap of moult and breeding may be an adaptation either for a long moult cycle to be completed before mating and singing resume in the next breeding season or, alternatively, to allow the completion of both during a flush of prey abundance.

The most distinctive aspects of woodcreeper morphology are manifest in their adaptations for tree-climbing, or "hitching". To some extent, these adaptations are shared with other tree-climbing birds, such as the woodpeckers, a few genera of ovenbirds (e.g. *Margarornis* and *Pygarrhichas*) and treecreepers (Certhiidae), but with important differences and modifications. All woodcreepers are able to hitch up vertical trunks by flexing their legs and hopping forwards; the long and spiky tail holds them in place when they stop. Rigid shafts of the tail feathers facilitate these tail-braced movements and postures. Among all tree-climbing birds, strengthening of the tail shafts appears to be best developed in woodcreepers, which tend to have proportionately longer rectrices. Unlike other birds that use the tail as a brace, however, the woodcreepers' denuded, spiny rectrix tips are curved downwards like claws, allowing them to contact the substrate at a right angle. The stiffened rectrices with rigid, spiny tips enable the tail to support most of the bird's weight. Woodcreepers that have lost the tail have great difficulty in climbing.

Several characteristics of the foot and leg are adapted for climbing trees. Woodcreepers have an anisodactyl foot, with three toes pointing forwards and one toe backwards, an arrangement typical of all passerines. Their feet differ from those of most passerines, however, in having the outer and middle toes united for much of their length, and of similar lengths, both being much longer than the inner toe. The hallux is reduced. The claws of the

Within this relatively unspectacular family, the **Long-billed Woodcreeper** is perhaps the most striking species. It is a strange and charismatic creature that occurs in riverine habitats, swamps and flooded forests throughout much of Amazonia. Its bill, which accounts for more than a quarter of its total length, is used for probing into bromeliads and other epiphytes. The species is also notable for its loud and distinctive song, a series of mournful whistles, easily imitated by humans. Even poor imitations usually elicit a response: territorial individuals approach aggressively, growling excitedly and peering about in search of their imagined competitor.

[*Nasica longirostris*, Esmeralda, Amazonas, Venezuela.  
Photo: Bruno Walther]

three front toes are strongly curved, aiding in clinging, whereas the claw of the hallux is long and often pressed hard against the substrate, providing support. Strong thighs dominated by strengthened flexor muscles, which have developed at the expense of extensor muscles, provide the power for climbing up trunks. Extensive ossification of the leg tendons appears to be an adaptation for resisting stress on the toes and ankle flexors while clinging to trees. Ossification of the tendons in the legs is reduced, or is more individually variable, only in those woodcreepers that do not rely exclusively on tree-climbing for foraging; these include the Tawny-winged Woodcreeper (*Dendrocincla anabatina*) and, probably, other species in the genus *Dendrocincla*. Elaborate tree-climbing adaptations allow dendrocolaptids to exploit several ecological niches, but they also greatly restrict a woodcreeper's ability to use other modes of locomotion or the wide variety of perches available to most passerines.

Most woodcreepers are exclusively arboreal, moving between trees with a strong, slightly undulating flight. As may be expected for birds that often fly only short distances and glide frequently, dendrocolaptids have broad wings with rounded tips. Many species, especially those that forage in association with army-ant swarms (see Food and Feeding), often approach or briefly land on the ground. Members of the genus *Xiphocolaptes* seem to spend more time on the ground than do the majority of woodcreepers, with the Great Rufous Woodcreeper being the most terrestrial. Only the Scimitar-billed Woodcreeper, with its relatively short tail and unusual hind-limb musculature, seems suited to a terrestrial lifestyle. This species runs on the ground with little difficulty.

The bill is by far the most adaptively variable feature of dendrocolaptid morphology. Its size and shape are closely correlated with foraging behaviour and have evolved around four major themes: gleaner; flycatcher; probing; and chiseller. The Wedge-billed Woodcreeper is the only member of the family that has the bill of a typical gleaner. The Olivaceous and Spot-throated Woodcreepers glean with a short, pointed bill, but they also sally after prey flushed from trunks, so the bill is somewhat broadened at the base. The Long-tailed Woodcreeper and species in the genera *Dendrocincla* and *Dendrocolaptes* have a relatively short and straight, flycatcher-like bill, characterized by a weak hook at the

tip of the maxilla. That of *Dendrocolaptes*, in particular, recalls the bill of tyrant-flycatchers (Tyrannidae), being relatively short, broad-based, flattened dorsoventrally, and hooked at the tip. These species frequently sally out for prey on the ground, trunks or foliage, or in the air, catching large arthropods and even small vertebrates (see Food and Feeding). Bills used for probing are the most variable in length and shape, being narrower and more delicate compared with other types; in addition, they tend to be compressed laterally, instead of dorsoventrally. In the case of some species, the bill is extraordinarily long and either straight, like that of the Long-billed Woodcreeper, or extremely decurved, like those of the scythebills. Dendrocolaptids possessing a probing bill explore a variety of cavities in tree and fern trunks, dead-leaf clusters, bamboo stems and epiphytes. Willis noted that species with a straight bill tend to probe from a lateral position, whereas those with a decurved bill probe from a vertical position. Many species with a probing bill also glean insects from bark or occasionally sally out after flushed prey.

Bills used for chiselling, seen on members of the genera *Hylexetastes* and *Xiphocolaptes*, are a variation of those used for probing. Such bills are laterally compressed and relatively deep and heavy. Species having this type of bill capture large prey on trunks, or tear apart decaying material accumulated on branch forks and in epiphytes. The bill of *Hylexetastes* is similar to that of *Xiphocolaptes*, but is shorter. The two *Hylexetastes* woodcreepers are more generalist foragers, at times sallying out for prey in the manner of many woodcreepers that have a flycatcher-like bill.

## Habitat

Woodcreepers inhabit chiefly forest or woodland, from tropical rainforest in the lowlands to stunted cloudforest near the timberline, but a few species occur in savanna or other semi-open habitats. Most species are restricted to tropical evergreen forest, but some are plentiful in semi-deciduous woodland and gallery forest in drier regions. A small number occur in pine-oak (*Pinus-Quercus*) woodland and pine forest in the mountains of Central America, and others frequent montane evergreen forest or

So many morphological characters of the **Scimitar-billed Woodcreeper** are presumed to be ancestral that some taxonomists consider this species basal to all woodcreepers.

Not only is its syrinx structure unique, but it is also one of very few woodcreepers not infested by feather mites of the genus *Platyacarus*. With its relatively short tail and unusual hind-limb musculature, it also seems to be the only member of the family suited to a terrestrial lifestyle. Indeed, while it is often found in trees, it regularly drops to the ground and runs with little difficulty. It occurs in the Chaco region of eastern Bolivia, western Paraguay and northern Argentina, where it frequents arid scrub, dry forests and savanna. In common with several other species of woodcreeper that live in drier or more open habitats; its plumage is relatively pale and countershaded. This is presumably due to a combination of bleaching, camouflage and the need to strengthen plumage with melanin in more humid environments.

[*Drymornis bridgesii*,  
El Palmar National Park,  
Argentina.

Photo: Günter Ziesler]

cloudforest in the Andes and other mountain ranges. The *Polylepis* woodlands of the high Andes and the temperate forests of southern South America are perhaps the only forested habitats in the Neotropics that are devoid of woodcreepers. As a result of their sedentary nature and their aversion to crossing large unforested gaps, few dendrocolaptid species inhabit offshore islands.

Most woodcreepers are found in lowland forest, but a few species occupy higher elevations. The vast majority of this family's members are restricted to tropical lowlands from sea-level to elevations mostly below 1000 m, with some species occurring sparingly to 1500 m. Above this elevation, the Tyrannine (*Dendrocincla tyrannina*), Olive-backed and Montane Woodcreepers and the Greater Scythebill are among the few species that are largely confined to Andean cloudforest, mostly at elevations ranging from 1500 m up to 3000 m but, depending on the species, locally down to 700 m or up to 3400 m. In the mountains of Central America, the White-striped and Spot-crowned Woodcreepers likewise frequent cloudforest, pine-oak woodland and pine-fir (*Pinus-Abies*) forest, ascending locally to 3600 m. Most lowland and montane dendrocolaptids occur exclusively within their preferred elevations, but a few widely distributed species occur from lowland rainforest up to montane cloudforest. The Strong-billed and Black-banded Woodcreepers are the best examples of this pattern, with some populations of each having strictly montane distributions and others being restricted to the Amazonian lowlands.

The rainforests of the Amazonian lowlands are without doubt the centre of woodcreeper distribution, with many localities harbouring in excess of 15 species and some supporting more than a third of all woodcreeper species. Maximum diversity is reached at sites where upland (*terra firme*) forest and seasonally flooded (*várzea* and *igapó*) forests exist in close proximity. Most woodcreepers occur in the upland forest, but a few, such as the Long-billed, Striped and Zimmer's Woodcreepers, are largely restricted to seasonally flooded and river-edge forests. Within each of these habitats, woodcreepers are often segregated by micro-

habitat, often through the use of different strata or unique substrates. The scythebills' specialization on bamboo thickets is a striking example: at some Amazonian sites, both the Red-billed and the Curve-billed Scythebills are to a great extent confined to dense stands of bamboo, mostly *Guadua*.

Different species of woodcreeper join different types of foraging flocks. Some associate primarily with mixed-species flocks that travel rapidly through the forest, while others join aggregations of birds that forage in association with swarming army ants. Species in the genera *Xiphorhynchus* and *Lepidocolaptes* often forage with mixed flocks in which most species frequent trunks and branches in the understorey and mid-levels of the forest, but a few, such as the Lineated Woodcreeper, instead seek food in the forest canopy. By contrast, woodcreepers that forage in association with army-ant swarms, examples of which include the White-chinned, Black-banded and Red-billed Woodcreepers, often perch on trunks within a few metres of the ground while awaiting prey, which they capture on or near the ground. Differences among the members of the family in the use of habitat are discussed in greater detail below (see Food and Feeding).

Away from Amazonia, the number of dendrocolaptid species co-existing at a given site drops significantly. In the Atlantic Forest of south-eastern Brazil, for example, no more than eight species are found in sympatry. Likewise, whereas 15-19 woodcreeper species co-exist at many Amazonian sites, only nine have been recorded at the well-worked La Selva Biological Station, in the lowlands of Costa Rica; indeed, only 19 species occur in all of Central America. Regional diversity may be higher where elevational gradients are pronounced because some woodcreeper species show a pattern of altitudinal replacement, but at a local level species diversity decreases rapidly at higher elevations.

Most woodcreepers are relatively specialized in their micro-habitat use, with the majority frequenting the understorey and mid-levels of the forest interior. A significant percentage are more flexible in that they regularly frequent forest edge or enter older second growth when it regains the character of mature forest. Far fewer dendrocolaptids inhabit younger second growth, planta-

**The Strong-billed Woodcreeper** is the most widespread and morphologically variable member of the genus *Xiphocolaptes*.

Throughout its vast range, 25 subspecies are currently recognized. All four members of this genus have bulky bodies, relatively short tails, and long, massive, laterally compressed bills. In terms of morphology, they seem to form a sister-group to *Hylexetastes*, members of which tend to have plainer plumage, stubbier bills and different vocalizations. Members of *Xiphocolaptes* occur from Mexico south to the Chaco region of Bolivia, Paraguay and Argentina, and occupy a broad spectrum of wooded habitats, including humid cloudforest, lowland rainforest, and the semi-arid woodlands.

[*Xiphocolaptes promeropirhynchus emigrans*, Chan Chich, Belize. Photo: Joe Fuhrman]

The genus *Dendrocolaptes* forms a discrete group of woodcreepers apparently allied to *Xiphocolaptes* and *Hylexetastes*.

The members of this genus tend to have large bodies and wide-based bills that are less bulky than those of their nearest relatives. The ventral plumage is usually strongly barred and the throat is often pale, features that are clearly seen on this **Planalto Woodcreeper**. This species occurs in the Atlantic forests of east and south Brazil, east Paraguay and north-east Argentina, where it replaces its sister-species, the Black-banded Woodcreeper (*D. picumnus*) of Amazonia.

[*Dendrocolaptes platyrostris platyrostris*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

tions, selectively logged forest or isolated forest fragments, and, in most cases, these are the very species that live in more open habitats.

In addition to the four species characteristic of semi-open habitats (see below), there are a few woodcreepers that, despite requiring at least patches of mature forest nearby, seem to be able to exploit a variety of forest types. Near the northern limit of the family's distribution, the Ivory-billed Woodcreeper occurs in a variety of lowland, montane, deciduous, pine-oak and secondary forests, from sea-level to about 2500 m. Willis even speculated that this species' behavioural plasticity may give it an advantage over more specialized woodcreepers in the variable climate typical of northern latitudes. It may be a similar plasticity that has allowed the Olivaceous Woodcreeper to become the most widespread member of the family, with a range extending from near the northern edge of woodcreeper distribution, in western Mexico, to near the southern limit, in northern Argentina, and also from sea-level to nearly 2300 m. The Olivaceous Woodcreeper occurs in lowland rainforest in Amazonia and along the Atlantic coast of Brazil, in deciduous woodland on the Yucatán Peninsula and in the *caatinga* of north-eastern Brazil, and in montane forest in Central America, the Andes, the coastal ranges of Venezuela and the various ranges of the Brazilian Atlantic Forest. It is also one of few dendrocolaptids that is present on the offshore island of Tobago, although, surprisingly, it is absent from Trinidad.

Only a few woodcreepers occupy predominantly non-forested habitats. The Narrow-billed Woodcreeper is widespread in both savanna (*cerrado*) and Chaco vegetation in central South America, and, more locally, elsewhere on the continent. It also occurs in gallery and dry forests and can even be found in gardens and city parks. Even more plastic in its habitat preferences is the Straight-billed Woodcreeper. This species is largely restricted to coastal mangroves in some parts of its range, but elsewhere it frequents arid scrub, wooded savanna, gallery forest, or seasonally flooded forest. It is equally at home near humans, frequenting plantations, scattered trees associated with agricultural lands, and even clumps of trees in and around some Amazonian cities. The only wooded situation that it avoids is the interior of mature forest. The Streak-headed Woodcreeper fills a similar niche in Central America. It shows a comparable variety of habitat preferences, and appears to be equally comfortable in the proximity of humans. The Scimitar-billed Woodcreeper occurs in arid scrub, savanna, and the Chaco woodlands of southern South America.

Finally, there are four dendrocolaptids that can be found in semi-open woodland. The Great Rufous and Moustached Woodcreepers, in addition to some populations of the Olivaceous Woodcreeper and the Red-billed Scythebill, occur primarily in semi-deciduous and deciduous woodlands, habitats that may be transformed seasonally into semi-open environments.

### General Habits

Woodcreepers are among the most characteristic avian inhabitants of Neotropical lowland forests. Their conspicuous habit of creeping, or "hitching", up trees gives the group its name. This behaviour converges with that of the generally smaller but morphologically similar treecreepers of the families Certhiidae and Climacteridae, which together occupy much of the rest of the world. In each group, the birds climb up tree trunks and branches by grasping the bark with their strong feet and long claws, and using the spine-tipped tail as a prop. Woodcreepers move with short hops, those of some species being so rapid that motion appears smooth. Although they occasionally back down trunks, especially when descending into nesting or roosting cavities, or when foraging in association with ant swarms, they typically move upwards and outwards, using a direct or spiral route. Trunk-foraging woodcreepers begin near the bottom of their preferred stratum, creep to the top of this level, and then fly to the base of the next tree to repeat the process. Most species prefer vertical trunks, but others select horizontal limbs in the canopy, and a few seem to specialize in creeping along the undersides of branches. Only a few species, particularly those frequenting open situations, regu-

larly descend to forage on the ground (see Food and Feeding). The flight of most large woodcreepers is strong but somewhat undulating, with rapid flaps interspersed with glides on outstretched wings and spread tail. Smaller species have a more direct and darting flight.

Woodcreepers are generally encountered singly or in pairs, but many species join the mixed-species flocks that are ubiquitous in the lowland forests they frequent. Woodcreepers usually attend flocks of insectivores, rather than those of tanagers (Thraupidae) and other frugivores. Most species associate with understory flocks containing *Myrmotherula* antwrens and, especially, *Thamnomanes* antshrikes. A few species, most notably the Lineated Woodcreeper, associate with canopy flocks led by greenlets (*Hylophilus*) or other canopy-dwelling insectivores. Groups of woodcreepers consisting of more than a single pair are uncommon in most species, and in most instances these groups represent families, with one or both parents tending dependent young. In the case of *Dendrocincla*, only one parent raises the young (see Breeding), so that groups of multiple individuals probably represent either a mother and her offspring or aggregations of wandering immatures. By contrast, the larger woodcreepers of the genera *Dendrocolaptes*, *Hylexetastes* and, presumably, *Xiphocolaptes* remain paired throughout the year, and the young of some species may not become independent until the beginning of the year after hatching; thus, when two individuals of a species are seen together, they usually represent members of a pair, and small groups are likely to be family parties.

The aggregations of woodcreepers that gather, sometimes in fairly large numbers, over swarms of army ants are anomalous for these typically solitary birds. Ant swarms are often attended by three or fewer Plain-brown Woodcreepers, although it is not unusual for four or five individuals to be present together, and in Trinidad, in the absence of competing thamnophilid antbirds, up to twelve individuals of this species have been found at the same swarm. Similarly, seven or eight White-chinned Woodcreepers have been noted at ant swarms in south-eastern Peru.

*Taxonomic confusion is notable in the Dendrocolaptidae, a situation best exemplified by Xiphorhynchus. This, the largest genus in the family, covers a broad geographical distribution, as well as a diverse range of body sizes and ecological adaptations. One superspecies group is centred around the Ocellated Woodcreeper (X. ocellatus). Although this group is often considered to consist of two species, the Ocellated and Chestnut-rumped Woodcreepers, recently published mtDNA data support treatment involving three separate species, with the recognition of Tschudi's Woodcreeper (X. chunchotambo).*

[*Xiphorhynchus pardalotus*, Guyana.

Photo: Doug Wechsler/VIREO]

The genus *Lepidocolaptes* is a well-defined group of woodcreepers, all of which are relatively small, with a slender decurved bill and a propensity to follow mixed-species flocks. As it follows these flocks, the **Spot-crowned Woodcreeper** hitches up trunks, checking for insect prey amongst the mosses and lichens of its cloudforest home. As this photograph reveals, the legs of woodcreepers are usually splayed outward, in a posture reminiscent of woodpeckers (*Picidae*). It would appear that this orientation of the legs, in conjunction with the stabilizing prop of the tail, allows for more efficient gripping and climbing. The photograph shows another recurrent theme: in many woodcreepers, especially those of humid environments, the tips of the flight-feathers are contrastingly dark. This is the result of high densities of melanin, a compound that strengthens feathers and protects them against excessive wear. The distribution of melanin in the remiges of woodcreepers is likely to be an adaptation to counter feather damage.

[*Lepidocolaptes affinis neglectus*,

The taxonomic sequence of woodcreepers terminates with the *Campylorhamphus* scythebills, an assemblage of five species easily differentiated from most other members of the family by virtue of their amazingly long and downcurved bills. The scythebills use this most distinctive feature to probe inside clusters of vegetation, moss and bromeliads, in search of invertebrate prey. The **Black-billed Scythebill** is the only member of the genus that occurs in the Atlantic Forests of south-eastern Brazil.

[*Campylorhamphus* falcularius, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Although not particularly secretive, many woodcreepers are nonetheless shy. Most move rapidly and continuously, making them difficult to observe. Only rarely do trunk-foraging woodcreepers remain motionless for more than a few seconds. By contrast, those that forage over ant swarms are more sedate, primarily because they must wait to spot prey flushed by the ants. Accordingly, a disproportionate amount of what is known of the behaviour of woodcreepers pertains to birds foraging in association with ants. At the first sign of danger, woodcreepers hide on the rear surface of large trunks while tentatively peering around to investigate the situation. Many are difficult to approach and to study at close quarters, but some become accustomed to the presence of an observer, especially during extended periods of observation while they forage over army ants.

Roosting behaviour has been studied for only a few dendrocolaptids, in Costa Rica by A. F. Skutch, and in eastern Amazonia by Y. Oniki. Woodcreepers roost solitarily, in cavities similar to the ones used for nesting (see Breeding). Natural cavities are used more often than are old woodpecker holes, possibly because they are less conspicuous. The young do not return to the natal nest after fledging, but instead they seek new sites for roosting. Although documented roost-sites have been in cavities relatively close to the ground, this may reflect ease of observation as much as it does availability of suitable cavities or particular preferences. A captive Straight-billed Woodcreeper roosted in an upright position, with its head tucked into its back feathers. This posture is probably the typical one adopted by roosting woodcreepers.

Maintenance behaviour among the members of this family is poorly known, with most information being only anecdotal. Various woodcreepers scratch the head by the indirect method, reaching over a wing with one foot while gripping the substrate with the other. In addition, many dendrocolaptids have been observed to perform "anting" behaviour, in which they rub small, presumably noxious items on the wing or tail feathers; sometimes, the items are then eaten. Anting behaviour is often thought to be a means of removing ectoparasites of the plumage or skin, but Willis

suggested that it might serve to wipe distasteful secretions from prey, and H. Sick pointed out that formic acid released during anting might be a physiological stimulant.

Regardless of the true function of anting, and despite a dearth of knowledge of the natural history of the Dendrocolaptidae, woodcreeper parasites are fairly well studied. G. Bennett and colleagues have studied blood parasites in many woodcreeper species. Likewise, R. Price and D. Clayton reviewed an array of feather lice, chiefly of the genus *Rallicola*, that are known from woodcreeper hosts. Moreover, L. Kudon described a new genus of feather mites, *Platyacarus*, that is specific to woodcreepers, and detailed host-parasite relationships for many new species in this genus. Within the family, the absence of *Platyacarus* mites on the Scimitar-billed Woodcreeper provides support for the ancestral position of the genus *Drymornis*, for these mites infest at least some members of almost all other dendrocolaptid genera. Finally, M. Marini and D. Couto correlated ecological parameters and ectoparasite infestation for several woodcreepers from central Brazil.

Some woodcreepers are remarkably aggressive towards conspecifics and even towards other woodcreepers. During his studies of ant-followers, Willis documented numerous instances of both intraspecific and interspecific aggression among dendrocolaptids, while N. Pierpont studied interspecific interactions in a guild of woodcreepers occurring in Peru. Not surprisingly, both found that larger species are generally dominant, but some highly aggressive *Xiphorhynchus* species periodically attack the larger, less agile and possibly somewhat more docile species in the genus *Dendrocolaptes*. The Buff-throated, Black-striped and Tschudi's Woodcreepers seem to be especially aggressive. Pierpont speculated that the aggressive nature of Tschudi's Woodcreeper may be necessary for it to defend territories against the larger Elegant Woodcreeper, which generally dominates it, even forcing it into marginal habitats.

Most woodcreepers are highly territorial, but "territorial" defence is not necessarily of the same kind as that demonstrated by passerines of temperate regions. For example, among species

Woodcreepers, almost by definition, are fundamentally arboreal. As a corollary of their association with trees, they are virtually confined to forest or woodland, just about wherever these habitats occur in Central and South America. Although some forms are adapted to semi-arid or montane habitats, woodcreepers reach their highest diversity in the extensive lowland rainforests of Amazonia. Here, species such as the **Wedge-billed Woodcreeper** thrive, and various localities hold more than a third of all woodcreeper species.

of understory-dwelling *Xiphorhynchus* studied by Pierpont in south-eastern Peru, territorial defence manifests itself in the eviction of intruders from understory flocks. In the case of the Elegant Woodcreeper, the dominant species in this guild, pairs excluded intruders from two understory flocks, but they allowed intrusion into the area, not only by other *Xiphorhynchus*, but also by conspecifics, provided that these intruders did not attempt to join their flocks. Thus, aggression and "territory" defence are largely limited to the immediate proximity of these flocks. One can only speculate why many woodcreepers sing only briefly, at dawn and dusk, from favoured perches near their nests or roost-sites. Song does appear to be seasonal for at least some species, their dawn bouts of singing being longer during the breeding season but quite brief at other times. Perhaps the availability of cavities used for roosting and, especially, for nesting is a limiting factor, much as are foraging opportunities in mixed-species flocks. If so, woodcreepers may concentrate their energy on defence of niche parameters that are most limiting. Future investigation of this atypical singing behaviour should provide an insight into the importance of territoriality in the family Dendrocolaptidae.

## Voice

Most woodcreeper songs are neither complex nor musical, but they are among the most characteristic components of dawn and dusk choruses in Neotropical forests. Woodcreeper songs are primarily simple rattles or trills, those of a few species comprising clear whistles. Some species emit rapid and repetitive renditions of a single note. Others have songs that take on the character of a whinny or a laugh by initially ascending and then descending, before slowing at the end. The song of the Long-billed Woodcreeper is atypical, being a simple series of three to five drawn-out whistles each described as "whoooOOOooo", "twooooooóoo" or "wheeeeéer". Only a few dendrocolaptids regularly utter more complex vocalizations, with the song of the Brown-billed Scythebill (*Campylorhamphus pusillus*) perhaps representing the pinnacle of complexity in the vocal capacities of the family: a soft, twittering trill in the background is combined with a series of loud, quavering whistles in the foreground,

yielding a song described as "wheéwhipwhipwhipawéé, at-t-t-t-weeawééawéé" or "twe-weo-WEO-weo-weo-we-we-we-we". The Scimitar-billed Woodcreeper is likewise atypical for a woodcreeper, because the loud, descending jumbles of notes that represent its song are often given in a duet.

The frequency range of woodcreeper songs is neither particularly high nor particularly low. M. Palacios and P. Tubaro documented the range as being 840 Hz to 8830 Hz for the songs of all but a few species, and they found an inverse correlation between song frequency and both body mass and bill length, the latter even after removing the effects of body size. Therefore, songs with lower frequencies are given not only by the larger species, but also by those with the longest bills. These authors suggested that, in addition to the well-known trend for larger birds to have deeper-voiced songs, the increased length of the vocal tract corresponding with a longer bill may result in resonating properties that affect song frequency. The correlation was complicated, however, by a tendency for species living in open habitats, such as wooded savanna, to have higher-frequency songs than those occupying forested habitats. The correlation of bill length and song frequency was therefore significant only when two open-country species, the Narrow-billed and Scimitar-billed Woodcreepers, were excluded from analyses.

Woodcreepers stand out among Neotropical birds for their tendency to sing during twilight hours. Apart from a few crepuscular species noted for singing in the pre-dawn darkness, such as forest-falcons (*Micrastur*) and potoos (*Nyctibius*), woodcreepers are among the first birds to sing at dawn and the last to sing at dusk. Many dendrocolaptids begin singing at the first hint of light in the sky, and their dawn chorus is over even before sunlight hits the forest canopy. Several members of the family, particularly those in the genera *Dendrocincla*, *Dendrexetastes*, *Hylexetastes*, *Xiphocolaptes* and *Dendrocolaptes*, and many *Xiphorhynchus* species, sing for no more than a few minutes in the near-darkness of pre-dawn, after which they begin their daily foraging. Many woodcreepers seldom sing during the day, so forging an association between voice and visual characters is extremely difficult, making the field identification of many woodcreepers a challenge. Most species that sing through the day do so intermittently, and, in many cases, those species that

sing during the daytime do not sing extensively at dawn. Regardless of time of day, the Olivaceous Woodcreeper typically sings intermittently, and, despite a lack of quantitative data, it seems hardly more likely to sing at dawn than to sing after sunrise. Unlike many others in the family, the Olivaceous Woodcreeper rarely delivers more than one or two songs at a time or from the same perch. Instead, this woodcreeper forages actively and sings rarely, so singing individuals are often difficult to follow. Some *Lepidocolaptes* and several of the smaller *Xiphorhynchus* species likewise sing intermittently during the day, but generally not for extended periods at dawn or dusk.

Willis found that some woodcreepers sing at dawn and dusk from perches near the centre of their territory, often near a roost-site. In these instances, song may function as a means of marking a bird's nesting or roosting territory, and, in the absence of other birds invading this territory, little singing is necessary. Territorial interactions are often accompanied by song, but Pierpont found that various species of *Xiphorhynchus* evicted intruders from mixed-species flocks, rather than from a territory itself (see General Habits). In such cases, constant singing of the kind used by birds defending a patch of suitable habitat may be unnecessary.

Despite the fact that their songs are given largely at dawn and dusk, woodcreepers are not necessarily quiet during the day, because most utter a variety of calls. The better-known species, such as the Buff-throated Woodcreeper and the closely related Cocoa Woodcreeper, regularly utter three or four different calls, and occasionally several others. Pair-members of the Buff-throated Woodcreeper are regularly encountered while foraging together, often among mixed-species flocks. Although these birds rarely sing during the daytime, mates appear to communicate with each other by using characteristic "long calls" that are given intermittently throughout the day, in all months of the year. It is possible that reports of singing by both sexes of some woodcreepers, including the Buff-throated, in fact involve individuals emitting long calls rather than true songs, which appear

to be given only by the males, and primarily during the breeding season. The most common call of the Buff-throated Woodcreeper is a descending series of five to seven loud, sometimes paired, whistles and has been described as "wheer, wheer, whip-whip-wip-wip" or "fee-a-wip, fee-a-wip, wip-wip". This species also utters, in a variety of contexts, especially when going to roost, a piercing whistle or "short call" described as sounding like "pyeeeu" or "stool".

Homologues of both the long call and the short call are given not only by other *Xiphorhynchus* species, but also by the Plain-brown Woodcreeper of the genus *Dendrocincla*. The diverse repertoire of the Plain-brown Woodcreeper includes both a short, descending trill, which many authors consider to be the song, and a long, incessant sputtering that may last for several minutes at a time, which many regard as a call. The true function of these vocalizations remains unclear, but the conditions under which the sputtering "trill" is given, generally at dawn, suggest that it represents the song of the species. By contrast, the short trill is given throughout the day, and apparently by immatures and adults of both sexes.

Considering its infrequent nature, the role of song in maintaining pair-bonds is uncertain. Most woodcreepers appear to be monogamous, and many remain paired throughout the year, but this is not true of all species. All members of the genus *Dendrocincla* for which data are available appear to form only brief pair-bonds, but the degree to which this is true of other woodcreeper species is unclear (see Breeding). The Tyrannine Woodcreeper has a remarkably loud song that it delivers for several hours daily through the breeding season, usually from the same perches on exposed ridges. Although apparently territorial when singing, males do not react to tape playback outside their normal hours of singing. On the basis of these findings, from a study in the Colombian Andes, Willis and Oniki suggested that these birds may mate on "exploded", or dispersed, leks that have come about as a result of the difficulty of finding mates in the sparsely populated and densely vegetated environment frequented

The fact that one species of woodcreeper is able to co-exist with several others is achieved through resource partitioning.

The **White-throated Woodcreeper**, for example, is usually seen foraging in the lower strata of forest (often 5-8 m up), where it favours thick, mossy trunks averaging over 75 cm in diameter. This species shares the Atlantic Forest with several other woodcreepers, most of which prefer to forage on slimmer trunks, or at greater heights above the ground. These differences in foraging technique, or foraging substrate, help to minimize the direct competition between species for resources.

Rio de Janeiro, Brazil.  
Photo: Edson Endrigo]

The **Buff-throated Woodcreeper** is amongst the commonest birds in a variety of forested habitats across the lowlands of Amazonia. With the use of vision alone, an ornithologist working in the region is likely to see this species once every day or two. If the same ornithologist is familiar with its voice, however, it will be heard dozens of times during the same period. The degree of this disparity relates to a variety of phenomena, not least the difficulty of seeing wildlife in the rainforest. Aural cues are particularly important in such a complex environment, and the Buff-throated Woodcreeper assists by periodically emitting loud vocalizations throughout the day. The reason for the abundance of this species in Amazonia is perhaps related to its generalist foraging strategy and aggressive nature. It climbs trunks of various different sizes, as seen here, and at various different levels above the ground, from human head height up into the canopy. It gleans on bare trunks, but more commonly it probes or rummages amongst clusters of dead leaves or, less often, vines or epiphytes.

Members of the genus *Dendrocincla* are amongst the woodcreepers least inclined to forage by climbing trees. They live in humid forests from Mexico to Argentina. The **Ruddy Woodcreeper** is one of several species in the genus that are regularly, or indeed almost always, found in association with army ants, swarms of which they follow through the understorey, perching on low trunks and sallying after flushed prey. On occasion, they may even perch on a horizontal branch or alight briefly on the ground.

by the species (see Breeding). Continuous singing over a protracted period is also typical of the Cocoa Woodcreeper, another dendrocolaptid that is believed not to form extended pair-bonds. This scant evidence suggests that the frequency with which songs are given and the importance of the song in mate attraction are inversely proportional to the duration of the pair-bond.

Woodcreeper songs contradict the long-standing belief that suboscine songs are highly stereotyped and geographically invariable. Recent work has documented a higher degree of individual variation in woodcreeper song than had ever been suspected. Moreover, in addition to the variations on a theme resulting from individual and micro-geographical differences, the songs of geographically distant populations of what are now recognized as the same species may show remarkable differences, or variations on different themes.

Indeed, marked geographical variation appears to be the rule, rather than the exception, not only in the songs of many woodcreepers but also in those of many other Neotropical suboscines. The significance of this variation, however, remains elusive. Many populations that differ vocally also differ, albeit often subtly, in morphology. In a few instances, research has revealed that some vocal differences among populations correspond to the existence of cryptic species, but the extent of geographical variation in suboscine vocalizations is still unknown. Moreover, although a few North American tyrant-flycatchers have innate songs, subsequent studies on bellbirds (*Procnias*) imply that some suboscine songs are learnt. Furthermore, it seems reasonable to believe that even innate vocalizations should vary geographically, because there is no reason why they should differ fundamentally in this respect from other genetically controlled characters such as aspects of plumage or other morphological characters. Interestingly, this does seem to be the case with the very few suboscines in which it has been investigated. Recent studies have revealed that the songs of certain tyrant-flycatchers of the genus *Empidonax*, as well as those of the furnariid Pale-breasted Spinetail (*Synallaxis albenscens*), do exhibit a limited amount of geographical variation.

Geographical variation is marked and easily perceptible in the songs of the Plain-brown, Long-tailed, Olivaceous, Wedge-billed, Northern Barred, Planalto, Ocellated, Buff-throated, Co-

coa, Straight-billed and Lineated Woodcreepers, and in those of both the Curve-billed and the Red-billed Scythebills. The songs of many other dendrocolaptid species vary more subtly. Exceptions seem to be the Cinnamon-throated Woodcreeper (*Dendrexetastes rufigula*) and members of the genera *Hylexetastes* and *Xiphocolaptes*, the songs of which vary minimally over large regions, despite significant variation in plumage. Even interspecific differences are subtle in the last two genera.

Marked geographical variation in the songs of what was until recently recognized as a single species, the "Barred Woodcreeper", provided the first clue that *Dendrocolaptes certhia*, as then constituted, in fact represented more than one allospecies. Three remarkably different song types are known from these birds, the differences representing not variations on a theme but, instead, completely different themes. First, Amazonian populations utter a rapid whinny or laugh, generally consisting of 8-15 simple notes that rise and then fall in pitch. Secondly, barred woodcreepers from Central America and north-western South America deliver a series of usually three to five protracted whistles with a sharply inflected ending. Finally, on the basis of a few recordings made by the late P. Schwartz, birds from the Maracaibo Basin of north-western Venezuela sing a series of protracted whistles on one pitch, followed by the notes degrading into a harsh chatter. C. Marantz and Willis have recently identified a suite of morphological and behavioural characters that correspond with these song differences, and as a result avian taxonomists now recognize two species, the Northern Barred Woodcreeper and the Amazonian Barred Woodcreeper.

Marantz is currently undertaking work aimed at characterizing geographical variation in the songs of the Buff-throated Woodcreeper and its allies, some of which may lead to the recognition of similar cryptic species. In this case, there appear to be three to five distinct song types in the Buff-throated Woodcreeper. Some populations deliver a rapid three-part whinny consisting of an introduction in which the notes increase in frequency and speed, a middle part during which frequency and speed are relatively constant, and a conclusion that descends and slows. Each part is highly variable in length, even within individual birds, and sometimes one of the parts is lacking altogether, so analysis of geographical variation is a challenging task.

The Olivaceous Woodcreeper offers an even greater challenge to scientists. Preliminary studies reveal that it has at least six different song types, which may be broadly classed into two groups: the trills sung by populations in Central America and adjacent South America; and series of clear whistles given by birds in the rest of the South American range. Although all of these populations have been recognized for more than 75 years as belonging to a single species, geographical variation in plumage and songs is so striking that it is possible that what is now recognized as a single species may instead comprise as many as five allospecies.

It seems premature to draw conclusions solely on the basis of geographical patterns in woodcreeper vocalizations. The high degree of individual variation complicates assessment of geographical differences, and the behavioural context of vocalizations is poorly understood. A tendency towards interspecific territoriality adds further confusion, and in no case is there any sound indication of which vocalizations, if any, serve as reproductive isolating mechanisms in Dendrocolaptidae. Some calls of the Buff-throated Woodcreeper vary geographically to a lesser degree than do its songs, a pattern displayed by many oscine passerines, the Song Sparrow (*Melospiza melodia*) being just one example. If these calls are used for species recognition and mate choice, then marked differences in songs may not be a good indication of evolutionary relationships; preliminary genetic data for the Buff-throated Woodcreeper support this scenario. The function of woodcreeper song, therefore, remains a mystery. The limited understanding of the evolutionary relationships within the Dendrocolaptidae, and of the behavioural context and genetic basis of their vocalizations, lends weight to the view that taxonomic changes should await analyses of multiple, independent data sets. These must encompass, in addition to vocalizations, both genetic and morphological characters, including plumage, bare parts and skeletal features.

## Food and Feeding

The name "woodcreeper" is appropriate for all but a few members of the family because most dendrocolaptids spend much of

their time creeping along the trunks and branches of trees and large shrubs. Species in the genera *Xiphorhynchus* and *Lepidocolaptes* seek their food in a manner typical of woodcreepers. With few exceptions, these species forage while creeping up trunks or outwards along major branches. They either glean prey from the bark's surface or probe into crevices, knotholes, vine tangles, moss clumps, or clusters of bromeliads or other epiphytes. There is, however, some degree of specialization with regard to substrate use. The Buff-throated Woodcreeper, for example, probes or rummages through clusters of dead leaves, whereas the Spotted Woodcreeper tends to forage on trunks heavily laden with moss. Other *Xiphorhynchus* species, and some in the genus *Xiphocolaptes*, may specialize on foraging among bromeliads and other epiphytes.

Gleaning and probing of bark, although characteristic of woodcreepers, are not the sole means of obtaining food. Pierpont distinguished two guilds of woodcreepers on the basis of their primary foraging technique, either picking or sallying. Although the species that primarily pick will occasionally sally after flushed prey, and those that sally also regularly pick prey, the two techniques provide a means of partitioning resources behaviourally rather than spatially. These behavioural differences are associated with specific genera. Species that forage principally while climbing trunks, limbs and vines, either by picking items from the surface or by probing into the wood or other substrate, include the members of the genera *Xiphocolaptes*, *Xiphorhynchus* and *Lepidocolaptes*. Woodcreepers in the genera *Glyphorhynchus*, *Nasica*, *Drymornis*, *Dendrexetastes* and *Campylorhamphus* are probably best treated as pickers with specialized types of foraging behaviour or substrates. Sallying is best suited to "sit-and-wait" predators. Among the woodcreepers, this behaviour is most often associated with attendance at swarms of army ants, which are used as "beaters" to flush prey that is easily captured. Sallying is especially well developed in the genera *Dendrocincla*, *Hylexetastes* and *Dendrocolaptes*, which include those species that depend on following ants. The members of *Sittasomus* and *Deconychura* also sally, but these birds follow mixed-species flocks, not ants. Whereas ant-followers spend much of their time perched motionless, waiting for prey to be flushed, the Olivaceous and Long-tailed Woodcreepers hitch up

Several dendrocolaptids tolerate or even prefer open, dry or degraded habitats. The **Streak-headed Woodcreeper**, for example, is most frequently encountered in open woodland, deciduous and gallery forests, wooded savanna, mangroves, xeric scrub, second growth and forest edge. It is less common in the interior of humid evergreen forest, lower montane forest, oak woodland and pine savanna. At some sites it occasionally forages on cactus stalks, and it even occurs in rural areas, where it visits gardens, orchards and scattered trees in farmland.

[*Lepidocolaptes souleyetii* compressus, Quintana Roo, Mexico. Photo: Patricio Robles Gil]

Another species with a clear predilection for drier or marginal habitats is the **Red-billed Scythebill**.

This species inhabits Chaco woodlands and other open, low-stature formations such as deciduous forest, gallery forest, cerrado and caatinga. It is less frequently found in humid evergreen forest, and where it does occur in this habitat it tends to be distributed primarily in marginal or early successional habitat such as seasonally flooded forest (especially várzea), Gynerium cane, and, especially, patches of bamboo.

[*Campylorhamphus trochilirostris lafresnayanus*, Aquidauana, Mato Grosso do Sul, Brazil.  
Photo: Edson Endrigo]

trunks in the typical manner, suggesting that their sallies are directed at prey flushed during the bird's ascent.

Species in both foraging guilds partition food resources by exploiting different micro-habitats and strata. Among the pickers, for example, scythebills frequent bamboo thickets, where the exceptionally long and strongly decurved bill of the genus is well suited to probing stalks in search of arthropods hidden in the hollow interior. The equally long but straight bill of the Long-billed Woodcreeper may likewise facilitate its probing of clusters of bromeliads along horizontal limbs of canopy trees. The massive but somewhat less unusual bill of species in the genera *Xiphocolaptes* and *Hylexetastes* may allow these woodcreepers to exploit resources that are inaccessible to the smaller and weaker-billed species of *Xiphorhynchus*, such as grubs inside decaying wood. Whereas most *Xiphorhynchus* species forage along trunks and large limbs in the understorey and at mid-levels of the forest interior, the Black-striped Woodcreeper forages primarily in the upper strata of the forest, sometimes making forays into the canopy. Several species of the closely related genus *Lepidocolaptes* likewise forage predominantly in the canopy, a habit especially prevalent when *Xiphorhynchus* woodcreepers also occupy the site. Pierpont suggested that the absence of interspecific aggression between the Lineated Woodcreeper, the sole *Lepidocolaptes* that is widespread in the Amazon Basin, and the various species of *Xiphorhynchus* that she studied was the result of habitat-partitioning by strata. Despite overlap with *Xiphorhynchus* species in both substrate use and size of prey taken, the Lineated Woodcreeper avoids contact with these larger birds by foraging in the canopy above them. It is possible that, where they co-exist with *Xiphorhynchus*, the smaller *Lepidocolaptes* may be pushed up into the canopy.

Similar partitioning by strata has been suggested for the two smallest dendrocolaptids. The Wedge-billed Woodcreeper forages primarily by gleaning tiny prey from the surface of large trunks in the understorey. By contrast, the Olivaceous Woodcreeper seeks food largely in the upper levels of the forest, especially at sites

where it co-exists with the Wedge-billed. The degree to which the Olivaceous Woodcreeper is forced into the canopy by the Wedge-billed Woodcreeper remains untested, but the Olivaceous Woodcreeper forages more by sallying than by picking, and the substrate preferences of these two are not nearly so similar as they are for many larger woodcreepers.

In an early study of substrate use in a community of woodcreepers in south-eastern Brazil, M. de L. Brooke demonstrated an even finer partitioning within the trunk-foraging species of the understorey. He found that species differed in the diameter of trunks that they used, in the distance for which they ascended these trunks, and in their tendencies to forage on trunks or on branches.

Despite the morphological uniformity of the woodcreepers (see Morphological Aspects), many localities harbour a variety of species. Five different pickers in the genus *Xiphorhynchus* occupied Pierpont's study site in south-eastern Peru. Some of these are segregated by habitat, but three understorey species occur syntopically, partitioning the site by means of interspecific aggression, rather than by habitat preference, diet or foraging technique. Indeed, Pierpont demonstrated that the Elegant and Tschudi's Woodcreepers both prefer *terra firme* forest and that both used the same techniques to take prey of the same size from the same substrates. In a few instances, individuals of these two species experienced reciprocal turnover of their territories, demonstrating conclusively that the same sites are suitable to both species. Although they both occurred at the same sites, Tschudi's Woodcreepers preferred mixed-species flocks that travelled through the forest at a significantly faster pace than that of flocks attended by Elegant Woodcreepers. The Striped Woodcreeper was the third species found at the site, where it was largely restricted to palm swamps; radio-tracking, however, revealed that this species repeatedly attempted to invade territories of Elegant Woodcreepers in neighbouring *terra firme* forest. Although the Striped Woodcreeper sallied to a greater extent, it likewise took prey of comparable size to that captured by the

This **Great Rufous Woodcreeper** is perching on the trunk of a tall tree in dry forest of the Chaco region. First it preens intently, and then it pauses to peer down, investigating the nature of the disturbance below. In common with other members of its genus, it possesses a stout bill designed for capturing relatively large prey. Being heavy, laterally compressed and relatively deep, this bill is functional as a preening tool, but ideal for chiselling at crevices, hammering at loose bark, and tearing decaying material from forks and epiphytes.

Calo]

Elegant and Tschudi's Woodcreepers and from similar substrates. Pierpont further demonstrated that overlap in diet and substrate use was positively correlated with interspecific territoriality and aggression, meaning that those species most likely to compete over resources were also the most likely to exclude one another by using aggression. Pierpont's work on understory *Xiphorhynchus* woodcreepers provided an important insight into the way in which closely similar species can co-exist, not only by partitioning resources and micro-habitats, but also through interspecific aggression.

A few dendrocolaptids, principally those frequenting open habitats, regularly descend to the ground. The Scimitar-billed Woodcreeper is the family's archetypical ground-forager. Unlike other woodcreepers, this species eschews foraging among mixed-species flocks of arboreal insectivores, instead looking for food on or near the ground in association with terrestrial ovenbirds. Indeed, it is adept at running on flat surfaces through the scattered vegetation of its preferred habitat, but, like other woodcreepers, the Scimitar-billed does investigate fallen logs, branches, bromeliads, and cavities in trees. Most of its prey appears to be taken from the earth's surface, typically by probing in soft soils. The Great Rufous Woodcreeper, which frequents the same open savannas and Chaco woodland as those inhabited by the previous species, also forages terrestrially on occasion. Although it does not spend so much time on the ground as does the Scimitar-billed Woodcreeper, it does descend regularly to rummage through leaf litter, especially in open habitats. When on the ground, the Great Rufous Woodcreeper usually hops rather clumsily, unlike the Scimitar-billed Woodcreeper, which runs about swiftly and seems better adapted for a terrestrial lifestyle.

Rather unexpected was an instance of an Ivory-billed Woodcreeper seen foraging on mudflats exposed when mangroves were cleared. It is possible that most woodcreepers descend to the

ground only rarely because they are awkward on horizontal surfaces, and thus highly vulnerable to predators.

The majority of accumulated knowledge of the foraging behaviour of woodcreepers is based on detailed observations made by Willis and Oniki of birds foraging over ant swarms. Although these authors' findings may be biased slightly with regard to those woodcreepers that do not normally follow ants, the basic foraging dichotomy appears to be stereotyped. Even over ant swarms, sallying species dart after flushed prey, whereas picking species, which forage over ants opportunistically, take prey primarily by gleaning or probing as they hitch up trunks low over the swarm. Woodcreepers that normally forage at mid-levels may descend to levels near the ground to consume flushed prey. By all accounts, the White-chinned Woodcreeper is an obligate ant-follower. The Red-billed, Black-banded, Hoffmann's, Amazonian Barred, Plain-brown, Plain-winged, Tawny-winged and Ruddy Woodcreepers (*Dendrocicla homochroa*) also follow army ants, but none of them exclusively so. The true ant-followers share a similar mode of foraging: they descend to vertical perches near the ground and await flushed prey. When a prey item is spotted, the woodcreeper sallies out to capture it, whether it is on the ground, on a nearby trunk, amid foliage, or in mid-air. Much like picking woodcreepers, ant-followers use interspecific aggression as a means of partitioning foraging opportunities over swarming ants. Larger species, especially the Red-billed and Black-banded Woodcreepers, take the premier positions, low down over the front edge of the swarm. At army-ant swarms in Amazonian Brazil, Willis noted that near Manaus, in the absence of competing antbirds (*Rhegmatorhina*) and bare-eyes (*Phlegopsis*), the relatively small White-chinned Woodcreeper forages on slim trunks near the ground, but near Belém, where large antbirds are present at swarms, it forages higher up and from broader trunks. Willis reported similar exclusion and release for the Plain-brown

In common with most birds, woodcreepers will occasionally bask in sunlight when the opportunity presents itself, as it has to this **Planalto Woodcreeper**. However, seeking food is the favourite pastime of woodcreepers, and because of this they are usually on the move. When foraging, they tend to climb upwards or outwards along trunks or branches, using a direct or spiral route. Much more rarely they move downwards in reverse, especially when entering nesting or roosting cavities, or when foraging in association with ant swarms. In general they move with short hops, sometimes so rapidly that their ascent seems smooth rather than jerky.

Trunk-foraging woodcreepers generally begin near the base of trees. When they reach the top, they convey themselves rapidly on their rounded wings by means of swooping or undulating flight, interspersed with short glides, to the base of the next tree, where the process is repeated.

Little is known about the roosting behaviour of woodcreepers, presumably because they usually spend the night tucked away in the same kind of cavities in which they nest. Most roosts have been found close to the ground, although this probably relates more to the greater ease with which such sites are checked by humans than to any behavioural bias in woodcreepers. Existing reports suggest that natural cavities are used more often than are old woodpecker holes, possibly because they are less conspicuous. Roosting woodcreepers tend to orientate themselves in an upright position, with the belly against the tree, the body feathers fluffed out, and the bill tucked into the mantle plumage. Some small species may roost in shallow nooks or recesses in rotten wood, rather than in deep holes, as this

**Wedge-billed**

**Woodcreeper** attests.

It is not clear whether larger woodcreepers also use the same type of sites, but this seems less likely. It does seem that woodcreepers are faithful to the same roosting sites for prolonged periods:

this Wedge-billed Woodcreeper slept in this position night after night for several months.

Woodcreeper. In Trinidad, with its dearth of ant-followers, the Plain-brown Woodcreeper forages near the ground and in large aggregations, habits that are rare where this species shares swarms with aggressive antbirds and larger woodcreepers. Unlike the White-chinned Woodcreeper, the Plain-brown Woodcreeper restricts its ant-following to swarms that move through its territory, and it often picks prey items near the periphery of the swarm instead of sallying for prey near the centre.

Willis and others have speculated that some dendrocolaptids characteristic of mixed-species flocks may be attracted to the activity of birds following the ants, rather than to the ants themselves and the prey flushed by them. Some of these woodcreepers appear to be unsure how to take advantage of ant swarms, with many species typical of flocks apparently lacking the patience required to forage over ants successfully. These birds spend little time with the ants before departing to seek a mixed-species flock.

Woodcreepers are chiefly insectivorous. In a comprehensive study of the diets of Brazilian birds, O. Schubart and colleagues listed many arthropods as being consumed by woodcreepers. F. Haverschmidt likewise provided orders and families of arthropods found in the stomachs of woodcreepers occurring in Surinam, and, more recently, A. Chapman and K. Rosenberg, O. Rocha and E. Peñaranda, and F. Puebla-Olivares produced detailed analyses of stomach contents for select species. In addition, B. Poulin and colleagues detailed emetic samples vomited from the stomachs of woodcreepers captured in northern Venezuela, and Willis has observed a variety of prey taken by birds of several species foraging over ant swarms. These studies reveal that woodcreepers typically take arthropods and that they occasionally take small vertebrates, and yet, with the exception of prey size, the diet differs little across species.

The most common food items are grasshoppers and crickets (Orthoptera), beetles (Coleoptera), cockroaches (Blattodea), ants (Formicidae), spiders (Araneae) and, in the case of some species, lizards. Woodcreepers take smaller quantities of leafhoppers and cicadas (Homoptera), bugs (Hemiptera), termites (Isoptera), earwigs (Dermaptera), ant-lions (Neuroptera), bees and wasps (Hymenoptera), flies (Diptera), moths (Lepidoptera), caterpillars and other insect larvae, dragonflies (Odonata), centipedes (Chilopoda), millipedes (Diplopoda), scorpions (Scorpiones), pseudoscorpions (Pseudoscorpiones), and even small snails (Mollusca) and crabs (Decapoda). Fruit pulp and small seeds have been found in the stomachs of a few dendrocolaptids, but it is unlikely that any woodcreeper consumes vegetable matter routinely. In a study of the stomach contents of five woodcreeper species from southern Mexico, Puebla-Olivares documented a suite of prey types for each. The Tawny-winged Woodcreeper took 26 types of prey, the Ivory-billed 20, the Olivaceous 18, and the Wedge-billed 12. The most important items in the diet of each species were spiders, beetles and wasps for the Tawny-winged Woodcreeper; spiders, caterpillars and various orthopterans for the Ruddy Woodcreeper; ants and beetles for the Wedge-billed Woodcreeper; beetles, spiders and ants for the Olivaceous Woodcreeper; and snails, beetles and orthopterans for the Ivory-billed Woodcreeper.

It is likely that all but the smallest woodcreepers take small vertebrates, in addition to arthropods. Small lizards, especially anoles (*Anolis*), constitute the most common vertebrate prey, especially for the ant-followers. In one study, vertebrates represented roughly 10% of the diet of the Plain-brown Woodcreeper. Skutch found that small lizards formed the bulk of items brought to nestling Tawny-winged Woodcreepers, although parents may preferentially feed young with such large prey. Some authors have speculated that lizards foraging at ant swarms are the most likely victims. Besides eating lizards, woodcreepers have been observed to take a variety of small frogs, salamanders, and even a few small snakes. Without question, the most unusual instance of a woodcreeper taking a vertebrate involved a Great Rufous Woodcreeper, observed as it pecked at and then ate a small bat.

Probably the biggest interspecific differences in dendrocolaptid diets are those between species that forage near the ground, over ant swarms, and species that pick or probe on trunks or other arboreal substrates. These differences are subtle, but, not surprisingly, ant-followers take a larger proportion of terres-

trial prey, such as grasshoppers and crickets, cockroaches, spiders and vertebrates, whereas arboreal woodcreepers consume proportionately more beetles, bugs and larvae. The White-chinned Woodcreeper is an opportunistic feeder, with the relative proportions of most prey taken approximating those of prey flushed by swarming ants, but it shows a strong predilection for grasshoppers and crickets, a weak liking for spiders, and a strong disdain for cockroaches. In the case of the Plain-brown Woodcreeper, however, deviation of the diet from samples of prey flushed by ants may reflect either a higher degree of selectivity or, more likely, a weaker dependence on ant swarms. Like the White-chinned Woodcreeper, the Plain-brown shows a preference for grasshoppers and crickets and a strong disdain for cockroaches, but, unlike that species, it takes many more beetles but many fewer spiders and ants than would be expected on the basis of samples of prey flushed by ants.

The diets of sympatric dendrocolaptids that feed by picking are extremely similar. The Buff-throated and Elegant Woodcreepers show an almost complete overlap in food preferences, despite their searching different substrates.

Chapman and Rosenberg concluded that the specialized foraging techniques used by woodcreepers do not result in specialized diets, at least not at the level of their study. A more detailed investigation, by Puebla-Olivares, revealed that dietary overlap was high but not complete, and that prey size may differ more than prey type. Taken together, studies by Puebla-Olivares and by Rocha and Peñaranda found that the diminutive Olivaceous and Wedge-billed Woodcreepers took primarily small prey, that the Long-tailed Woodcreeper fed on small and intermediate-sized items, and that the White-chinned, Tawny-winged, Ruddy, Ivory-billed and Buff-throated Woodcreepers captured prey of intermediate and large sizes. Pierpont, too, found variation in prey size across a suite of woodcreepers, with prey size positively correlated with body mass in sallying species, but only weakly so in woodcreepers that forage by picking.

**The Straight-billed Woodcreeper** is among the first birds to sing at dawn, and the last to sing at dusk. Whereas many woodcreepers seem to confine their vocal activity to these crepuscular moments, remaining virtually silent in daylight, this species also sings intermittently during the day. The frequency with which its voice is heard, particularly along Amazonian lakeshores and waterways, reveals its true abundance. It has been asserted that both sexes of woodcreepers sing, but it seems that in many species males alone give the true song; both sexes produce a variety of calls as a means of keeping in contact with their mates.

[*Xiphorhynchus picus picus*,  
Pantanal,  
Mato Grosso, Brazil.  
Photo: Haraldo Palo]

The song of the **Great Rufous Woodcreeper** is made up of a slightly descending series of two-parted "hic!-up" whistles, with a loud, ringing quality, and in this respect it is typical of the genus *Xiphocolaptes*. Because they tend to live in densely vegetated habitats, woodcreepers rely on voice as their primary means of communication. In common with most sub-oscines, most woodcreeper songs are not especially complex, but they are often loud and easily identifiable. Neither musical nor melodious, woodcreeper vocalizations tend to include sputtering or chipping trills, a series of whistles or double-whistles, explosive notes, whinnying sounds or prolonged rattles. In their various manifestations, they are among the most characteristic components of dawn and dusk choruses in Neotropical forests.

Calo]

Members of the genus *Lepidocolaptes*, such as the **Narrow-billed Woodcreeper**, forage using a classic woodcreeper technique, hitching. They climb trunks or large branches, often with a spiralling action, and while doing so they either glean prey from the bark's surface or probe with their slender bills into knotholes, vine tangles, moss clumps, or clusters of bromeliads and other epiphytes. Sometimes they use the bill to flake off or pry off bark in order to expose hidden prey. Woodcreepers usually forage singly, only infrequently or loosely accompanying their mates. Groups of woodcreepers consisting of more than a single pair are uncommon, and usually represent families, with one or both parents tending their dependent young.

### Breeding

Knowledge of the breeding biology of woodcreepers is limited. Much of what is known is derived from many years of observation by Skutch in Costa Rica, supplemented by studies by Oniki and Willis in South America. Two mating systems have been identified in the family. Most woodcreepers, especially the larger species, appear to be socially monogamous, with pair-bonds maintained throughout the year and both sexes taking part in all aspects of nesting and the rearing of young. By contrast, members of the genus *Dendrocincla*, and perhaps a few other woodcreepers, apparently do not form long-term bonds, instead being polygamous and, in the case of one species, possibly using leks.

In the cases of the Streak-headed and Spot-crowned Woodcreepers, the two species for which the data are most com-

plete, the mates share the tasks of nest-building, incubation, feeding of the nestlings, and care of the fledglings. It appears that these details apply also to other *Lepidocolaptes* species, as well as to members of the genera *Glyphorhynchus*, *Dendrocolaptes* and *Hylexetastes*. A Streak-headed Woodcreeper with abnormal plumage that nested on Skutch's ranch in Costa Rica allowed him to elucidate the relative effort expended by the male and the female. On the assumption that female woodcreepers incubate during the night, Skutch found that, in one season, the male spent much less time in incubating during the day than did its mate. In the following season, however, the sexes shared incubation duties more equally. Both parents brooded the newly hatched young, but the female not only brooded them for longer periods but also continued to brood them after the male ceased doing so. Provisioning rates were comparable for both parents. Although

Many woodcreepers join mixed-species flocks of birds that move through different forest strata in search of food. There are three main types of flock in tall forests: those of tanagers (Thraupidae) and other frugivores that travel through the canopy; those of *Hylophilus* greenlets and other canopy insectivores; and those of *Myrmotherula* antwrens, *Thamnomanes* antshrikes and other insectivores that travel through the lower and middle storeys. Most woodcreepers tend to accompany the third type, but a few species prefer the second; woodcreepers are rarely, if ever, found among flocks of frugivores. Even within broad categories of flocks, there are more specific preferences. At one site in Brazil, the **Planalto Woodcreeper** was found more frequently in understory flocks containing Cinereous Antshrikes (*Thamnomanes caesi*) than those without them. When not foraging with these flocks, it is often found with a different set of birds following army-ant swarms in the undergrowth, or it forages alone in the middle or upper storeys. At these times it seems to prefer trees with rough or mossy bark, rather than smooth or lichen-encrusted bark, and it occasionally peers into bromeliads.

[*Dendrocolaptes platyrostris platyrostris*, Río Pilcomayo National Park, Formosa, Argentina. Photo: José & Adriana Calo]

data for other dendrocolaptids are not so complete, several workers have noted that juveniles of a variety of woodcreeper species associate with both parents, and, in the case of the large species in the genera *Dendrocolaptes* and *Hylexetastes*, the young may remain with their parents for an extended period.

As mentioned in the preceding paragraphs, the breeding system of the genus *Dendrocincla* appears to differ from that of most of the Dendrocolaptidae. In the cases of the Plain-brown and the White-chinned Woodcreepers, the partners associate for only a brief period before one parent, presumably the female, takes on the duties of incubating the eggs and rearing the young. Willis noted that interactions begin aggressively, but the female soon accepts the male's advances. Some pair-members investigate possible nest-sites together, but the pair-bond seems to represent little more than this. Skutch's observations of another *Dendrocincla* species, the Tawny-winged Woodcreeper, confirm that one parent incubates and raises the young without assistance from its mate.

Although single-parent families are well known in the genus *Dendrocincla*, the reasons for the emancipation of males from the task of parental care remain unclear. Unlike most lekking species, the females of which feed their young with fruit or other abundant but often dispersed resources, woodcreepers focus instead on insects and small lizards, which are unlikely to be abundant in most circumstances. How females of species having the latter kind of diet succeed in provisioning the nestlings remains a puzzle. Willis speculated that the high degree of aggression displayed by these species, combined with dispersed but abundant food available at army-ant swarms, promotes this presumably polygamous system; even among those woodcreepers that forage primarily in association with ants, single-parent families are typical for some species but not for others. The Tyrannine Woodcreeper has taken this mating system a step further: during the breeding season, the males broadcast unusually loud songs from prominent ridgetops. Although unexpected for a plainly marked, insectivorous species, this behaviour recalls a mating system in which males gather on exploded, or dispersed, leks, a system that Willis and Oniki proposed as be-

ing the optimal one for a scarce species dependent on dispersed resources and occurring in a thickly vegetated environment. One can only speculate on the importance of phylogenetic inertia in forcing this species into a difficult situation, one in which the young are raised by a single parent in an environment less suited to this lifestyle than are the lowlands frequented by other *Dendrocincla* species.

The breeding cycle is complex. The members of Dendrocolaptidae, taken as a whole, breed in every month of the year, with year-round breeding likely to be the rule when considering the entire ranges of widespread species such as the Plain-brown, Wedge-billed and Olivaceous Woodcreepers. It is important, therefore, to examine patterns not only by species, but also by region. Woodcreepers in more northerly latitudes breed primarily during the boreal spring and summer, and those in southern latitudes during the austral spring and summer. Seasonality of breeding by populations living in equatorial regions is more difficult to assess, but it appears to be associated with seasonal rains. The majority of species breed either late in the dry season or early in the wet season, but some species in the Guianas and nearby regions breed during both the long and the short dry seasons. In addition, despite concordant seasonality of the rains in central and eastern Amazonian Brazil, the breeding seasons of woodcreepers may be, on average, somewhat earlier in the year in southern Amazonia than they are near Manaus. Indeed, Oniki and Willis found little seasonality of nesting in eastern Amazonia, near Belém.

Other aspects of breeding biology are remarkably constant throughout the family. All woodcreepers nest in cavities, in which they lay small clutches of white, unmarked eggs in a shallow cup, or on a bed of bark flakes or wood shavings. Woodcreepers place their nests in a variety of hollows. They are partial to natural cavities in rotting stumps or those created when branches break off trees, but various dendrocolaptids have nested in abandoned termite nests, between buttress roots, amid vine tangles, within hollow bamboo poles, and at the bases of palm fronds. There is no evidence that woodcreepers excavate their own cavities, even though some of them may enlarge the entrance to a pre-existing cavity. Several species use abandoned woodpecker holes, and

**The Northern Barred Woodcreeper** spends much of its time at army-ant swarms. Single birds, pairs, and occasionally small groups join swarms, where they are dominant over several other species of woodcreeper and antbird (*Thamnophilidae*). When not with ant swarms it is sometimes found in association with troops of monkeys, especially squirrel monkeys (*Saimiri*) and capuchins (*Cebus*). Mixed groups of these primates travel noisily through the subcanopy, generally causing havoc in search of fruit, small vertebrates and insects. Whenever living prey breaks from cover, or manages to escape, the accompanying woodcreepers are ready to pounce.

[*Dendrocolaptes sanctithomae sanctithomae*,  
Chan Chich, Belize.  
Photo: R. & N. Bowers/  
VIREO]

All woodcreepers are largely insectivorous, and the **Scimitar-billed Woodcreeper** is no exception. Its diet includes locusts, caterpillars and the larvae of beetles and ant-lions. It also consumes large quantities of non-insect prey, such as spiders, centipedes, millipedes and scorpions; it has even been recorded consuming vegetable matter on occasion. Unlike all other woodcreepers, it seems to take most food items from the ground, although it also forages in trees and cacti by probing into crevices and bromeliads.

[*Drymornis bridgesii*,  
Cayastá, Santa Fe,  
Argentina.  
Photo: Martín de la Peña]

the Scimitar-billed Woodcreeper has been recorded nesting in an abandoned nest of a Rufous Hornero (*Furnarius rufus*) and in a chimney. The Narrow-billed Woodcreeper, characteristic of open habitats, occasionally nests on bridge supports, cement columns, and a variety of other man-made structures.

Most woodcreeper nests have been found near the ground, a fact that may reflect a preference for low sites, or the availability of suitable cavities, or the ease for researchers of locating such sites. Of dendrocolaptid nests described in the literature, the majority have had entrances within 5 m of the ground, and few have been above 10 m. The entrances to some nests are only just above the ground, and, in a few instances, nest-cavities are subterranean.

The nest itself is either a shallow cup, lined sparsely with dark rootlets, dried leaves, stems or other plant fibres, or merely a bed of chips or flakes of wood or bark. Deep cavities may be filled with bark chips and wood flakes, upon which the nest is placed. The filling was nearly 50 cm deep in a cavity contested by both a pair of Streak-headed Woodcreepers and a female Tawny-winged Woodcreeper. The nest entrance is often a long, narrow slit, which can cause adults to contort the body when entering. Skutch documented that some nests have an entrance at the top, rather than at the side, so that the occupants are exposed to the elements. He speculated that roosting sites of this type indicate that protection from predators may be more important than protection from the elements, but Oniki found that flooding from heavy rains was a key cause of nestling mortality among Wedge-billed Woodcreepers near Belém.

As mentioned above, woodcreepers lay plain white eggs. Some authors have commented that the eggs can have a pinkish or greenish cast, but most have noted little more than a slight gloss. Looking at all members of the family, the eggs vary in shape and in size, the latter weakly correlated with body size. Clutches typically comprise two eggs, less frequently three. Three-egg clutches are regularly laid only by the Scimitar-billed Woodcreeper and members of the genus *Lepidocolaptes*, and a four-egg clutch may be unique to the Narrow-billed Woodcreeper. Clutches containing a single egg are occasionally laid by a variety of dendrocolaptids, but only some of the largest species, such as the Red-billed Woodcreeper, may routinely lay a single egg. There is no apparent correlation between clutch size and the system of parental care; because most woodcreepers lay either two or three eggs, however, such a correlation would be difficult to confirm, given the paucity of data. The Scimitar-billed Woodcreeper lays on consecutive days, but the Wedge-billed Woodcreeper lays on alternate days.

In most woodcreeper species, both sexes incubate the eggs. In the case of *Dendrocincla* species and possibly some members of other genera, however, only one parent, presumably the female, does so. Detailed observations by Skutch at a nest of Streak-headed Woodcreepers revealed that the eggs were tended for 60-66% of the observation period. In one season, Skutch observed 13 incubation sessions by the apparent female, these averaging 38 minutes, with a range of 7-72 minutes, but only three sessions by the male, which averaged 28 minutes and ranged from 15 to 42 minutes. In a

These photographs show **Narrow-billed Woodcreepers** with a variety of prey items including an adult lepidopteran, a centipede and the tail of a small lizard, the remainder of which presumably escaped! This same species has even been seen taking a small frog.

Judging from an examination of the stomach contents of specimens, most of its prey is 5-15 mm in length, and its diet comprises a variety of invertebrates not pictured here: ants, bees, various beetles, earwigs, bugs, cockroaches, caterpillars, flies, termites, and spiders. As befits the broad range of its taste, it is one of the most opportunistic woodcreepers, having adapted to a variety of man-modified environments. It is one of the few birds in its range that regularly forages on fence-posts and exotic Eucalyptus trees.

It has even been seen perching on a metal barrel catching flies, as well as sallying after moths and other insects attracted to streetlights well before dawn.

The **Lineated Woodcreeper** is one of very few dendrocolaptids adapted to life in the canopy of rainforest, where it spends most of its time following flocks consisting largely of greenlets (*Vireonidae*), tanagers (*Thraupidae*) and tyrant-flycatchers (*Tyrannidae*). It forages less on trunks than most woodcreepers, and more on large branches, often hitching along the underside of these when they are angled or horizontal. It is never seen in the understorey, although it sometimes descends to the middle storey in the absence of competitors of the genus *Xiphorhynchus*, which normally dominate access to resources.

[*Lepidocolaptes albolineatus fuscicapillus*, Tambopata-Candamo Reserved Zone, Peru. Photo: Tui de Roy]

subsequent season, the female of this same pair completed eleven sessions, with a mean duration of 27 minutes and a range of 5-57 minutes; the male's eight sessions lasted for 16 minutes on average, with extremes of 6 and 37 minutes. The nest was left untended 14 times in the first season, for periods of 2-41 minutes, with a mean of 21 minutes, and 17 times during the second, when periods of absence were similar, at 4-41 minutes, with an average of 17 minutes. The behaviour of a pair of Spot-crowned Woodcreepers was similar, although these birds tended the nest for 82% of the observation period, with the incubating bird more often waiting for its mate to arrive before it departed from the nest.

Incubation patterns shown by the Tawny-winged Woodcreeper are different. Skutch reported that the lone parent, presumably the female, spent longer periods incubating, but also longer periods away from the nest. During one morning of observation, the sitting bird remained on the eggs for three periods of 47-87 minutes' duration, these separated by recesses of 26 and 39 minutes. In all, the incubating bird tended the eggs for just over 60% of the time, a figure comparable to the total time that both members of the Streak-headed Woodcreeper pair spent on their eggs.

In woodcreepers incubating adults often return to the nest with a small piece of wood or bark. In fact, this behaviour was used by Skutch to determine the time of hatching, because the pieces of nest material were replaced by food items as soon as the young hatched and needed to be fed. The continued addition of inedible items to the nest throughout the incubation period is most interesting, but its function remains unknown.

The incubation and nestling periods of woodcreepers are poorly known, but those species in which the pair-members cooperate in these duties have shorter periods than do those in which only one parent cares for the young. From the limited information available, the relatively large Scimitar-billed Woodcreeper has the shortest incubation period, lasting 14 days, but its nestling period is of an average duration of 21 days. The shortest nestling period in the family is that of the tiny Wedge-billed Woodcreeper, the young of which leave the nest after 17 days. *Xiphorhynchus* and *Lepidocolaptes* species of comparable size have incubation and nestling periods of comparable length. For example, the Elegant Woodcreeper incubates for at least 16 days and tends its chicks for 18-19 days, whereas the Cocoa Woodcreeper tends its nestlings for 20 days, during which a sin-

gle parent may raise the young alone; in *Lepidocolaptes*, the Streak-headed Woodcreeper incubates for 15 days and tends its nestlings for 18-19 days, the respective periods for the closely related Spot-crowned Woodcreeper being 17 days and 19 days. Species in the genus *Dendrocincla* require longer, probably because the single parent has less time to devote to incubation and to the feeding of its brood. For example, the Tawny-winged Woodcreeper incubates the eggs for 20 or 21 days and tends nest-

The **Lesser Woodcreeper**, seen here in possession of a large beetle larva, rarely forages on branches. It spends most of its time on trunks, climbing these from the understorey to medium levels, often ascending only a short distance before moving on to the next tree. For this reason, it is generally encountered less than 5 m up, and usually within 15 m of the ground. Despite an apparent preference for using larger than average trees, most of its actual foraging time is spent on sections of trunks that are relatively slim.

[*Xiphorhynchus fuscus atlanticus*, Alagoas, Brazil. Photo: Anita Studer]

The **Great Rufous Woodcreeper** frequents the same Chaco woodlands as the Scimitar-billed Woodcreeper (*Drymornis bridgesii*). Likewise, it forages terrestrially, although not as often, nor with the same dexterity: *Xiphocolaptes* hops clumsily whereas *Drymornis* runs with ease. Despite this handicap, the Great Rufous Woodcreeper descends regularly to rummage through leaf litter or dig in soft earth, especially in open habitats. At such times, it somewhat resembles a flicker (*Colaptes*). Its diet consists mainly of arthropods, but also includes vegetable matter, snails and fairly large frogs, much of which it probably finds while foraging on the ground. It has even been reported attacking a 40-cm long snake and eating a bat.

A few woodcreepers in the genera *Hylexetastes*, *Dendrocolaptes* and *Dendrocincla* are regular followers of ant swarms. The **Plain-brown Woodcreeper** is one such species, regularly joining the mixed groups of thamnophilid antbirds that accompany swarms. As with antbirds, it is not the ants that the woodcreepers are after, but the invertebrates that the ants flush from shelter. The foraging technique of these woodcreepers at swarms is different from their usual style: they climb less and spend more time waiting for prey to move. From their perches on slender stems (often covered in ants, as here), they swoop on any insect that breaks cover.

[*Dendrocincla fuliginosa* ridgwayi, Soberania National Park, Panama. Photos: Marie Read]

lings for 24 days, and the Plain-brown Woodcreeper tends its nestlings for 23-25 days.

Nestling woodcreepers are fed with a variety of prey, usually one item at a time, and in most cases by both parents. In species of *Dendrocincla* and possibly other genera, however, only one parent feeds the chicks. There is a tendency for the adults to deliver small prey to younger nestlings, but larger prey to older young. Some authors have further suggested that the parents provision young with relatively large items, perhaps compensating for their intermittent visits to the nest. The large size of some prey sometimes makes identification possible. Skutch noted that a Tawny-winged Woodcreeper provided its young with insects when they were small, but mostly with small lizards, and a few spiders, after the chicks were a week old. The Northern Barred and Cocoa Woodcreepers also bring small lizards to the nest, but the Streak-headed and Spot-crowned Woodcreepers deliver chiefly brown insects, and the Wedge-billed Woodcreeper delivers tiny items that are almost impossible to identify in the field. The stomach contents of two nestling Lesser Woodcreepers comprised spiders, orthopterans and a beetle larva.

Provisioning rates vary, depending in part on the number of parents involved. Skutch found that, during a five-hour period, a female Streak-headed Woodcreeper brooded its two-day-old chicks for 131 minutes, and the male brooded them for 43 minutes, the parents bringing food to the nest 16 times in total. During a subsequent four-hour period, the female alone brooded the eight-day-old young only briefly, and the parents visited the nest 21 times. Finally, when the young were 15 days of age, they were not brooded at all, even during the night, and the parents delivered food to the nest 32 times during a three-hour period. Provisioning rates and prey types were similar for the Spot-crowned Woodcreeper. By comparison, a female Tawny-winged Woodcreeper likewise brooded her young frequently when they were newly hatched, but her provisioning rates were substantially lower than were those of the two *Lepidocolaptes* species. During multiple six-hour periods, the female visited the nest six times when it contained a single day-old nestling, nine times when there were two nestlings aged 3 days, twelve times when the young

were aged 9 days, and 16 times when they were 17 days old. Thus, provisioning rates by a lone parent were less than half those at *Lepidocolaptes* nests attended by two parents. The Tawny-winged Woodcreeper may, however, compensate by bringing larger prey to the nest. Skutch also reported that nestlings of species with biparental care are much more vocal than are those tended by a single parent. Perhaps young with single parents are quieter because of the increased risk of predation.

Fledgling woodcreepers remain with their parents for an extended period, with those of large species apparently being dependent on their parents for longer than are fledglings of small

This race of the **White-chinned Woodcreeper** is best identified, not by its chin, but by its pale blue eyes. It is an obligate ant-follower, sometimes gathering in small groups at large swarms. When not at swarms, individuals sometimes forage in association with herds of white-lipped peccaries (*Tayassu pecari*). These malodorous pigs flush prey much like swarming ants. One White-chinned Woodcreeper was even seen perched on a peccary, which may explain the peccary-like aroma of many mist-netted individuals.

[*Dendrocincla merula bartletti*, Cocha Cashu, Manu National Park, Peru. Photo: Gustavo Londoño]

Most ant-following birds rarely eat army ants; if and when they do so, it is by accident. It is the arthropod disturbed by the ants that provides the meal, as it hops, scuttles or flutters from its hiding place, desperately seeking new shelter. Fleeing insects will often have ants attached to them, and it is generally at these times that the ants themselves are inadvertently eaten.

This **Planalto Woodcreeper** is holding prey that was caught at the periphery of an ant swarm, in the mountains of south-east Brazil. This species is frequently found with ant swarms, often alone, but sometimes in pairs. At these times females are dominant over males. Both sexes are dominant over smaller antbirds, tanagers, and Dendrocincla woodcreepers, but they are usually subordinate to the Buff-throated Woodcreeper (*Xiphorhynchus guttatus*).

Pecking orders at ant swarms are usually well defined.

[*Dendrocolaptes platyrostris platyrostris*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

Members of the genus *Dendrocincla*, and perhaps a few other woodcreepers, are polygamous. As for the remainder of the family, the **Narrow-billed Woodcreeper** is typical in that it appears to be socially monogamous. Pairs remain in association throughout the year, sharing the defence of large, multi-purpose territories, in which they forage and breed. All woodcreepers nest in cavities, usually in trees. The nest-site might be a natural hole, as here, or an old woodpecker (*Picidae*) excavation. In this species, nest entrances are generally fairly low, from just above ground level to 4 m up. The cavities range from 20-160 cm in depth, and often have a surprisingly narrow entrance, which may be slightly enlarged and rounded by the birds. When nest entrances are long, narrow slits, adults may be forced to contort the body when entering.

[*Lepidocolaptes angustirostris angustirostris*, Rio Pilcomayo National Park, Formosa, Argentina. Photo: José & Adriana Calo]

Although most species of woodcreeper are only known to nest in trees, the **Narrow-billed Woodcreeper** has been reported nesting in various situations. Recorded nest-sites have included holes in cement columns, bridge supports, and other man-made structures. In some regions, including the Pantanal, they regularly use holes in termite nests. Such holes have usually been excavated by another species of bird, in this case probably a **Campo Flicker** (*Colaptes campestris*).

[*Lepidocolaptes angustirostris bivittatus*, Pantanal, Mato Grosso, Brazil. Photo: Michel Günther/Bios]

species. At the extreme, young Red-billed Woodcreepers may remain with their parents until early in the year after fledging, but for most species the period of dependence probably lasts for no more than a few months. There is no evidence that fledglings return to their natal cavities to roost; instead, they either locate or are shown alternative roosting sites.

When dual parental care is the case, the parents either will travel together with their offspring, as a group, or will split up, with each parent then accompanying a single fledgling. For those

species in which the young are raised by a single parent, groups of three birds probably represent mothers with their offspring. Willis noted that family groups of ant-followers forage away from ants when the young are only recently fledged, but attend swarms together when fledglings are older. He also noted a moderate degree of aggression between parents and young, manifest in some species as the young being dominant over one parent, presumably their father, but subordinate to the other, presumably their mother. Over time, aggression by parents probably increases until, finally, the young leave the natal territory.

## Movements

In common with most birds frequenting the interior of Neotropical forests, dendrocolaptids are largely or exclusively sedentary. There is no evidence to suggest that any woodcreeper species is truly migratory, although limited, anecdotal evidence indicates that some do wander short distances. A small degree of altitudinal movement probably takes place near mountains in Central America, especially in Mexico, near the northern limit of the family's distribution. The White-striped Woodcreeper, for example, has occurred at unusually low elevations in southern Sonora and, similarly, the Spot-crowned Woodcreeper has wandered to the Caribbean lowlands from Mexico south to Costa Rica. Records of the Ruddy and Long-tailed Woodcreepers from La Selva Biological Reserve, in Costa Rica, suggest some downslope movement, because these species normally frequent higher elevations in nearby foothills. The Black-banded and Strong-billed Woodcreepers have shown similar downslope movement in Honduras. Conversely, records from Monteverde Forest Reserve, also in Costa Rica, imply that some lowland species, such as the Wedge-billed Woodcreeper, move upslope after breeding. Nonetheless, long-term studies at various sites have documented the year-round presence of most species at most sites, demonstrating that movement, when it does occur, probably represents wandering by a few individuals, rather than migration by the population as a whole.

Few woodcreepers occur on islands, even continental ones only a few kilometres offshore, further attesting to their sedentary nature. Only Trinidad harbours more than two dendrocolaptids, and even there the complement of five woodcreeper

As in most widespread species of woodcreeper, the **Red-billed Scythebill** does not have a clearly defined breeding season throughout its range.

Although it may nest seasonally at particular sites, its overall range is so broad, and climatic patterns within this range so varied, that breeding probably takes place all year round. Only a few nests have been reported, however, these being sited in tree cavities or hollows formed inside broken stumps; in this case, it is a palm stump from which the centre has rotted out. In some cases, the nests of woodcreepers are located very close to the ground, or in cavities so deep that they are actually subterranean.

[*Campylorhamphus trochilirostris lafresnayanus*,

Kaa-Iya del Gran Chaco National Park, Bolivia. Photo: Luiz Claudio Marigo]

In most woodcreepers, especially the larger species, both sexes take part in all aspects of nesting and the rearing of young. One of the first parental duties during the breeding season is nest preparation. This is achieved by dropping bark flakes or wood shavings into a suitable cavity to form a soft bed. Once a shallow cup has been formed, a small clutch (usually two) of unmarked white eggs is laid. During incubation, many woodcreepers repeatedly return to the nest with small pieces of wood or bark. The function of this interesting behaviour is unknown, although it must have the effect of augmenting the bed of soft material. When the eggs hatch, the adults tend to carry in no more nest material, instead bringing items of food for their hungry chicks. So distinct is this switch in adult behaviour that it can be used to estimate the timing of hatching. The bill of this **Cocoa Woodcreeper** is crammed with wood-chips, and for this reason we can be fairly sure that its eggs have not yet hatched.

[*Xiphorhynchus susurrans*  
nanus,  
Gamboa, Panama.  
Photo: Marie Read]

As woodcreeper chicks usually lurk at the bases of dark cavities, very little is known about them. This **Elegant Woodcreeper** is just a few days old, still blind, and still bearing the fluffy down which was present shortly after hatching. The incubation period in this species is estimated at 16 days, and the nestling period at 18-19 days. This latter phase is more protracted in those woodcreeper species in which males do not contribute to parental care.

[*Xiphorhynchus elegans insignis*,  
Cocha Cashu,  
Manu National Park, Peru.  
Photo: Gustavo Londoño]

species is greatly reduced in relation to that found in the forests of coastal Venezuela, within sight of the island. Apart from Trinidad, the only islands supporting woodcreepers are Tobago, which has one species, and Isla Margarita, off northern Venezuela, where two species are found. The loss of at least one, and possibly two, species from Barro Colorado Island since its isolation from the Panamanian mainland testifies to the inability of woodcreepers to colonize suitable habitat across even a narrow water barrier.

A further demonstration of the sedentary nature of woodcreepers is provided by ringing studies. Ringing returns from a variety of sites have involved individuals recaptured on the same territories several years after they were initially ringed. Moreover, all five Tawny-winged Woodcreepers and three of four Olivaceous Woodcreepers captured at a site in Mexico returned to their territories shortly after having been being deliberately displaced.

## Relationship with Man

Considering their inconspicuous songs, drab plumage, small size, retiring habits, and the forested habitats they frequent, the relationship of woodcreepers with humans is predictably limited. Only the most astute human denizens of tropical forests distinguish between woodcreepers and woodpeckers. For example, Amazonian *campesinos* and *caboclos* often refer to woodcreepers as *carpinteros* or *pica-paus*, the same terms as those that they use for woodpeckers. Some observers are aware of the generally reddish coloration of woodcreepers, and the better woodsmen, or *mateiros*, notice that these birds rarely peck at wood in the manner of woodpeckers, but, in general, dendrocolaptids evade detection.

Woodcreepers are not hunted in any numbers, probably because even the largest species are not worth the effort. Even the moderately large Moustached Woodcreeper, the only dendrocolaptid considered to be globally threatened (see Status and Conservation), is believed to be adversely affected by habitat loss, but not by hunting. The dull plumage patterns and unremarkable songs of woodcreepers afford them little popularity among aviculturalists; likewise, their earth-toned feathers are unlikely to be prized by indigenous peoples. Thus, the only interaction between man and woodcreepers is an indirect one: the adverse impact of man that results from the loss and fragmentation of the mature forests that most dendrocolaptids need for their survival (see Status and Conservation).

## Status and Conservation

As woodcreepers are mostly inconspicuous birds of the forest interior, direct human exploitation does not constitute a threat to them. Among their natural enemies, snakes seem to be regular predators at woodcreeper nests, feeding on both eggs and nestlings, and forest raptors probably take a few juveniles and adults. Without doubt, the major threat to the long-term survival of the members of this and many other avian families is loss and fragmentation of the forests in which they live. Forest clearance and fragmentation, primarily through logging and for agriculture, have increased tremendously in the last 50 years

Two adult **Narrow-billed Woodcreepers** perch momentarily at the entrance to their nest, one carrying a beetle for its brood. In this species, as with most woodcreepers, both adults share the duty of feeding the nestlings. The items that they deliver are not regurgitated, but are carried to the nest in the bill tip, one at a time. The size of items delivered increases as the nestlings age. For this reason, woodcreeper chicks might receive small insects in the first week after hatching, and lizards during the last week before fledging. By delivering the largest consumable prey items at any given time, parents minimize the frequency of their visits.

[*Lepidocolaptes angustirostris bivittatus*,  
Minas Gerais, Brazil.  
Photo: Anita Studer]

throughout the Neotropics, and many projections indicate a continuing escalation in habitat destruction for several decades to come.

The Moustached Woodcreeper is the only dendrocolaptid currently listed as globally threatened, being designated as Vulnerable. Not only is this species uncommon and local throughout its range, but it requires intact or, at most, only slightly disturbed tracts of semi-deciduous or dry forest that grows on the richest soils in the interior of north-eastern Brazil. Sadly, forests in this region are being converted at an alarming rate to charcoal, used to fuel the steel and pig-iron industries. In addition, large-scale irrigation projects promote clearance of dry forest for agriculture. As a consequence, it is estimated that less than 5% of the area originally covered by tropical dry forest in north-eastern Brazil will remain intact in the near future. Illustrating the rapidity of the destruction of dry forest, and the concomitant threat to the Moustached Woodcreeper, a large tract of undisturbed forest near Coribe, in the state of Bahia, harboured a substantial population of these birds in 1988, but had been completely cleared by 1993. Under such pressures, local populations of the Moustached Woodcreeper disappear or, at best, are reduced and fragmented, a situation that seriously threatens the species' long-term survival. Although the Moustached Woodcreeper is protected under Brazilian law, the most important step towards its preservation will be the establishment of a network of conservation areas across the interior of north-eastern Brazil aimed at protecting undisturbed tracts of dry forest. Despite the recent creation of several reserves in the region, most notably Serra do Baturité State Environmental Protection Area, in Ceará, and Cavernas do Peruaçu National Park, in Minas Gerais, a network of reserves still did not exist in 2001.

The only woodcreeper currently regarded as Near-threatened is the Greater Scythebill. This poorly known species is uncommon to rare and locally distributed along a narrow and discontinuous belt of montane forest in the middle and upper elevations of the central and northern Andes. It is likely that

some of its populations were extirpated as a result of recent clearance of large tracts of montane forest along river valleys in northern Peru, Ecuador and Colombia. Additional data are sorely needed to enable an accurate assessment of this species' conservation status.

The Tyrannine Woodcreeper is another uncommon and local species restricted to montane forest in the Andes. It was included in a preliminary "blue list" for Colombia, and probably merits consideration as being globally threatened. The Tyrannine Woodcreeper is somewhat better known than the Greater Scythebill, unlike which it has been reported, if only rarely, in older second growth, at forest edges and even in clearings, perhaps indicating some degree of tolerance of habitat disturbance. Regardless of that possibility, any species that occupies a narrow elevational belt of montane forest in the Andes is at moderate risk, not only from habitat loss, but also from episodic natural catastrophes such as earthquakes and volcanic eruptions.

As 0woodcreepers are sedentary and, in most cases, favour the forest interior, even locally abundant species are vulnerable to forest destruction and fragmentation. For example, a protected forest fragment in south-eastern Brazil was inhabited by the Plain-winged, Olivaceous, Planalto and Lesser Woodcreepers and the Black-billed Scythebill (*Campylorhamphus falcularius*), but all five species disappeared from the site between 1975 and 1992. Possible explanations were the loss and degradation of most of the undisturbed forest at the site, combined with the fragment's extreme isolation, which prevented recruitment and establishment of immigrants from neighbouring source areas. Only those species capable of crossing large unforested gaps, a category which excludes these woodcreepers, were able to recolonize the remaining 250-ha fragment. Local extinction of the Northern Barred Woodcreeper on Barro Colorado Island, following its isolation when Gatún Lake was created during the construction of the Panama Canal, further illustrates the inability of woodcreepers to disperse across a water barrier. These

This **Spot-crowned Woodcreeper** is about to deliver food to its nestlings in a mossy cloudforest tree. Begging chicks are unusually noisy in this genus, and as such their calls are easily audible from outside the nest. After roughly 19 days, during which time they are provisioned with insect larvae, spiders, cockroaches, and other items, they will fledge. As with most woodcreepers, the young do not return to the nest after once leaving it, but continue to be fed by both parents. In most cases on record, there appears to be no division of the brood: juvenile woodcreepers typically associate with both parents, often for at least a month, and in some cases considerably longer.

[*Lepidocolaptes affinis neglectus*,  
Rancho Redondo,  
San José, Costa Rica.  
Photo: Manuel Marín]

The only dendrocolaptid currently considered threatened with extinction is the **Moustached Woodcreeper**, a species that only occurs in undisturbed dry or semi-deciduous forest on rich soils in the interior of north-eastern Brazil, a habitat that is itself very local and uncommon. The patches that remain are disappearing rapidly as trees are cleared to produce charcoal and to make way for the expansion of irrigated agriculture. To halt the decline in this species an effective system of protected areas is required, alongside the promotion of sustainable forest use at all unprotected sites.

[*Xiphocolaptes falcirostris franciscanus*, north of Itacarambi, Januária, Minas Gerais, Brazil. Photo: Juan Mazar Barnett]

and other studies illustrate that the detrimental effects of habitat fragmentation can result in the complete disappearance of woodcreepers even from protected sites.

Habitat fragmentation is a serious threat to woodcreepers even in vast areas of undisturbed forest in the Amazon Basin. In central Amazonia, small fragments of forest may not contain enough active army-ant colonies to support birds that rely on them. Hence, species such as the White-chinned, Red-billed and Black-banded Woodcreepers disappear rapidly from fragments smaller than 100 ha, and their numbers are much reduced even in larger fragments. Those that forage mostly with mixed-species flocks, such as the Spot-throated Woodcreeper, are also adversely affected by forest fragmentation, largely because most flocks wander over an area of at least 10 ha. Mixed-species flocks often disband following fragmentation, with the result that species that are obliged to forage with flocks disappear quickly, leaving only those that are efficient solitary foragers. Only species possessing sufficient flexibility in their diet and foraging behaviour, such as the Plain-brown, Wedge-billed and Chestnut-rumped Woodcreepers, persist in small fragments in similar or slightly increased numbers.

Moreover, fragments are not nearly so isolated from continuous forest at Amazonian sites as they are in the Atlantic Forest of south-eastern Brazil, where rapid and extensive development around some of the largest cities in the world, most notably São Paulo and Rio de Janeiro, has reduced once continuous forest to small, isolated patches. The loss and fragmentation of forest is even more evident farther north, in coastal eastern and north-eastern Brazil, where little intact forest remains and many woodcreeper populations are threatened. Most at risk in the coastal lowlands of eastern Brazil are several endemic subspecies: race *taumayi* of the Plain-brown Woodcreeper, *cuneatus* of the Wedge-billed Woodcreeper, and the nominate races of both the Buff-throated Woodcreeper and the Red-billed Scythebill. Farther inland, the northernmost population of the Scaled Woodcreeper, the subspecies *wagleri*, occurs together with the Moustached Woodcreeper in woodland that is severely threatened, although *wagleri* appears to be less sensitive to the degradation and fragmentation of woodland than is the larger species.

Less invasive methods of forest exploitation, such as selective logging, can also have an adverse effect on woodcreepers. The direct removal of trees, and incidental loss occurring when roads are built for transporting timber out of logging concessions, combine to simplify the forest's structure, principally through drastic changes in understorey and mid-storey vegetation. Even when not removed completely, the understorey and mid-storey of selectively logged forest receive an increased amount of solar radiation, leading to micro-climatic changes that disrupt the life-cycle of the arthropods upon which understorey woodcreepers rely. Because the forest canopy is in effect an edge environment, such species as the Lineated Woodcreeper, which forage primarily in the canopy, may be better able to tolerate the degradation and fragmentation that result from selective logging. Besides food scarcity, a loss of suitable nesting sites may explain why fewer species of woodcreeper inhabit second growth and selectively logged forest when compared with primary forest. The preferred nesting sites of woodcreepers, both natural cavities and holes excavated by woodpeckers, are scarcer in the absence of large trees and decaying stumps. Some researchers have suggested that nestboxes will help to maintain woodcreepers in degraded habitats, although this idea has not been tested. It is probably no coincidence that those few dendrocolaptid species that frequent disturbed habitats have been found nesting in a variety of atypical sites, including man-made structures (see Breeding).

Although loss and fragmentation of forest threaten most woodcreepers, a few species are adapted to more open situations. Most notably, the Narrow-billed Woodcreeper, a typical inhabitant of *cerrado*, is gradually extending its range in south-eastern Brazil to occupy sites that were, until recently, blanketed by dense Atlantic Forest. This species quickly exploits resources not available naturally in the wild. It is also one of few woodcreepers that regularly nest in man-made structures, such as bridge supports and cement columns (see Breeding), and it has been observed while foraging on insects attracted to streetlights and refuse barrels. The Streak-headed and Straight-billed Woodcreepers also frequent open habitats, and both seem to have little difficulty in co-existing with humans. One author speculated that the Tawny-winged Woodcreeper was likely to expand its range southwards, because it is less sensitive to habitat disturbance than are the aggressive antbirds that now exclude it at some sites.

Numerous studies have shown that species diversity, not only of woodcreepers but also of most other groups, is maximized when there is a diverse array of continuous and undisturbed habitats in close proximity. Protection of large tracts of undisturbed forest is, therefore, the best way in which to ensure the long-term survival of these birds. Given the inability of most woodcreepers to cross even the narrowest of gaps in forest, a connectivity of forest fragments is also important. Recent work has shown, for example, that narrow forest roads represent enough of a gap to delimit the territories of understorey flocks that some woodcreepers join. As many woodcreepers are sensitive to even minimal changes in habitat quality, their persistence is a natural indicator that can be useful for monitoring ecosystem health throughout Neotropical forests and woodlands.

Olivaceous Woodcreeper (*Sittasomus griseicapillus*); 10. Wedge-billed Woodcreeper (*Glyphorhynchus spirurus*).

**Habitat.** Humid forest in lowlands and foothills. Primarily evergreen forest, less frequently gallery, deciduous and lower montane forests, forest on sandy soils, and cloudforest; occasionally mangroves. Amazonian populations occur principally in *terra firme*, floodplain and river-edge forest, less frequently in flooded habitats or swamp-forest. Generally in interior of mature forest, but regularly frequents edge and older second growth; sometimes enters younger second growth, bamboo thickets, and plantations. At one site captured slightly more frequently within unbroken forest than at treefall gaps. Largely a species of understorey and mid-levels, less often subcanopy, but rarely higher; sings from relatively low perches. Mainly below 1300 m in tropical lowlands, but to nearly 2000 m in lower subtropical zone, apparently reaching highest elevations in coastal N Venezuela and N Colombia; few remaining populations seem to occur above 1400 m.

**Food and Feeding.** Diet largely arthropods and other invertebrates, but small vertebrates also regularly taken. Stomach contents from various South American sites primarily beetles and orthopterans, followed by spiders and small vertebrates (especially small lizards) and, in smaller quantities, various Hymenoptera, bugs (Hemiptera) including cicadas (Cicadidae), cockroaches (Blattodea), insect larvae, moths, damselfly (Zygoptera) imagoes, and unidentified neuropterans. Of four dendrocolaptids examined in one study, present species took largest percentage of vertebrates. Comparison of stomach contents with prey flushed by army ants revealed that beetles and orthopterans are taken preferentially, but cockroaches, spiders and ants avoided; prey observed being taken over swarming ants primarily orthopterans, cockroaches and spiders, with lesser numbers of beetles, moths, centipedes (Chilopoda), scorpions, large ants, cicadas, lizards (mostly *Anolis limifrons* at one site), and other items, but data biased by ease of observation. Also seen at dawn to take variety of moths attracted to lights during previous night (but seems to avoid some Geometridae). Prey often quite large for size of bird, regularly 30–40 mm, and sometimes exceeding 100 mm in length; larger items often beaten against trunk, but never held in feet. Although high dietary overlap with other woodcreepers studied (especially *Xiphorhynchus*), behavioural overlap was relatively low. One author suggested that 60–90% of food was taken over ants by members of “*meruloides* group” (with foraging almost exclusively over ants in Trinidad), but members of “*fuliginosa* group” may forage at higher levels and thus less dependent on ants. Despite extensive use of swarms of army ants (largely *Eciton burchelli*, also *Labidus praedator*), often considered a facultative rather than an obligate ant-follower because it regularly forages alone, sometimes with mixed-species flocks, and occasionally in association with monkey troops; unlike most “professional” ant-followers, exploits ants only when they pass through its territory. Use of ant swarms at one site was highest during dry season, lowest during wet season. Usually 1–3 birds encountered at ant swarms, but 4–5 not uncommon, and up to 12 recorded; larger numbers generally found in absence of interspecific competitors (especially in Trinidad). Forages actively over swarms for much of day. Most attacks involve sallies (over 90% in one study), usually to trunks, stems or vines (30–60% in all), less frequently to foliage (c. 25%), the ground (20%) or epiphytes (8%), or aerial pursuits (10–30%); also regularly pecks or gleans prey from surface of trunks (over 20% in another study), less frequently vines or stems, and rarely other substrates; rarely, tosses leaves, hammers on wood, pries off bark, or probes epiphytes or other substrates. Over ants, perches most often on relatively slim (5–15 cm), nearly vertical trunks at periphery of swarm, mostly within 4 m of ground but regularly to 10 m or more. Foraging heights vary depending on presence of competing antbirds, e.g. Ocellated Antbird (*Phaenostictus mcleannani*); in their absence, usually uses perches within 3 m of ground, taking most prey in sallies to ground but when antbirds present, often excluded from perches below 2 m, and relegated to foraging at higher levels. Sallies directed both above and below perch, mostly to targets within 3 m of perch, and almost always within 6 m. Most observations away from ants involve solitary birds, less frequently two, rarely three together (many such groups probably female with young); away from ants, forages higher up (mostly 3–15 m) in mid-levels of forest, usually by sallies to distant foliage or trunks, less often by pecking. Perches crosswise on horizontal branches only occasionally, but still more frequently than do other woodcreepers. Apparently less aggressive than many ant-followers, perhaps reflecting its generally subordinate status; intraspecific aggression common but undistinguished, usually involving supplanting, chases, and occasionally pecking or fighting. Regularly supplants only a few smaller species; conversely, is often supplanted or displaced by *Phaenostictus mcleannani* and by most larger woodcreepers, especially *D. merula* and three *Dendrocolaptes* species (*D. certhia*, *D. sanctithomae*, *D. picumnus*), and, less frequently, by various other species. Often excluded from foraging low over ants, and sometimes forced to forage away from them altogether. Despite regularity of foraging away from army ants, behaviour is typical of “professional” ant-follower: follows same ant colony for extended period of time, but shifts readily from swarm to swarm; monitors inactive colonies, and may return to same one following period of inactivity; homes in on vocalizations of other ant-followers, apparently to locate swarming ants; tracks lines of ants back to swarm. Attends mixed-species flocks in forest understorey only on occasion (6% of the time during radio-tracking work at one site); seems to prefer flocks led by *Thamnomanes* antshrikes. Frequently flashes wings to flush prey, and regularly seen “anting” with small items, most of which are later consumed.

**Breeding.** Nesting season May to early Oct in Costa Rica, Panama and Trinidad, apparently a little earlier in Guyana and somewhat later in N & C Amazonia; in Brazil, nest-building late Aug to early Sept and nest with eggs in early Jan in Belém, nestlings being fed in late Feb in Pará, and fledglings fed in early Aug to mid-Jan and late Mar to late May at various sites in Amazonia; nestlings in late Apr in Colombia, early Jun in Panama and early Sept in French Guiana; dependent young in Jun–Oct in Panama, late Oct in French Guiana and Nov–Dec in Trinidad. Pair-bond brief and rudimentary, with high degree of aggression between mates. Minimal courtship; mates sometimes inspect cavities together or closely chase each other through forest. Nest usually 1–10 m up in cavity of hollow stump, palm branch or bamboo pole, often within forest but sometimes in adjacent clearing, a well-lined cup comprising dead leaves and petioles, fibres, rootlets, plant and seed down, and sometimes feathers, often placed on bed of mosses and often built well below cavity entrance. Clutch 1–3 white eggs, usually 2, average 25.5 × 19.5 mm; parental care exclusively by female, which alone has brood patch, and which appears to be dominant over male; nestlings fed only infrequently, average of 46 minutes (maximum nearly 3 hours) between visits at one nest; most items brought to nest (cicadas, lizards, cockroaches, orthopterans) were quite large, often exceeding bill length of female; nestling period 23–25 days; young usually well grown before brought to ant swarms by female. Estimated mean annual survival nearly 70% in Panama and nearly 80% in Trinidad; three females ringed on Barro Colorado I (Panama) lived at least 8 years, with one recaptured after nearly 11.5 years, and three individuals in Trinidad recaptured 8–10.5 years after ringing.

**Movements.** Apparently resident in most of range; unusual fluctuations in abundance at sites in Costa Rica reported as possibly reflecting local migration, but this not supported by recent observations. Females have virtually exclusive territories that overlap completely with those of males; males may wander away more from their territories, which may overlap. “Unsettled” birds wander extensively but, once settled on a territory, often remain there for many years.

**Status and Conservation.** Not globally threatened. Most common and widespread member of genus; uncommon to fairly common or locally common over most of its range, from Costa Rica to S Venezuela, Ecuador and most of Amazonia; apparently more common in Trinidad than elsewhere. Geographically isolated race *taunayi* fairly common in what little forest remains within its limited range in

NE Brazil. Much less common at upper elevations (rare above 1400 m), and scarce at N edge of range and in marginal habitats of dry lowlands of NW Costa Rica. Has seemingly disappeared from former range in Cauca Valley (Colombia). Population on Barro Colorado I (Panama) estimated in one study at 100 individuals, with the species believed to occupy 95% of island’s area. Densities on Barro Colorado I were 6–7 birds/100 ha (2–8 “settled” females, 1–8 “settled” males, and additional floaters), with females having home ranges of c. 36 ha; estimated densities in floodplain-forest in SE Peru a little higher, at 8 birds/100 ha (with territories estimated at 13–16 ha), and those in nearby late-successional growth higher still, at 10–12 birds/100 ha; densities in *terra firme* forest in both SE Peru and French Guiana much lower, only 1–2–6 birds/100 ha. Considered highly sensitive to forest fragmentation and other forms of human disturbance; appears, however, to be less sensitive than are “professional” ant-followers in that its numbers may remain stable, at least over short term, in both selectively logged forest and all but the smallest forest fragments; at some sites may in fact be more common in fragments and second growth than in undisturbed forest. Despite its apparent ability to survive even in fragmented forest, so little habitat remains in isolated range of race *taunayi* that this taxon should probably be monitored in the future. Populations experience lower seasonal fluctuations than do those of some professional ant-followers, which may explain its persistence in fragments. Species is regarded as an indicator of tropical lowland evergreen forest along Caribbean slope of Central America, and in Chocó lowlands, N South America and both N & S Amazonia.

### 3. Plain-winged Woodcreeper

#### *Dendrocincla turdina*

**French:** Grimpard grive **German:** Einfarb-Baumsteiger **Spanish:** Trepatroncos Turdino  
**Other common names:** Thrush-like Woodcreeper, Plain Woodcreeper

**Taxonomy.** *Dendrocolaptes turdinus* M. H. K. Lichtenstein, 1820, no locality = Bahia, Brazil. Forms a superspecies with *D. fuliginosa*, and often regarded as conspecific. Race *atirostris* of latter considered by some authors to be better placed with present species on basis of vocalizations and presence of crown streaking. Birds from S of range named as race *enalincia*, but characters on which description based are obscured by marked individual variation in both size and plumage coloration throughout species’ range. Monotypic.

**Distribution.** E & SE Brazil (from E Bahia S along coast to N Rio Grande do Sul, extending inland to S Goiás, W Paraná and W Santa Catarina) and E & C Paraguay and NE Argentina (Misiones and NE Corrientes).

**Descriptive notes.** 19–21 cm; 31–45 g (Brazil), female 29 g (Paraguay). Medium-sized woodcreeper with short, straight bill. Plumage uniformly olive-brown, apart from faint buff shaft streaks on crown, pale buff throat, and slightly more rufescent rectrices, uppertail-coverts and distal remiges; wing-linings ochraceous buff; iris brown; bill grey to blackish, with lower mandible often paler; legs and feet brown to grey. Differs from *D. fuliginosa* in having brown wings largely colorous with body, tail not so rufescent. Female like male in plumage, but marked variation in size suggests sexual dimorphism. Juvenile undescribed. **Voice.** Apparent song a monotonous series lasting 1 minute or more, comprising “tik”, “kik” or “keek” notes at same pitch, c. 3 notes per second, with amplitude varying seemingly at random; various calls described as “cha-a-a-a” rattle, “chahh” hiss, and “stau”. Both supposed song and “stau” call different from comparable vocalizations of *D. fuliginosa*.

**Habitat.** Primarily lowland humid forest, less frequently cloudforest of lower montane zones; also, follows gallery forest well into *cerrado* region. Occupies both interior of mature forest and older second growth, sometimes edges. Mainly frequents forest understorey and mid-levels. Largely restricted to tropical lowlands, with lower numbers in subtropical zone of foothills, to 1250 m.

**Food and Feeding.** Mainly insectivorous. Coleoptera, Hemiptera, and many unidentified items found in one stomach from Brazil (Espírito Santo); small beetles and ants found in another study. Forages chiefly in association with army-ant swarms (generally *Eciton burchelli*, occasionally *Labidus praedator*), using perches at low to medium heights. Prefers near-vertical perches, c. 15 cm in diameter and 2–3 m above ground when over ants; less often on smaller trunks down to 0.3 m or up to 9 m; rarely uses trunks with diameter more than 25 cm. Occasionally gleans prey from surfaces when over ants, but prefers to sally to ground, foliage, trunks or other substrates; sometimes captures prey in mid-air. Moderately aggressive towards same species and others when over ants, occasionally supplanting smaller species; is itself supplanted by larger ones, e.g. *Dendrocolaptes platyrostris*. Also a regular attendant in mixed-species flocks, especially those led by Cinerous Antshrike (*Thamnomanes caesioides*) in N part of range. Generalized foraging habits may be an adaptation for survival near S limit of army-ant occurrence, where inactivity of ants during cold weather sometimes forces it to forage independently of them.

**Breeding.** In Brazil, nest with eggs in mid-Nov in São Paulo (where birds with limited moult and worn flight-feathers in Jul), singing in Nov–Jan in S Bahia and N Espírito Santo, and heard (presumably songs) in early Mar in N Rio Grande do Sul; birds in breeding condition in Nov in

Paraguay. Nest in cavity in tree trunk, lined with leaves and stems; one in São Paulo consisted of lining of wood chips located within cavity 1.5 m up in trunk. Clutch 2 white eggs, average  $26 \times 19$  mm; incubating bird regularly left to take breaks away from nest; young apparently raised by a single parent, presumably female. Several ringed birds recaptured after 2 years, and one after nearly 5 years.

**Movements.** Resident throughout most of range, including W edge, but the few records from Rio Grande do Sul all in Oct-Mar, so that retreat from S fringe of range during austral winter possible. **Status and Conservation.** Not globally threatened. Despite obvious declines following disappearance of vast expanses of its Atlantic Forest habitat, remains fairly common to common in extensive tracts that still exist in Brazilian part of range. Probably most severely depleted in N part of range, where little forest remains, but even there is relatively common in larger tracts of native forest, e.g. Sooretama Biological Reserve and adjacent Linhares Natural Reserve. Rare at fringes of range in Paraguay and N Rio Grande do Sul; uncommon in NE Argentina. Occurs both in primary forest and in older second growth, and seems to be only moderately affected by human disturbance; common at some sites in both selectively logged and second-growth forest. The species persisted, in diminished numbers, for at least several years in a small fragment of forest from which army ants had disappeared, but a study at same site 15 years later failed to find it.

**Bibliography.** Aleixo & Galetti (1997), Aleixo & Viellard (1995), Anciães & Marini (2000b), dos Anjos *et al.* (1997), Belton (1973, 1984), Berla (1944), Brooke (1983), Cory & Hellmayr (1925), Davis (1945, 1946), Esteban (1948), Hayes (1995), Hellmayr (1908), Ihering (1898), Lopes *et al.* (1980), Marini *et al.* (1996), Narosky & Yzurieta (1993), Oniki (1981), de la Peña (1988), Pinto (1932, 1935, 1947, 1978), Reinert *et al.* (1996), Ridgely & Tudor (1994), do Rosário (1996), Schubert *et al.* (1965), Scott & Brooke (1985), da Silva (1996), Storer (1989), Stotz (1993), Stotz *et al.* (1996), Willis (1979c, 1982d, 1983c).

## 4. Tawny-winged Woodcreeper

### *Dendrocincla anabatina*

**French:** Grimpar à ailes rousses

**Spanish:** Trepatroncos Sepia

**German:** Lohschwingen-Baumsteiger

**Taxonomy.** *Dendrocincla anabatina* P. L. Sclater, 1859, Omoa, Cortés, Honduras.

Has been suggested as being sister-species of *D. tyrannina*. Race *saturata* merged with nominate by some authors, but darker, more olive upperparts and allopatric distribution support recognition as separate race. Three subspecies recognized.

#### **Subspecies and Distribution.**

*D. a. anabatina* P. L. Sclater, 1859 - Caribbean slope from S Mexico (SE Veracruz and N Oaxaca E to S Quintana Roo) S & E to NE Nicaragua.

*D. a. typhla* Oberholser, 1904 - Yucatán Peninsula (E Yucatán, N Campeche, N Quintana Roo).

*D. a. saturata* Carriker, 1910 - Pacific slope of Costa Rica (S from Gulf of Nicoya) and W Panama (W Chiriqui).

**Descriptive notes.** 17-19 cm; male 34-42 g, female 29-39 g (*anabatina*). Medium-sized woodcreeper with straight bill, relatively short tail, slightly crested appearance (shaggy nape). Nominant race has brown head with buffy supercilium, dark olive-brown crown, nape and back; cinnamon-rufous to rufous-chestnut uppertail-coverts and tail; wing-coverts like back, but remiges tawny with dusky tips, forming conspicuous panel in wing; throat pale buff, underparts light olive-brown, blending towards cinnamon on belly and undertail-coverts; iris yellowish-brown to grey, orbital skin grey; bill slaty grey, dark brown or black, lower mandible grey or bluish; legs and feet dark blue-grey to blackish. Sexes similar. Juvenile is like adult, but throat duller, supercilium broader and more diffuse, eyes sometimes white. Race *typhla* is more pallid than nominate, especially below; *saturata* is darker, more olivaceous, above, with duller centres of remiges. **Voice.** Song an extended rattle lasting to 70-80 seconds that sometimes stutters or changes cadence or quality, and occasionally ends in doubled "cheeu" "cheeu", resembles song of *D. fuliginosa*; calls a plaintive "squirrel", "deyeew", "cheeuw" and "tchee-u".

**Habitat.** Humid evergreen forest; also mangroves and, on Yucatán Peninsula, semi-deciduous forest. Primarily mature forest and older second growth, but occasionally in edge situations and semi-open areas. Frequents undergrowth, usually quite close to ground. Mainly lowlands to 500 m, but ascends foothills to 1200 m in Mexico, occasionally 1500 m in Costa Rica.

**Food and Feeding.** Largely insectivorous, but small vertebrates (especially lizards) and some vegetable matter also taken. Prey taken when feeding over army ants were earwigs (Dermaptera), grasshoppers (Acrididae), moths, spiders, and ants other than army ants. Stomachs contained principally spiders, beetles, wasps, orthopterans, caterpillars, various types of ant, hemipteran bugs, and small quantities of other types of prey, including scorpions, pseudoscorpions, snails; seeds and pulp from both *Ficus* and *Psychotria* found in some stomachs. An obligate ant-follower, regularly checks inactive bivouacs, and routinely forages at more than one swarm on same day. Forages low over ant swarms (both *Eciton burchelli* and *Labidus praedator*), usually perching 0-3 m above ground on near-vertical trunks and branches, often those of small diameter. Regularly seen in same flocks as *D. homochroa*. Captures prey chiefly by short sallies to ground or low foliage, less frequently to other substrates and to open air. Apparently excluded from some sites by larger, more aggressive Ocellated Antbird (*Phaenostictus mcleannani*). Usually seen singly or in twos, and often highly aggressive towards its own and other species. Foraging behaviour away from army ants poorly known, but apparently a regular follower of Squirrel Monkey (*Saimiri oerstedii*) troops in S Costa Rica. Both "anting" behaviour and "wing-flashing" have been noted.

**Breeding.** Newly hatched young in late May and dependent juvenile in mid-Jul in Belize; nest preparation beginning late Feb, eggs laid early Mar to Jun, hatching from May and nestlings to late Jul in Costa Rica; specimens in breeding condition late Feb to May in S Mexico, Belize, Guatemala and Honduras; male with small testes and moulting wing and tail in mid-Jul in Yucatán Peninsula; apparently one brood per season. Seen in pairs only in Nov-Jan in Costa Rica, suggesting short-term pair-bond. Nest built by one adult, presumably female, from mosses, fibrous rootlets, strips of papery bark, and lichens, generally within low (1.5-6 m up) cavity of bamboo pole, stump or root cluster; often uses natural cavity but occasionally old hole of woodpecker (Picidae). Clutch 2 white eggs; incubation and care of young apparently by only one parent, presumably female; incubates for 60-70% of day, in sessions of 15-90 minutes, with breaks of 10-40 minutes; incubation period 20-21 days; chick hatches with eyes closed, pink skin, yellow mouth-linings, sparse grey down; food items brought to nests in Costa Rica mostly insects, small at first, larger as young grew, numerous small lizards representing bulk of nestling diet in mass,

though not number; nestling period 24 days. Unusual record of one bird rearing a *Lepidocolaptes souleyetii* from egg to fledging after usurping nest of its parents. Nest success in Costa Rica 57% overall, but only 33% for nests found before last egg laid.

**Movements.** Resident; individuals recaptured at same site in Belize both in same and in subsequent seasons, reflecting sedentary nature. Five individuals captured and later released at a nearby site in Mexico all returned to their original territories.

**Status and Conservation.** Not globally threatened. Fairly common to common within humid forest over most of range from Mexico S to Costa Rica, but rare in deciduous forest in Yucatán Peninsula; less common at upper elevations, and uncommon to rare at margins of range in Oaxaca (Mexico), NE Nicaragua and W Panama. Although ant-following species in general are relatively intolerant of forest fragmentation, and present species in particular considered by some authors to be sensitive to human disturbance, individuals captured in overgrown fields in Belize and in Yucatán Peninsula suggest some tolerance of disturbance. It has even been speculated that this species could expand its range in S because it is less sensitive to disturbance than are aggressive thamnophilid antbirds that now exclude it from some sites. A study in S Mexico estimated size of home range at 2 ha. Considered an indicator of tropical lowland evergreen forest of Caribbean slope.

**Bibliography.** Anon. ## 5. White-chinned Woodcreeper

### *Dendrocincla merula*

**French:** Grimpar à menton blanc

**Spanish:** Trepatroncos Barbiblanco

**German:** Weißkinn-Baumsteiger

**Taxonomy.** *Dendrocolaptes Merula* M. H. K. Lichtenstein, 1820, "Cayenne".

Formerly included the taxon *meruloides*, now considered to be closer to *D. fuliginosa*. Races N of R Amazon and E of R Negro (nominate, *obidensis*) possibly constitute a separate species based on differences in vocalizations, size and iris colour; more work needed. Seven subspecies recognized.

#### **Subspecies and Distribution.**

*D. m. bartletti* Chubb, 1919 - W Amazonia and upper R Orinoco drainage, both N & S of R Solimões, from C Venezuela and C Colombia, S to E Ecuador, E Peru, N Bolivia and W Amazonian Brazil (E to R Negro and R Madeira).

*D. m. merula* (M. H. K. Lichtenstein, 1820) - the Guianas and adjacent N Brazil (E of R Branco in Roraima and N Pará).

*D. m. obidensis* Todd, 1948 - Amazonian Brazil, along N bank of Amazon, from R Negro E to Amapá. *D. m. remota* Todd, 1925 - E Amazonian Bolivia (N Santa Cruz), probably also adjacent Brazil (NW edge of Pantanal).

*D. m. olivascens* J. T. Zimmer, 1934 - S Amazonian Brazil, S of Amazon, from R Madeira E to R Tapajós.

*D. m. castanoptera* Ridgway, 1888 - S Amazonian Brazil, S of Amazon, from R Tapajós E to R Tocantins.

*D. m. badia* J. T. Zimmer, 1934 - SE Amazonian Brazil, S of Amazon, from R Tocantins E to Maranhão.

**Descriptive notes.** 16-21 cm; male 28-54 g, female 29-54 g (much of Amazonia), male average 57 g, female 49-5 g (Manaus). Geographic variation in size significant; birds from SE Peru slightly larger than others, and birds along N bank of Amazon R (E of R Negro) substantially so. Medium-sized woodcreeper with relatively short, straight bill, uniform-looking plumage. Nominant race is almost entirely dark reddish-brown, with wing-coverts, remiges and tail slightly more rufescent; tips of inner webs of outer primaries dark brown; narrow stripe of white to yellowish from chin to lower throat sharply defined (often difficult

to see in field); underparts dark olive-brown, blending to dark rufous on undertail-coverts; underwing-coverts pale chestnut; iris reddish-brown to brown; bill brownish to black, lower mandible variably black to brown, grey, greenish, even pale yellowish to nearly white, sometimes with black tip; legs and feet bluish, olive, grey or brownish. Differs from *D. fuliginosa* mainly in lacking facial striping, instead appearing plain-faced apart from pale throat. Sexes similar, female may average slightly smaller. Juvenile has less contrasting throat dirty white or dingy buff, generally darker underparts, often entirely dark bill apart from obvious gape-flanges. Race *obidensis* similar to nominate in coloration, but significantly larger; remaining subspecies all generally paler, both above and below, with *remota* the palest and *olivascens* more olive overall; both *castanoptera* and *badia* again more rufescent, especially the latter, which also has a larger, whiter throat-stripe; *bartletti* differs by having dusky tips to primaries and outer secondaries; colour and extent of pale throat, and pattern of the primaries vary geographically; also eye colour, grey or blue-grey to bluish in most of range, but reddish-brown to brown in races *merula* and *obidensis*; probably more complex than this, because both brown and grey eyes noted in Roraima and Orinoco region, and one bird with brown eyes collected in northern Mato Grosso. **Voice.** Calls often heard near ant swarms, but songs poorly known; both vary geographically. Most frequent vocalization a multi-note chatter call, often given at ant swarms, usually 2-4 notes, described as "dit-it-it-it" or "tat-at-at" over most of range, but piercing "deet-eet-ee" in N Amazonia E of R Negro. Song in Manaus area (Brazil) a series of 6-9 loud, whistled notes described as "kew, kew, kew, kew, kew", but over most of range apparently lower in frequency and described as "we, wi, di, dit", or "wi-wid-wid-di" in SE Colombia, and in some places an ascending whistle of 2-3 notes. Other calls include sharp "spee" notes in Manaus area, growling "chauhhh", long rattle at 4-5 notes per second (i.e. slower than *D. fuliginosa*), quiet "wi-i-i-i-ih" rattle, also "tsiriRIT" possibly as warning call.

**Habitat.** Primarily humid forest, both *terra firme* and on floodplains; also forests on sandy soils in Colombia and at some sites in Brazil, and occasionally gallery, riverine or flooded forests. Prefers open understorey of interior of mature forest, less frequently subcanopy, older second growth and edges; occasionally in denser vegetation around streams, young second growth, bamboo thickets, or fringes of *várzea* forest. Largely restricted to forest undergrowth, using lower strata than *D. fuliginosa* occurring at same sites. Exclusively lowlands, generally below 300 m, occasionally to 500-600 m.

**Food and Feeding.** Diet consists largely of arthropods, but small vertebrates occasionally taken. Stomach contents from one site in N Bolivia mostly Hymenoptera and beetles (each comprising 33% of diet), with fewer spiders (19%) and Orthoptera (14%); other items rarely taken. Stomachs from other sites in N Bolivia and from E Peru contained primarily orthopterans, spiders and ants, with lesser numbers of beetles, cockroaches (Blattodea), bugs, vertebrates; those from Amazonian Brazil contained Hemiptera, Coleoptera, Blattaria, Isoptera, and even Odonata. Comparison of stomach contents with prey flushed by army ants revealed orthopterans are taken preferentially, with cockroaches and, especially, Hymenoptera avoided. May select prey of small to moderate size, possibly larger than taken by some other dendrocolaptids; 21% of items smaller than 7 mm, 65% were 8–16 mm, and 14% over 16 mm. Substantial overlap with other woodcreepers and several ant-following antbirds (Thamnophilidae) in both type and size of prey taken; however, this and other ant-following dendrocolaptids may take smaller items than antbirds, in relation to bill size, because they have more difficulty in removing appendages before eating prey. Prey observed taken over swarming army ants include, in decreasing order of abundance, cockroaches, spiders, ant larvae, centipedes (Chilopoda), scorpions, crickets (Gryllidae), grasshoppers (Acrididae); beetles, moths, skippers (Hesperiidae), whipscorpions (Amblypygi) and lizards all taken only on occasion. An obligate ant-follower, forages mostly over *Eciton burchelli*, also regularly over *Labidus praedator*; may visit multiple ant swarms on same day, and monitors inactive colonies; radio-tracked female with nestling routinely travelled over 300 m between ant swarms, suggesting that movements of over 500 m from nest to foraging sites perhaps not uncommon. Typically, 1–2 individuals present at swarms in Brazilian Amazon, but up to 7–8 seen at swarms in SE Peru; larger groups probably involve wandering immatures, aggregates of solitary birds, or females with young. Perches lower and often on slimmer trunks than do other woodcreepers, rarely more than 3 m above ground, often using trunks with diameter less than 15 cm. Foraging methods vary depending on presence of large antbirds such as Black-spotted Bare-eye (*Phlegopsis nigromaculata*). In Brazil, nearly 90% of all foraging is within 1 m of ground in absence of *Phlegopsis* near Manaus, where regularly remains relatively motionless on slimmer and more angled perches, but near Belém, where *Phlegopsis* present, only 58% of foraging below 1 m, birds move about more over ants, and they forage mostly from larger (6–15 cm diameter), near-vertical trunks. Suggested correlation between body size of these woodcreepers and presence of large antbirds not supported by small size of birds in Roraima, where large antbirds are absent. Rarely hitches far up trunks, instead flying between perches. Most prey taken by rapid sallies to ground, followed by return to perch; sallies occasionally to foliage, rarely to other substrates. Seldom picks or gleans prey from trunks or foliage. Has been observed to perform “anting”, but rarely flicks wings to flush prey. Highly aggressive towards both conspecifics and other species over ants, usually supplanting smaller species and being supplanted by larger ones; dominant over *D. fuliginosa*, often excluding it from foraging low over swarms, or forcing it to forage away from them. Rarely seen away from ants; at such times moves rapidly and silently through understorey, apparently in search of new swarms. Rarely follows mixed-species flocks away from ants. Radio-tracked birds observed to forage also in association with herds of peccaries (*Tayassu pecari*), which flush prey much as do swarming ants; one individual even seen perched atop hindquarters of a peccary.

**Breeding.** Little known. Birds in breeding condition in Feb–May in NW Brazil, E Colombia and S Venezuela, in late Jun in NE Amazonian Brazil (Amapá) and in mid-Aug in S Amazonian Brazil (Mato Grosso), and in non-breeding condition in early Oct in NE Amazonia; fledged juveniles of *obidensis* mid-Jul to mid-Oct, but juvenile specimens of other races mostly May–Jul; in W Amazonia, juveniles appear at ant swarms in Dec–Jan (SE Peru) and adults in moult in Oct–Apr; birds moulting in Apr in upper R Orinoco region and in worn plumage in Sept in French Guiana, suggest breeding during dry season; more work needed to confirm geographical component to variation in season. Pair-bond apparently brief; male and female associate irregularly, and for only c. 1 month, but may investigate nesting cavities together. Nest undescribed, apparently in cavity. No details on clutch size and eggs; DNA analysis revealed that female alone raises young and associates with them after fledging; male lacks brood patch, and not observed to attend young; fledglings remain with parent for 3 months (until late Jan or early Feb near Manaus), but often stay in area longer (two still present in following May); one, rarely two, dependent young encountered with single parent. Nest predation suggested as less than 80% over a breeding season of 3–6 months. Adult survival relatively high, with average annual survival 71% over 3-year period (10 of 26 birds resighted 3 years after initial capture); one bird recaptured at another site after 4 years.

**Movements.** Resident. Some movement within sites; even “settled” birds move over areas 2–3 km across; the sexes have overlapping territories.

**Status and Conservation.** Not globally threatened. Locally common, but apparently uncommon over much of range. Abundance may be depressed through competition over ants by larger thamnophilids; densities possibly lower in S & W Amazonia where *Phlegopsis* and *Rhegmatorhina* present, but fairly common to common in absence of those species near Manaus and at sites in both Rondônia and Roraima; uncommon in Amapá and Guyana in absence of large antbirds, but rare at Belém in their presence. Only one record from Surinam, in 19th century; uncommon in French Guiana and N Bolivia; scarce and possibly local in Venezuela; fairly common to common in W Amazonian Brazil and adjacent Peru; uncommon in NW Mato Grosso, but quite rare at well-worked Alta Floresta (NC Mato Grosso); rare in NE Ecuador. Density at site in floodplain-forest in SE Peru 16–22 birds/100 ha, with average home range over 64 ha; at Manaus 2–5 birds/100 ha considered an annual low, with 3–6 birds/100 ha representing peak (post-breeding) density. Like other obligate ant-followers, highly sensitive to fragmentation and disturbance of mature forest, all but disappearing from fragments up to 100 ha in size, and apparently requiring 200–400 ha to survive; birds experimentally introduced into 10-ha fragments lacking army ants left within 48 hours, many sooner, and capture rates dropped effectively to zero in fragments smaller than 10 ha. Gaps shown not to be an insurmountable barrier, despite significantly reducing bird movement; marked birds crossed 75–100 m of open space between fragments and continuous forest (not only to abandon fragments, but also occasionally to visit them when scouting for swarming ants). Trapped while moving through second growth dominated by both *Vismia* and *Cecropia* in approximately equal numbers, and apparently able to use regenerating forest to move between patches of better habitat. Often abandons ant-swarms that move into second-growth, and always those that enter clearings. Even relatively low levels of selective logging may have significant impact on this and other dendrocolaptids. An indicator species for tropical lowland evergreen forest in both N & S Amazonia.

## 6. Ruddy Woodcreeper

### *Dendrocicla homochroa*

**French:** Grimparr roux **German:** Rostkappen-Baumsteiger **Spanish:** Trepatroncos Rojizo

**Taxonomy.** *Dendromanes homochrous* P. L. Selater, 1859, Teotalcingo, Oaxaca, Mexico.

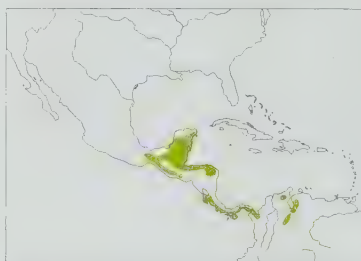

Race *acedesta* merged with nominate by some authors, on grounds that size variation is clinal. Birds on Caribbean slope in Costa Rica apparently belong to former race, but substantiation required. Four subspecies recognized.

#### **Subspecies and Distribution.**

*D. h. homochroa* (P. L. Selater, 1859) - Caribbean and Pacific slopes of S Mexico (N & NE Oaxaca, Yucatán Peninsula), S & E to Belize, Guatemala, El Salvador (one site), Honduras and NE Nicaragua. *D. h. acedesta* Oberholser, 1904 - Pacific slope from SW Nicaragua S to W Panama; also on Caribbean slope in N two-thirds of Costa Rica.

*D. h. ruficeps* P. L. Selater & Salvin, 1868 - C & E Panama (E from E Chiriqui) and locally in adjacent NW Colombia (N Chocó).

*D. h. meridionalis* Phelps, Sr. & Phelps, Jr., 1953 - N Colombia and NW Venezuela (lower slopes of Perijá Mts and Cordillera de Mérida).

**Descriptive notes.** 17.5–20.5 cm; male 34–43 g, female 27–39 g (Yucatán S to Guatemala), male average 45 g, female 37 g (Panama). Medium-sized woodcreeper with straight bill, short tail, large head; hammer-headed appearance imparted by conspicuously ruffled nape. Rather uniformly dark rufous to chestnut-brown above, brighter and more rufescent on crown, no obvious facial markings apart from greyish lores and eyering; wings, uppertail-coverts and tail rufous-chestnut, primary tips dusky; throat paler, cinnamon-buff to tawny-ochraceous, underparts rufous-brown, becoming paler on belly, more rufous on undertail-coverts; underwing-coverts light rufous; iris reddish-brown to light chestnut-brown; bill usually dusky brownish, greyish or dull flesh-coloured with blackish tip, sometimes all black; feet pale greyish to greyish-brown. Sexes similar. Juvenile is virtually identical to adult, but throat and belly slightly more rufescent. Race *acedesta* is on average larger, darker and more olive than nominate, throat and belly less conspicuously paler; *ruficeps* is slightly larger than previous, with bill heavier, overall coloration slightly paler; *meridionalis* has crown darker chestnut, back darker and more olive-brown than other races. **VOICE.** Quiet and rarely heard. Song a 2–5–4 second rattle, churring or slightly slurred, that slows or descends towards end; similar in quality to that of congeners, especially *D. anabatina*, but shorter, and notes delivered more rapidly. Calls include churring, a squeaky “quink” or “peach”, and a nasal, descending “deeeeah” or “tee tee eu” often quavering at end.

**Habitat.** Humid and deciduous lowland forest; evergreen cloudforest into upper tropical and, occasionally, lower subtropical zones; semitropical-deciduous forest and gallery forest in drier regions; less commonly “broken pine ridge” areas in Belize. Occasionally moves from mature forests and older second growth into nearby edges, semi-open areas, and trees within clearings. May to a degree be specialized on foraging on mossy trunks in upland forest. Occurs in both lowlands and foothills from sea-level to 1800 m, but generally most common in foothills between 300 m and 1200 m. Commonest below 1000 m in Mexico, Belize and Guatemala, but occurs at 1300–1550 m at N limit of range (Oaxaca, in Mexico); lowlands in Honduras, Costa Rica and Panama, but apparently most common in these countries on lower slopes of foothills (300–900 m, occasionally to 1350–1800 m); one of only two obligate ant-followers above 1200 m in W Panama. Restricted to foothills and hill country in Colombia, where poorly known; largely in foothills in Venezuela, where mostly below 450 m but occasionally to 1800 m (at least historically).

**Food and Feeding.** Diet largely arthropods. Stomach contents reveal prey similar to that seen taken over swarming army ants. Important prey include spiders, cockroaches (Blattodea), grasshoppers (Acrididae), beetles and their larvae, and caterpillars; various types of ants and wasps also taken in small quantities. High degree of dietary overlap with *D. anabatina*, but takes fewer spiders. Rarely seen away from army-ant swarms, where usually present singly or in twos, rarely threes. Forages over both *Eciton burchelli* and *Labidus praedator*, more often the former. Typically, forages from perches 2–10 m above ground, both on larger trunks and at higher levels than *D. anabatina*, and often present in same flocks; prefers larger, more mossy trunks than congener. May descend to perches within 1 m of ground in semi-open situations. Perches on near-vertical trunks in undergrowth, and either pecks prey from mossy trunks or sallies to ground, foliage or other substrates; pecking more common than in any other member of genus. Generally sallies downwards to targets within 1 m, less frequently in upward direction or to distances to 5–6 m. Sometimes forages among epiphytic mosses and bryophytes. Apparently dominant over *D. fuliginosa*; subordinate to and less pugnacious than *D. anabatina*. Often quiet and inconspicuous. Regularly flicks wings, but wing-flashing not recorded. So rarely encountered away from ant swarms that virtually nothing is known of behaviour at such times; has been seen moving singly through lower levels of open forest searching surfaces of trunks and limbs, and occasionally joins mixed-species flocks.

**Breeding.** Season Apr–Jun in Costa Rica; nests with eggs in Jun in Belize; birds in breeding condition in late May to mid-Aug in Yucatán Peninsula, Mar–Jun in Guatemala, Mar in Panama and Apr–May in Colombia. Nest of bark and fibres, built in cavity of stump, tree or palm trunk 0.6–5 m above ground; deep cavities first filled with moss or leaves. Clutch 2–3 white eggs.

**Movements.** Largely resident. Reports of vagrants at La Selva Biological Station, in Costa Rica, and Barro Colorado I, in Panama, suggest wandering from higher elevations; may likewise be nomadic in dry NW part of Costa Rica.

**Status and Conservation.** Not globally threatened. Generally uncommon to fairly common throughout N part of range (Mexico S to E & SW Costa Rica), but less common and more local in El Salvador (common at one site), NW Costa Rica, Panama, and South America; in S portion of range, apparently more common in N parts and in foothills of S Central America, and possibly more common in Venezuela than in Colombia, but believed to be declining due to loss of forest. Reports of presence on islands off Yucatán Peninsula (e.g. Cozumel I) probably the result of mislabelled specimens. Present only in mature forest at sites in Belize and Yucatán Peninsula, where *D. anabatina* was found in both scrub and mid-successional growth; occasionally followed ant swarms from

forest into adjacent shade coffee plantations in W Panama, but never wandered far from true forest and never entered coffee grown in sunlight. Appears to be highly sensitive to loss and fragmentation of mature forest; even within suitable habitat numbers seem to fluctuate substantially, this possibly contributing to local extinction at marginal sites. That birds began to return to unburned, regenerating forest only 18 months after hurricane "Gilbert" hit Yucatán Peninsula, however, suggests that some populations can exist in relatively degraded forest. Considered an indicator species for tropical lowland evergreen forest in N South America.

**Bibliography.** Anon. (1998a), Binford (1989), Blake (1953, 1958), Carriker (1910), Cory & Hellmayr (1925), Edwards (1972), Griscom (1926), Hartman (1961), Hilty (2003a), Hilty & Brown (1986), Howell & Webb (1995a), Karr (1971b, 1982a, 1982b), Karr, Robinson *et al.* (1990), Klaas (1968), Kricher & Davis (1998), Land (1963, 1970), Lynch (1991), Meyer de Schauensee (1964, 1966), Meyer de Schauensee & Phelps (1978), Miller *et al.* (1957), Monroe (1968), Nadkarni & Matelson (1989), Paynter (1955), Peterson & Chalif (1973), Phelps (1944), Phelps & Phelps (1953b, 1963), Puebla (2001), Puebla *et al.* (2002), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Roberts *et al.* (2000), Rodner *et al.* (2000), Russell (1964), Salvin (1870), Slud (1964, 1980), Smith (1966), Smith & Paynter (1963), Stiles (1983b, 1985), Stiles & Skutch (1989), Storer (1961), Stotz *et al.* (1996), Sturgis (1928), Sutton (1951a), Thurber *et al.* (1987), Underwood (1896), Van Tyne (1935), Wetmore (1944, 1972), Willis (1960a, 1983c, 1986), Willis & Oniki (1988c).

## Genus *DECONYCHURA* Cherrie, 1891

### 7. Long-tailed Woodcreeper

#### *Deconychura longicauda*

**French:** Grimpur à longue queue

**Spanish:** Trepatroncos Colilargo

**German:** Langschwanz-Baumsteiger

**Taxonomy.** *Dendrocincla longicauda* Pelzelin, 1868. Borba, Marabitanas, Barra do Rio Negro = Manaus, Brazil.

Races *typica*, *darienensis* and *minor* sometimes considered to constitute a separate species, with small size and vocal characters suggesting possibly closer relationship to *D. stictolaema* than to Amazonian populations of present species. Birds from NW Colombia (Córdoba) possibly intergrades between *darienensis* and *minor*. Amazonian races more uniform morphologically, but song of nominate differs so markedly that remaining three may warrant species status as *D. pallida*, with *zimmeri* and *connectens* as races. Populations in Andean foothills of E Ecuador apparently belong to *connectens*, but adjacent lowland birds possibly race *pallida*; further study required. Seven subspecies recognized.

#### **Subspecies and Distribution.**

*D. l. typica* Cherrie, 1891 - S Honduras (isolated site), and NC & SW Costa Rica E to C Panama (Chiriquí, Veraguas).

*D. l. darienensis* Griscom, 1929 - E Panama and adjacent NW Colombia.

*D. l. minor* Todd, 1919 - NC Colombia (Santander).

*D. l. longicauda* (Pelzelin, 1868) - the Guianas and N Brazil, N of Amazon, from R Negro E to Amapá.

*D. l. connectens* J. T. Zimmer, 1929 - W & NW Amazonia, N of Amazon, from E Colombia and S Venezuela S to E Peru (W of R Ucayali) and NW Brazil (upper R Negro).

*D. l. pallida* J. T. Zimmer, 1929 - S Amazonia, S of Amazon, from E & SE Peru (E of R Ucayali) E to C Amazonian Brazil (E at least to R Tapajós) and S to N Bolivia and N Mato Grosso.

*D. l. zimmeri* Pinto, 1974 - SE Amazonian Brazil, S of Amazon, from at least R Tocantins (possibly from R Tapajós) E to Maranhão.

**Descriptive notes.** 17-18.5 cm (Panama), 19-22 cm (South America); 19-26 g (Costa Rica, Panama), 25-28 g (S Venezuela, Surinam), mean 29 g (Manaus). Medium-sized, slim woodcreeper with long wings and tail, relatively long neck, large "scruffy-looking" head, slim straight bill of medium length. Nominative race is largely olive-brown, with darker crown and nape both finely streaked buff, whitish to rich buffy lores and narrow but well-defined supercilium; back virtually unmarked, rufous-chestnut wings, uppertail-coverts and tail, dusky primary tips; throat whitish-buff to ochraceous; breast streaked buff, markings

more spot-like nearer throat, remaining underparts dull olive-brown and unmarked, becoming rufous on undertail-coverts; axillaries and underwing-coverts cinnamon-rufous; iris hazel to dark brown; upper mandible dark brown to blackish, lower mandible brownish-grey to bluish, tip sometimes black; legs and feet brown or bluish-grey to black. Distinguished from very similar *D. stictolaema* mainly by larger size, longer bill, more streak-like breast markings, less rufous on rump. Female is on average significantly smaller than male. Juvenile is similar to adult, but throat with brownish scaling, breast spots larger and less distinct. Relative to nominate, markings on throat and breast of both *connectens* and *pallida* paler and less ochraceous (becoming yellowish in *pallida*); those on breast of *connectens* more spot-like, those of *pallida* slimmer and more streak-like; *zimmeri* is more olivaceous, with throat, supercilium and breast markings even paler and more yellowish than *pallida*. Members of "typica subspecies-group" significantly smaller than nominate, with more spot-like markings on breast; taxa within group differ slightly in coloration and possibly size. **VOICE.** Three markedly different song types, each given at infrequent intervals throughout the day. Songs in Amazonia comprise series of clear whistles delivered slowly; nominate gives a series of 6-8 similar "chueeet" notes largely on one pitch, but each rising slightly at end; that of *pallida* (and apparently *connectens* and *zimmeri*) a clearly descending series of 8-12 shorter, sharper whistles, initial ones remaining on same pitch, but those later in song gradually becoming upward-inflected, "deee, deee, deee, deee, dueet, dueet, duu-eet, duu-eet, duu-eet". Song in Costa Rica very different, a weakly chirping "chih, chih, chip, chip, chip, chih, chih, chih..." trill that first speeds up, then slows, reminiscent of trill or rattle of *D. stictolaema*. Calls largely undescribed; in response to tape playback, nominate gives songs with more twitery notes, but members of "*pallida* group" give a constant chattering interspersed with occasional songs; when alarmed may repeat a harsh series of rapid, low trills at a rate of ca. 3/sec.

**Habitat.** Humid forest. In Amazonia, generally in *terra firme* and floodplain forests, less frequently in *igapó* or swamp-forest; in montane evergreen forest along slopes of Andes. Has been recorded in

dry or "semi-deciduous" forest in NW Bolivia. Generally interior of mature forest, sometimes at edge or in older second growth; captured in treefall gaps as often as within forest in Panama. Found in both lowlands and foothills, with Amazonian populations largely restricted to sites below 500 m, but possibly more common in foothills in Costa Rica, Panama and on E slope of Andes; at 400 m in Honduras; 400-1100 m on Caribbean slope in Costa Rica, but lowlands to 1400 m on Pacific slope; to 1400 m in Panama, where largely on Caribbean slope; to 1300 m in Colombia; on E slope of Andes found at 1200-1700 m in Ecuador and 685-1570 m in Peru. Populations occurring in lowlands and adjacent Andean foothills in some regions may represent different subspecies, for example, apparently *connectens* in foothills of E Ecuador, but possibly *pallida* in nearby lowlands.

**Food and Feeding.** Mainly, if not exclusively, insectivorous. Stomach contents in N Bolivia largely Hymenoptera (especially ants) and beetles (roughly 50% and 35% of diet, respectively, in one study), with a few bugs (less than 10%), and even fewer spiders, orthopterans, and other items; other studies found mainly beetles, but some orthopterans, a large cockroach (Blattodea), scorpions, cicadas, and other small insects. Apparently selects for prey of moderate size: 42% of items smaller than 7 mm, 57% were 8-16 mm, but less than 1% over 16 mm. Often forages singly, occasionally in pairs, with mixed-species flocks of both understorey and canopy; not strictly tied to flocks, and regularly switches between different ones. Usually seen as it hitches up slim to medium-sized trunks and vines from upper understorey to subcanopy (5-15 m up), less frequently lower, rarely up into canopy; forages in higher strata than used by *D. stictolaema*. Numerous reports of foraging closer to ground may reflect ease of observation. Sallies for flushed prey at times, but probably pecks or gleans much of its prey from trunks. Foraging overlap with larger *Xiphorhynchus* limited enough for peaceful coexistence with minimal aggression. Maintains overlapping home ranges, rather than exclusive territories. Rarely follows army-ant swarms. Occasionally observed "anting".

**Breeding.** Nest with eggs in Apr in Costa Rica; female with brood patch in mid-Aug and dependent young seen in early Nov in French Guiana; specimen in breeding condition in Feb in S Venezuela; a bird in N Brazil (Amapá) in late Jun was in non-breeding condition. One known nest, located in cavity c. 9 m up in dead trunk, cavity c. 1 m deep, lined with dry leaves. Clutch 2 white eggs, 22 × 17 mm; incubation at least by female, which seen to carry a dead leaf back to nest.

**Movements.** Chiefly resident. Reported as accidental visitor at La Selva Biological Station, in Costa Rica, suggesting some wandering, possibly from higher elevations.

**Status and Conservation.** Not globally threatened. Probably uncommon throughout most of Amazonian range, but even less common and more local in Central America. Shy nature and infrequent singing makes it inconspicuous and difficult to detect. Not seen in Honduras since first recorded, in 1953; apparently most common in Costa Rica in lowlands of SW; seems never to have been common in Panama, where most easily encountered in Canal Zone, and no recent records from W Chiriquí, where possibly extirpated. Only twice recorded in Surinam but fairly common to common in Guyana; generally uncommon to fairly common in Colombia and SE Peru, and fairly common to common at some Amazonian sites in Brazil; rare and local in Ecuador. Estimated densities in both upland forest in French Guiana and floodplain-forest in SE Peru 2 pairs/100 ha, and at a Panamanian site 5 pairs/100 ha; territory size at Peruvian site averaged 16 ha. Highly sensitive to habitat modification and requires nearly continuous forest; near Manaus, in Brazil, disappeared altogether in fragments of 1 ha in size, and numbers greatly reduced in those of 10 ha. Considered an indicator species for tropical lowland evergreen forest on Caribbean slope of Central America.

### 8. Spot-throated Woodcreeper

#### *Deconychura stictolaema*

**French:** Grimpur à gorge tachetée

**Spanish:** Trepatroncos Gorgipunteado

**German:** Kehlflücken-Baumsteiger

**Other common names:** Ecuadorian Woodcreeper (*secunda*)

**Taxonomy.** *Sittasomus stictolaemus* Pelzelin, 1868, Borba, Rio Madeira, Amazonas, Brazil. Possibly closest to "typica group" of *D. longicauda*, size and vocalizations of which more similar to present species than to Amazonian *D. longicauda*. Race *secunda* has been considered a separate species by some authors. Racial identity of birds from extreme E of range in Brazil (E of R Tocantins, to Maranhão) not known; tentatively included within nominate. Three subspecies recognized.

#### **Subspecies and Distribution.**

*D. s. secunda* Hellmayr, 1904 - W Amazonia from S Colombia and S Venezuela (S Amazonas) S to E Ecuador, NE Peru and NW Brazil (E to R Negro and R Madeira).

*D. s. clarior* J. T. Zimmer, 1929 - NE Amazonia, N of Amazon, in Brazil from R Negro E to Amapá, and French Guiana; populations in Guyana presumably this race.

*D. s. stictolaema* (Pelzelin, 1868) - S Amazonian Brazil, S of Amazon, from R Madeira E to lower R Tocantins and Maranhão, and S to N Mato Grosso.

**Descriptive notes.** 16.5-19 cm; male 14-22 g, female 13-17 g (Venezuela, Brazil). Small, slim woodcreeper with long tail, and slim, relatively short bill. Nominative race has crown and, to a degree, nape weakly streaked buff, pale lores inconspicuous, narrow buffy supercilium slightly more distinct; largely olive-brown above, darker on crown and back, blending to bright rufous-chestnut on lower back to uppertail-coverts; remiges dusky brown, blending to rufous towards tips of inner secondaries, and often with an area of bright cinnamon at shoulder; tail russet to deep chestnut; throat dull buff to olive-buff with darker speckling; dull olive-brown below, upper breast conspicuously marked with wedge-shaped buff spots, more streak-like at sides; wing-linings cinnamon-buff; iris dark brown; bill dark brown, lower mandible silvery to blackish-brown; legs and feet greyish-blue to brownish-grey. Distinguished from very similar *D. longicauda* mainly by smaller size, proportionately shorter bill, nearly unstreaked crown, more spot-like breast markings and, when evident, more extensively rufous rump; from *Glyphorhynchus spirurus* by larger and slimmer body and especially longer, slimmer bill. Female is like male. Juvenile plum-

Amazonia E of R Madeira (probably *transitivus*) song differs strikingly, comprising a series 4-4-5 seconds long of 7-8 clear whistles that descend slightly in frequency and cadence, "wip, whee, wheep, wheep, wheep, wheep, wheep, whip". In SE of range (*sylvellus*) song is a descending series of 8-10 evenly spaced "kwip" or "weep" whistles that accelerates slightly, especially at end. Vocalizations of *reiseri* include relatively soft "wit" or "weet" notes and disyllabic "whi-du" or "whe-doo", given in series both alone and in combination; in a single recording, apparently of full song, 17 almost evenly spaced notes in 5-second series began with 2 quiet "whi-du" notes followed by 8 "weet" notes that increased slightly in amplitude, then another disyllabic note, and finally a slightly decelerating series of 6 additional "weet" notes. Variety of additional calls include single "weep" or "weet" whistle at 1 per second and occasionally doubled (*sylvellus*), short dry rattle suggesting song of Long-billed Gnatwren (*Ramphococcyz melanurus*) (*sylvioides*), and dry rattling or "churring" on one pitch that either remains at same frequency and speed (*gracileus*) or begins quietly but increases markedly in intensity and sometimes speed near end (*sylvellus*); in some populations, rattles often accompanied by rapid wing-quivering.

**Habitat.** Variety of wooded habitats, mostly lowland evergreen forest, but populations in mountains range into montane evergreen forest and cloudforest, and those in drier regions occupy deciduous woodland, gallery forest, *caatinga* and *cerrado*; in Amazonia most common in *terra firme* forest, less frequent in seasonally flooded forests (both *várzea* and *igapó*). Typically in interior, canopy and edge of mature forest, less often older second growth and tree plantations, but in drier regions found in more scrubby habitats; in some places favours relatively open woodland, and recorded in pine (*Pinus*) woodland in Belize and mangroves in Panama. Primarily in lowlands and foothills below 1550 m; locally to 2000 m on Pacific slope in Mexico, and occasionally to 2200-2300 m in N Venezuela, Bolivian Andes and SE Brazil.

**Food and Feeding.** Diet comprises chiefly invertebrates (mostly arthropods), but vegetable matter occasionally taken. Detailed analysis of stomach contents in S Mexico revealed items typical of tree trunks, such as ants (especially *Pheidole*), a variety of small beetles, pseudoscorpions, and spiders, with fewer bugs (Hemiptera), termites (Isoptera), planthoppers (Homoptera), and trace quantities of other invertebrate groups (including snails); study in SE Brazil documented primarily adult and larval beetles (64%) and cockroach (Blattodea) egg cases (24%), with small quantities of bugs, flies, ants, planthoppers and termites. Elsewhere, additional items recorded as taken are small wasps, caterpillars, adult cockroaches, ant-lions (Myrmecoleonidae), eggs and pupae of various insects, ticks, and occasionally fruit seeds. Most prey small, usually less than 5 mm, but some items over 17 mm in length. Usually seen alone, sometimes in twos, and often with mixed-species flocks in both understorey and canopy; at some sites at least, leaves flocks during breeding season or during periods of wind or rain. Birds spent c. 60% of their time with flocks at site in SE Peru, where they moved between two or more flocks, with some individuals alternating freely between understorey and canopy flocks; present in up to 50% of flocks studied at site in NE Mexico, 56% of flocks at Amazonian sites, 33% at site in Venezuelan *llanos* and 67% in SE Brazil (varying with site, habitat and season). In one study, associated with troops of foraging lion-tamarins (*Leontopithecus chrysopygus*) for 3-9% (depending on season) of latter's activity period, one association lasting 35 minutes; sallied after insects dislodged by the primates. Regular presence at swarms of army ants (both *Eciton burchelli* and *Labidus praedator*) documented in S Mexico and SW Panama, mostly when with mixed-species flocks that joined swarms only briefly; shows no affinity for following army ants in Amazonia. Forages while rapidly hitching directly or spirally up trunks and large limbs. In SE Brazil, 30% of foraging was on branches (as opposed to trunks) and 36-86% on rough bark, sometimes explores branches covered with moss or lichen. Prefers trees larger than average size (mean girth at 1.3 m was 75 cm at site in SE Brazil), but high variance in trunk diameter may promote use of a wide variety of forest types; dead trees visited only rarely. Height preferences may differ by region, with birds typically foraging from mid-levels to canopy at some sites (averaging 8.5 m above ground in SE Peru, 7.5 m in SE Brazil), but often remaining in understorey and mid-levels at others, especially at edges. Compared with larger woodcreepers at site in SE Brazil, this species used slimmer trunks and branches (mean 13 cm), foraged slightly higher (mean 7.5 m, range 0-17 m), and hitched an average of 2 m up each trunk; niche overlap in these parameters moderately high with *Xiphorhynchus fuscus*, low with *Xiphocolaptes albicollis*. In Amazonia, diet and substrate overlap moderate only with much larger *Xiphorhynchus obsoletus*, which is partially tolerant of it (aggression upon contact only occasional). Most prey taken in mid-air during short but often erratic sallies after insect flushed during bird's rapid ascent (c. 55% in one study), but some items pecked or gleaned from bark surface (c. 45%); clusters of suspended dead leaves occasionally inspected.

**Breeding.** Birds in breeding condition in mid-Mar to late May in Central America (Mexico, Belize, N Guatemala), Mar-Jun in N Colombia and NE Venezuela, early Jul in NE Brazil, mid-Aug to mid-Oct in S Amazonia, and Oct to early Dec in S & SE Brazil, Paraguay and Uruguay; nest-building during late Mar to mid-Apr and incubation from latter time in Costa Rica; adults carrying food to nest in mid-May in SW Mexico; juveniles in Mar in SE Brazil and mid-Jul to late Jul in S Mexico. Few nests documented, one 12 m up in skyward-facing cavity in trunk of dead palm (*Euterpe*) was probably lined with dry leaves, another c. 7.5 m up in concealed crevice at top of slim broken-off trunk; others said to have been in tree cavities and abandoned holes of woodpeckers (Picidae) but with no additional data. Clutch apparently 3 white eggs, average 20 × 15 mm in Argentina, 21.5 × 16 mm in Tobago; incubation sessions at one nest 2-58 minutes, separated by recesses of 7-25 minutes; bird often returned to nest with dead leaf; observations at one nest suggested that it was attended by a single adult, but at another two adults seen together while feeding young.

**Movements.** Apparently resident throughout range. In S Mexico, three of four individuals translocated to nearby site soon returned to their territories. Present at ant swarms in forest and shade coffee plantations in SW Panama in comparable numbers during Jan-Apr but decreased markedly in coffee during May-Jun, suggesting that it wanders from forest more during non-breeding season.

**Status and Conservation.** Not globally threatened. Fairly common to common from C Mexico locally through Costa Rica and Panama, and over much of Amazonia and rest of South American range, but inconspicuous and often difficult to detect visually. Uncommon and possibly local in Guyana and at some sites in SC Amazonia, and apparently absent from much of E Amazonia; locally fairly common in Tobago, despite its absence from Trinidad. Densities in mid-successional vegetation and mature floodplain-forest in SE Peru suggested to be 9-19 birds/100 ha; home range estimated at 3-5 ha at Costa Rican site, but 9 ha at site in SE Peru. Generally believed to be moderately sensitive to habitat disturbance and requires at least patchy forest, but some populations may show greater degree of sensitivity than others. In various studies in SE Brazil, was found to survive in fragments as small as 50 ha, below which most populations disappear; remained abundant in 40-ha fragment connected to continuous forest, but declined significantly in smaller fragments not so well linked to forest, and especially in isolated ones. One study further documented a significant "edge-effect", with birds recorded less frequently within 200 m of forest edge. Sharp decline noted on Yucatán Peninsula following major hurricane, but recovered to pre-hurricane abundance within two years (in areas where forest had not been subsequently burnt).

## Genus *GLYPHORYNCHUS* Wied, 1831

### 10. Wedge-billed Woodcreeper

#### *Glyphorynchus spirurus*

**French:** Grimpar bec-en-coin

**Spanish:** Trepatroneos Picoeña

**German:** Keilschnabel-Baumsteiger

**Taxonomy.** *Neops spirurus* Vieillot, 1819. South America = "Cayenne".

An exceptionally small and morphologically distinctive woodcreeper that, despite appearing similar to a *Xenops* (Furnariidae), is allied with woodcreepers on the basis of both anatomy and pterylosis. Possibility that more than one species is involved suggested by existence of two markedly different song types, combined with several well-differentiated races; however, molecular data suggest gene flow between some neighbouring, morphologically distinctive subspecies. Significant genetic distances have been documented between some populations, but geographical pattern difficult to explain: genetic differentiation inconsistent with subspecific taxonomy, but may better support geographical patterns defined by vocalizations. All birds in C Brazil E from R Tapajós tentatively placed with *paraensis*, but those from E bank of R Xingu said to be intermediate between that and *inornatus*; recent records from NE Bolivia (Santa Cruz) also probably attributable to latter race; more work needed to clarify limits of races. Characters of *rufigularis* possibly lie within range of individual variation of *castelnaudii*, a highly variable taxon. Described race *sublestus* (S Central America) synonymized with individually variable *pectoralis* (birds from Nicaragua and Costa Rica intermediate between the two), which intergrades with *pallidulus* in E Panama (Caribbean slope in SE Colón). Thirteen subspecies recognized.

#### **Subspecies and Distribution.**

*G. s. pectoralis* P. L. Selater & Salvin, 1860 - Central America, from S Mexico (S Veracruz, N Oaxaca, Chiapas, mostly Caribbean slope), C Guatemala (Caribbean slope, rarely Petén) and Belize, S to Costa Rica (both slopes) and C & W Panama (on Caribbean Slope E to E Colón, on Pacific slope to W Chiriquí).  
*G. s. pallidulus* Wetmore, 1970 - E Panama (Caribbean slope from SE Colón E through San Blas, Pacific slope from E Panamá E to N Darién) and adjacent NW Colombia (N Chocó).  
*G. s. subrufescens* Todd, 1948 - Pacific coast of SE Panama (R Jaqué Valley, in SW Darién), W Colombia (N Chocó and Antioquia S to Nariño, also upper valleys of R Atrato and R San Juan) and W Ecuador.  
*G. s. integratus* J. T. Zimmer, 1946 - N Colombia (upper R Sinú E to middle Magdalena Valley and S to W Boyacá, also E of Andes from Norte de Santander S to NW Arauca) and W Venezuela (Zulia, S Táchira, W Mérida, NW Barinas, SE Lara).  
*G. s. rufigularis* J. T. Zimmer, 1934 - NW Amazonia, N of Amazon, from C Colombia (S from Meta and Vichada) and S Venezuela (S Bolívar, Amazonas) S to NE Ecuador (upper R Napo) and NW Brazil (E to E bank on upper and NW bank on lower R Negro).  
*G. s. amacurensis* Phelps, Sr. & Phelps, Jr., 1952 - NE Venezuela (Sucre, Delta Amacuro).  
*G. s. spirurus* (Vieillot, 1819) - NE Amazonia, N of Amazon, in E Venezuela (NE Bolívar), the Guianas and N Brazil (lower R Negro E to Amapá).  
*G. s. coronobscurus* Phelps, Sr. & Phelps, Jr., 1955 - Cerro de la Neblina (above 1400 m), in S Venezuela (S Amazonas).  
*G. s. castelnaudii* Des Murs, 1855 - W Amazonia, S of Amazon & R Napo, in E & NE Peru (S to Junin) and W Brazil (E to R Madeira).  
*G. s. albigularis* Chapman, 1923 - SW Amazonia in SE Peru (Puno) and N Bolivia (S to La Paz, Cochabamba).  
*G. s. inornatus* J. T. Zimmer, 1934 - S Amazonian Brazil (S of Amazon, from R Madeira E to R Tapajós and S to SW Mato Grosso); also recently recorded NE Bolivia (Santa Cruz).  
*G. s. paraensis* Pinto, 1974 - SE Amazonian Brazil, S of Amazon, from R Tapajós E to N Maranhão (including Marajó I).  
*G. s. cuneatus* (M. H. K. Lichtenstein, 1820) - coastal E Brazil (N Bahia S to N Espírito Santo); erroneously reported from Argentina.

**Descriptive notes.** 13-16 cm; 10.5-21 g. The smallest woodcreeper; short, upturned bill distinctly wedge-shaped, much like that of a *xenops* (*Xenops*). Nominate race has light buff lores, thin buff to buff-white supercilium behind eye, buff eyering nearly complete, sooty-brown auriculars finely streaked dull buff white; forehead greyish with pale shaft streaks; crown, nape, upper back and scapulars rich brown to russet-brown; lower back, rump and tail cinnamon-rufous to rufous-chestnut; tail with protruding spines long and conspicuous; wing-coverts russet; inner secondaries rufous, remaining secondaries and primaries dark brown, all with blackish tips; base of remiges (except outer three primaries) with wide stripe of buff to buff-white across inner webs, forming band across spread wing; malar stripe and sides of neck brown with small buff spots, streaks or triangles; throat whitish-buff to buff, lightly spotted dusky; underparts olive-brown to russet-brown, upper breast with large rounded fulvous spots, these grading to narrow streaks on lower breast, undertail-coverts washed rufous-chestnut distally; underwing-coverts and axillaries white, tending towards ochre at edge of wing; iris dark brown to amber; bill black, base of lower mandible grey; legs and feet pinkish-grey, dark grey, dark greenish or brownish-black. Easily distinguished from

other dendrocolaptids by small size and short, wedge-shaped bill; from similarly sized *Sittasomus griseicapillus* also by facial streaking and breast spots. *Deconychura stictolaema* of Amazonia and *D. longicauda* in S Central America have similar plumage patterns, but both are larger and their bills are longer, slimmer, and straight to slightly decurved. Bill shape and plumage patterns more closely approach those of *Xenops* and other small, trunk-foraging Furnariids, from which, distinguished by behavior of ascending trunks and branches using tail as a prop, rather than foraging near tips of branches with tail held outward; some

*Xenops* further differ by white cheek-stripe and others by black striping in tail. Female is like male. Juvenile is similar to adult, but breast streaking less pronounced, throat scaling darker and heavier, crown feathers with dusky edges. Races vary in throat colour (generally rufous in Amazonia, buffy to N & E), extent and shape of breast markings (spots in N South America, triangular in N & S), intensity of breast markings (heavier in N), general coloration of plumage (more russet in N, browner in S) and bill size (heavier in E); marked individual variation further complicates assessment of geographic patterns. Race *amacurensis* similar to nominate, but throat paler and yellowish, crown and underparts more olivaceous and back browner; *castelnaudii* also similar to nominate but darker and more olivaceous below, with bill shorter and stouter; *ruficularis* similar to *castelnaudii* but throat deep rufous and with less dark flecking, underparts browner (less olive), edges of remiges more rufescent, wingband darker ochraceous, size smaller and bill slimmer; *coronoboscus* most like *ruficularis* but with crown darker and more dusky-brown and underparts more olivaceous (less brownish); *albigularis* has throat and breast spots more whitish, the latter also narrower than in other races, and bill heavier. Remaining races from S Amazonia and E Brazil (*inornatus*, *paraensis*, *cuneatus*) similar to each other, with throat paler and buffier than in *castelnaudii*, and markings on breast less extensive and more triangular; *inornatus* has dark flecking on throat browner and spotting largely restricted to upper breast, leaving browner (less olive) belly largely unmarked; *cuneatus* browner above than *castelnaudii*, with paler throat more heavily and extensively marked, bill much heavier; *paraensis* closely similar to *cuneatus*, but with overall plumage more olive-brown (less ferruginous), throat spotting slightly rufescent, bill even heavier. In N of range, race *pectoralis* similar to *castelnaudii* but with throat cinnamon-buff, breast markings triangular, longer and extending to upper belly; *pallidulus* like *pectoralis* but paler; *subrufescens* similar to *pectoralis* but darker, smaller, with breast streaking reduced; *integratus* like *subrufescens*, but paler both above and below, and with throat a paler buff in color. VOICE. Sings relatively infrequently, primarily at dusk and dawn, occasionally during day. Song geographically variable, with at least 3 song types, from Central America and NW South America, N and W Amazonia, and SE Amazonia and Atlantic forests of E Brazil; birds in both Central America and most of Amazonia give an ascending series of upslurred whistles. In Central America and NW Colombia song a rapidly ascending, accelerating and somewhat slurred series of c. 25 bubbly notes in less than 3 seconds, "twee-lee-lee-le-lee-ee-ee-ee-ee-ee"; in N & W Amazonia a series of relatively clear whistles that ascends more slowly, 4-12 notes in 2-3 seconds, "too-e too-e tu-tu-tu-tue" "tue" "tue" "tweetweet"; in Manaus notes are more burry and almost run together. Song in SE portion of range 2 short, clear whistles in with second note somewhat lower in frequency than first, "treeee, treep". Characteristic call heard far more often, a sneezing "cheeyf!", "chiff!", "schip" or "ksh", often repeated once or twice; also strident "psieh" or "djcep", often doubled; nestlings give sharp rapid peeping, and fledglings a descending series of 5-6 scratchy notes, the first loudest, "kekekekiki".

**Habitat.** Primarily tropical evergreen forest in lowlands and foothills, less frequently lower montane evergreen forest. Amazonian populations occur principally in *terra firme* and floodplain forest, occasionally in gallery forest, palm swamps, riverine scrub, or seasonally flooded forest (both *várzea* and *igapó*); ranges from S Amazonia a short distance into *cerrado* region. Mostly in interior of mature forest, less often forest edge and older second growth; sometimes visits bamboo thickets, younger second growth, tree plantations, or even scattered trees amid clearings. At one site captured slightly more frequently within unbroken forest than at treefall gaps. Generally below 1200 m; locally into lower subtropical zone to 1500 m in SW Costa Rica & SW Panama, 1800 m in Venezuela, and 2100 m in SW Panama and Colombia.

**Food and Feeding.** Diet chiefly arthropods, but occasionally takes vegetable matter. Diversity of prey significantly lower than that of larger woodcreepers, showing a positive correlation with taxa captured in traps placed on tree trunks. Stomachs from SE Peru contained mostly beetles (found in 74% of stomachs in sample); those from S Mexico mostly ants (especially *Pheidole*), with smaller numbers of beetles, termites (Isoptera) and pseudoscorpions. Spiders, hemipteran and homopteran bugs, planthoppers (Homoptera), flies, small larvae, and small seeds and other vegetable matter recorded in small quantities. Most prey taken are minute (usually less than 5 mm) and difficult to identify in the field. Usually forages in pairs, less frequently alone, and often with mixed-species flocks that pass through its territory; facultatively joins foraging flocks, especially in understorey (in various studies, 40-48% of observations were of birds in flocks, and present in up to 45% of flocks studied at Amazonian sites); shows marked preference for flocks led by *Thamnomanes* antshrikes. Hitches rapidly up trunks and sometimes limbs, either directly or spirally, primarily in lower and middle strata (in one study, 96% of observations less than 7 m above ground), less

## Family DENDROCOLAPTIDAE (WOODCREEPERS) SPECIES ACCOUNTS

frequently into subcanopy or canopy; seems to prefer thick trunks with either flaky or rough bark, rather than slimmer trunks and branches. Most prey pecked or gleaned from surface of or crevices in trunks, or at edges of lichen clumps; regularly also flakes bark, hammers on wood, and pries off larger strips of bark. Unlike most woodcreepers, almost never follows army ants, instead seen near them almost exclusively when mixed-species flocks casually pass by active swarms; seemingly attracted more to bird activity than to ants and the prey they flush. When over ants, forages 1-15 m up, usually on relatively thick (10-50 cm) vertical trunks at periphery of swarm. Usually seen at ant swarms as singles and pairs, sometimes family groups. Subordinate to all larger woodcreepers, and observed being either supplanted or displaced by *Dendrocincla merula* and *D. fuliginosa*, *Xiphorhynchus susurrans* and *Dendrocolaptes sanctithomae*. Often quite nervous, regularly flicking wings, especially when agitated.

**Breeding.** Breeds mostly Mar-Jun in Costa Rica, May-Oct in Panama, but during both dry seasons Jan-Apr and Jun-Nov in the Guianas; nests with eggs in early Oct in Belize, mid-Apr to late Jun in SE Nicaragua and Costa Rica, late Feb in NW Colombia, late Jan to mid-Apr in N Amazonia, and late Sept to early Dec and mid-Feb to Jun in E Amazonian Brazil; nest building late Jan (French Guiana); nestlings in mid-Apr in Costa Rica, in late May in C Amazonian Brazil and in mid-Nov in French Guiana; and recently fledged young in early Feb in Surinam and mid-Jul in Panama; birds in breeding condition also in early Nov in Belize, Jul in Nicaragua and Costa Rica, early Feb to mid-Jun in E Amazonian Brazil, and late Sept to early Oct in S Amazonia, and Jan-Apr in N & SE Colombia, S Venezuela, NW Brazil and Guianas. Nest a shallow woven cup of fine rootlets, root hairs, dried stems or other fibrous material, c. 60 mm wide and 65 mm deep, placed in natural cavity within hollow tree, decaying stump, amid vine tangle, between buttress roots or furrowed trunks, at base of dead palm frond, or sometimes old hole of woodpecker (Picidae) used; cavity generally less than 6 m above ground, usually much lower, entrance usually a narrow slit, with nest cup sometimes well below entrance and near, or even below, ground level. Clutch 2 white eggs, rarely 1 or 3, average  $19 \times 15$  mm, laid on alternate days; sexes share in incubation, brooding, and brood-feeding; parents continue to bring material to nest during incubation, eggs attended constantly, incubation shifts at one nest 18-90 minutes; newly hatched chick has pink skin, long grey down; at one nest, chicks brooded for 76% of morning when 1-2 days old, and when 1 week old fed with single tiny insects 20 times in 5 hours; nestling period 17 days. High rate of nest failure in one study attributed to mortality caused by flooding after heavy rains.

**Movements.** Largely resident throughout range; may show limited altitudinal migration in Costa Rica. **Status and Conservation.** Not globally threatened. Fairly common to common over most of range; uncommon in N at some sites in Mexico, Belize and Honduras. Geographically isolated race *cuneatus* uncommon in what little forest remains within its limited range in E Brazil; its populations should be monitored. Estimated densities in *terra firme* forest in French Guiana remarkably high, 28-36 pairs/100 ha, but those in mature floodplain-forest in SE Peru believed to be significantly lower, at 9 pairs/100 ha of occupied territory; density likewise low at a Panamanian site, only 5 pairs/100 ha. Home ranges of individually marked birds in French Guiana averaged c. 3 ha; whereas one study documented what appeared to be exclusive home ranges, in most studies home ranges found to overlap broadly with no areas of exclusive use. Large, overlapping home ranges may account for unusual combination, reported in many mist-net studies, of high rates of capture but low rates of recapture. Despite a preference for interior of mature forest, an ability to survive in second growth and forest fragments at many sites suggests a lower degree of sensitivity to habitat disturbance than is true of most woodcreepers; even so, various studies have recorded significantly lower abundances up to 8-12 years after sites selectively logged, but at one site captures in second growth 25-35 years old were close to those in mature forest. Although found in one study to survive in reduced numbers even in relatively small fragments over long term, birds in these fragments grew rectrices more slowly than did those in continuous forest, suggesting that they were in poorer physiological condition.

PLATE 32

Family DENDROCOLAPTIDAE (WOODCREEPERS)  
SPECIES ACCOUNTS

Genus *DRYMORNIS* Eyton, 1852

11. Scimitar-billed Woodcreeper

*Drymornis bridgesii*

French: Grimpar porte-sabre

Spanish: Trepatroncos Chinchero

German: Degensehnabel-Baumsteiger

Other common names: Bridges's Woodcreeper, Scimitar-billed/Bridges's Woodhewer

**Taxonomy.** *Nasica bridgesii* Eyton, 1849, interior of Bolivia; error = Mendoza, Argentina. May be ancestral to all other Dendrocolaptidae; syrinx structure differs from that of all others, and genus is one of very few not infested by *Platyacarus* leather mites. Characters ascribed to proposed race *meridionalis* (from La Pampa, in Argentina) appear to reflect largely individual variation. Monotypic.

**Distribution.** SC South America in SE Bolivia, W Paraguay, W & C Uruguay, extreme S Brazil (SW Rio Grande do Sul), and Argentina (S to E Neuquén and N Rio Negro, E to Corrientes and Entre Ríos, rarely NE & SW Buenos Aires).

**Descriptive notes.** 29-35 cm; male 76-90 g, female 87-110 g. Large woodcreeper with heavy body, relatively short tail, long sickle-like bill. Bold white supercilium and moustachial stripe contrast conspicuously with dark rufous face mask and submoustachial stripe; forehead and crown rufous-chestnut to dark brown, nape slightly lighter; back and wing-coverts cinnamon-brown to light reddish-brown, remiges darker brown, rump and tail rufous-chestnut; throat white, underparts warm reddish-brown boldly streaked with white throughout, each streak edged with dark brown, streaks broad on breast and sides, narrower on belly and even more so on undertail-coverts; iris yellowish or light greyish-brown to dark brown; bill brown to black, paler (sometimes pinkish) lower mandible darkening distally; legs and feet horn-coloured, grey or dull black. Sexes similar. Juvenile has side of neck streaked with dark and light chestnut, thighs clear cinnamon, bill short and straight; fledgling has greyish to yellowish-grey bill with yellow gape-flanges. **Voice.** Song a loud, rapid sequence of whistled notes, often descending and ending in jumble, described as "deWEEdel-DLEEdeL-DLEEdeL..." or long "tweedle, tweedle, tweed, twee, twee..." that first accelerates, then loses volume. Only woodcreeper noted for duetting, and distinctively tilts head back when singing. Calls include loud "tsissik", also sharp "cheedle" contact call.

**Habitat.** Primarily Chaco woodland and scrub (especially stands of *Trithrinax*), *espinillo* (*Prosopis-Acacia*) savanna, palm savanna (mostly of *Butia yatay*) in E Argentina, also dry subtropical woodland; sometimes frequent edges, gardens and other human-altered habitats, and, in more arid regions, open scrub. Often on ground. Mostly lowlands, to 600 m, but recorded to over 1000 m.

**Food and Feeding.** Diet chiefly arthropods, but some vegetable matter also taken. Apparently eats mostly spiders, but also centipedes (Chilopoda), millipedes (Diplodopa), scorpions, and insects, including locusts (Acrididae).

caterpillars, and larvae of beetles and ant-lions (Myrmelionidae). Spends much time in foraging on ground, where often in small groups with mixed-species flocks of furnariids. Unlike other woodcreepers, quite adept at running on flat surfaces, but also climbs trees, both hitching up vertical trunks and perching crosswise on horizontal branches. Appears to obtain prey chiefly by probing into bromeliads, the ground, and holes amid trees and cacti; most prey seems to be taken from ground. When flushed, often moves with undulating flight to nearby trees, where apparently prefers inclined rather than vertical limbs.

**Breeding.** Nest-building in late Sept/early Oct, eggs in early Oct to Dec, nestlings late Sep to mid-Nov; adult feeding fledged young in mid-Oct in Argentina; birds with enlarged gonads in Oct-Dec in Paraguay and NE Argentina (Corrientes), and female with ovary small in early Jun in C Argentina (La Pampa); moulting in Feb in Paraguay. Nest in cavity, often in tree (including *Erythrina*, *Celtis*, *Prosopis*, *Acacia*, *Melia*, *Schinus*) or in palm, either natural cavity or old hole of woodpecker (Picidae), but occasionally in old nest of Rufous Hornero (*Furnarius rufus*) and even in unused chimney, entrance generally 1.5-2 m above ground, but cavity often 20-50 cm in depth, with internal width 9-15 cm, and opening 6.5-8 cm in diameter; laying on bed of leaves, bark or wood chips, often of eucalyptus (*Eucalyptus*) or *Aspidosperma*. Clutch 3 white eggs, rarely 2, average 31 × 24 mm, laid on consecutive days; incubation period 14 days; nestling period 21 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon to fairly common; possibly more abundant in S of range. Rare in E Bolivia, where found only recently; uncommon in Alto Chaco of NW Paraguay, and in Uruguay; uncommon in W Rio Grande do Sul, in Brazil, where first found in 1970. Apparently more common in C Argentina, but rarely reported at edge of range in Buenos Aires region, probably due to lack of suitable habitat. May be only moderately sensitive to human disturbance.

**Bibliography.** Azpiroz (2001), Belton (1973, 1984), Capurro & Bucher (1988), Castellanos (1932), Cory & Hellmayr (1925), Cuello & Gerzenstein (1962), Darrieu & Camperi (1990), Doering (1875), Dunning (1993), Istein (1948), Fraga (2002), Friedmann (1927), Holmberg (1939), Kratter *et al.* (1993), Kudon (1982c), Meyer de Schauensee (1966), Mezquida (2001b), Narosky & Yzurieta (1993), Narosky *et al.* (1983), Navas (1970), Navas & Bô (1986), Olrog (1959a), de la Peña (1977, 1987, 1988, 1997), de la Peña & Rumboll (1998), Pereyra (1937), Pinto (1978), Plotnick & Pergolani de Costa (1955), Ridgely & Tudor (1994), Rodriguez (1985), Short (1975, 1976), Sick (1993), Stotz *et al.* (1996), Vigil (1977), Wetmore (1926), White & Selater (1883).

## Genus *NASICA* Lesson, 1830

### 12. Long-billed Woodcreeper

#### *Nasica longirostris*

**French:** Grimpur nasican

**German:** Elfenbeinschnabel-Baumsteiger

**Spanish:** Trepatroncos Piquilargo

**Taxonomy.** *Dendrocopus longirostris* Vieillot, 1818, Boca do Igarapé Piaba, near Obidos, Pará, Brazil.

May be ancestral to all Dendrocolaptidae with exception of *Drymornis*. Birds from localities S of R Amazon having paler upperparts and more tawny underparts sometimes separated as race *australis*, but differences appear to be attributable to individual variation; by contrast, birds from S bank have significantly longer bill than those from N bank, suggesting that recognition of two races may be warranted; further study needed. Monotypic.

**Distribution.** Amazonia & R Orinoco from E Colombia and S Venezuela S to C Ecuador, NC & E Peru, Amazonian Brazil (E to C Roraima, Amapá and Maranhão, S to N Mato Grosso and S Tocantins) and N Bolivia; apparently absent from Guianan shield with exception of C & E French Guiana.

**Descriptive notes.** 35-36 cm; 78-92 g. Large, highly distinctive woodcreeper with small head and long neck, large but slim body, long tail, and exceptionally long bill only slightly decurved. Blackish-brown crown, nape and auricular region, crown and nape with sharply defined whitish-buff streaking, bold white supercilium complementing clean white throat and foreneck; back, rump, wings and tail bright cinnamon-rufous to rufous-chestnut, tips of outer primaries dark brown; breast and sides boldly marked with broad black-framed white streaks, remaining underparts olive-buff with combination of spotting and barring (pattern

possibly age-dependent); iris yellowish-brown, reddish-brown or dark-brown; bill ivory to light grey or yellowish-grey, with lower mandible often dusky at base; legs and feet grey to brown. Sexes similar. Juvenile is paler below, often with belly faintly barred, also streaks on breast paler and less distinctly fringed. **VOICE.** Song, given at infrequent intervals through day, a series of generally 3-5 long whistles, each lasting c. 1 second and beginning sharp, but trailing off gradually at end, compo-

nent notes variously described as "whoowOOOooo", "twooooooóoo" or "weeeeééééé"; when agitated, series may accelerate, lengthen, and notes become twittery and accented at end, e.g. "ooooo-ip". Calls include loud and relatively harsh, stuttering "chat-ak" or "chat-at-at" and chuckling notes; aggressive in response to imitations of song, often approaching closely while giving harsh calls.

**Habitat.** Primarily flooded forest, swamp-forest and river-edge forest, but regularly frequents adjacent *terra firme* forest and occasionally gallery forest within drier *cerrado* region. Occurs both inside forest and at edges, less frequently around clearings, in second growth, or even in gardens. Rarely far from water, often at lake margins, and resident in small numbers in mature forest on older river islands. Lowlands below 300 m; to 500 m at some sites.

**Food and Feeding.** Diet poorly known; probably mostly arthropods but also known to take small reptiles and amphibians. Stomach contents have included large scorpions and cockroaches (Blattodea), and grasshoppers (Acrididae); also observed to eat a large katydid (Tettigoniidae) 3-4 cm in length. Usually encountered singly, less frequently in twos; often alone, but sometimes with mixed-species flocks. Forages primarily on trunks and large limbs from mid-levels to canopy; sometimes descends to open understorey of seasonally flooded forest when exposed by low water levels. Has been speculated that use of mainly horizontal branches allows this species to have a bill that is very long but also relatively straight. Appears to obtain prey mainly by gleaning and probing in clusters of dense vegetation, especially epiphytes and bromeliads, also in bark crevices, knot-holes and palm fronds; may be specialized on bromeliads. Forages primarily by hitching along canopy limbs and probing into bases of leaves, but sometimes descends to forage in understorey at ant swarms, where prey taken from ground both by pecking and by short sallies; once observed to rummage through leaves on ground. Can be highly aggressive towards other dendrocolaptids, supplanting all but the somewhat larger *Hylexetastes*.

**Breeding.** Nestlings in Feb in E Ecuador; juveniles in Jan and May in upper Orinoco region and in Feb in S Amazonia. One nest was located in cavity 4 m up in small tree in small clearing; nestlings fed by both parents.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon to fairly common throughout its extensive range; apparently rare on river islands and at fringes of range in French Guiana and N Bolivia. Vocalizations relatively conspicuous, and species is often comparatively easy to observe for a woodcreeper. Densities in mid-successional forest at site in SE Peru estimated at 1.5-3 pairs/100 ha, but in nearby late-successional stages only 0.25 pairs/100 ha. Suggested as being highly sensitive to habitat modification and disturbance.

**Bibliography.** Bates & Parker (1998), Bates *et al.* (1989), Borges *et al.* (2001), Brace *et al.* (1997), Camargo (1957), Cherrie (1916a), Cory & Hellmayr (1925), Foster *et al.* (1994), Graves & Zusi (1990), Griscom & Greenway (1937, 1941), Gyldestolpe (1945a, 1945b), Hafler (1988), Hellmayr (1907a, 1907c, 1910), Hilty (2003a), Hilty & Brown (1986), Karr, Robinson *et al.* (1990), Meyer de Schauensee (1950a, 1964, 1966), Parker *et al.* (1982), Penard & Penard (1908-1910), Peres & Whittaker (1991), Phelps & Phelps (1963), Pinto (1938, 1947, 1978), Remsen & Parker (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robbins *et al.* (1991), Robinson (1997), Robinson & Terborgh (1997), Rodner *et al.* (2000), Rosenberg (1990), Schubert *et al.* (1965), Servat (1996), Sick (1993), Sillett *et al.* (1997), Sneath (1913, 1914), Stotz *et al.* (1996), Taczanowski (1884), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1994), Tostain *et al.* (1992), Willis (1977, 1983d, 1992c).

## Genus *DENDREXETASTES* Eyton, 1851

### 13. Cinnamon-throated Woodcreeper

#### *Dendrexetastes rufigula*

**French:** Grimpur à collier **German:** Perlhals-Baumsteiger **Spanish:** Trepatroncos Gorgicanelo  
**Other common names:** Streak-throated Woodcreeper/Woodhewer

**Taxonomy.** *Dendrocolaptes (orthocolaptes) rufigula* Lesson, 1844, "Cayenne".

Close relationship to *Campylorhamphus* proposed in one study. Race *devillei* considered possibly a separate species by some authors, but vocalizations like those of other races. Four subspecies recognized.

**Subspecies and Distribution.**

*D. r. devillei* (Lafresnaye, 1850) - W Amazonia from C Colombia, E Ecuador and E Peru E to W Brazil (E to R Madeira, probably also to R Negro) and S to N Bolivia.

*D. r. rufigula* (Lesson, 1844) - NE Amazonia, N bank of Amazon, in E Venezuela (NE Bolivar, S Delta Amacuro), the Guianas and N Brazil (N Roraima, and R Negro E to Amapá).

*D. r. monilliger* J. T. Zimmer, 1934 - Amazonian Brazil S of Amazon (from R Madeira E to lower R Tocantins, S to Mato Grosso).

*D. r. paraensis* Lorenz, 1895 - Amazonian Brazil S of Amazon (E of R Tocantins in E Pará).

**Descriptive notes.** 22.5-27 cm; male 64-74 g, female 66-77 g. Relatively large, heavy-bodied woodcreeper with relatively short wings, short stout bill with slightly hooked tip. Nominant race is largely medium-brown above, paler and more cinnamon on crown, rufous-chestnut wings, rump and tail; narrow whitish streaks at junction of nape and back; paler below, more cinnamon-brown, throat brightest, approaching rusty buff, broad, conspicuous, black-bordered whitish streaks across breast, sometimes weak barring on lower belly and, especially, undertail-coverts; iris red to light brown; bill horn-grey, bluish-horn, or brownish to dull greenish-yellow; legs and feet slate-grey, greenish-grey, bluish-black or brown. Distinguished from similarly sized *Dendrocolaptes certhia* by greenish to horn-coloured bill, little or no barring, streaking across breast and, in nominate, neck. Female like male, possibly smaller on average. Juvenile undescribed. Race *paraensis* most similar to nominate, but with obvious white supercilium, larger bill, more rounded streaking on breast; *devillei* has weaker pattern, usually with

unmarked belly and only faint, buffy shaft streaks on breast and sides, not continuing around hindneck; *moniliger* is duller and less rufescent overall than previous, but with streaks on breast and neck slightly bolder and with more obvious dark borders. **Voice.** Song, mostly at dawn and dusk, often in near darkness, a rapid grating trill that initially accelerates but then slows near end, sometimes sputtering at first, but almost invariably ending in a characteristic “tchew” or “eernh”. Despite geographic variation in plumage patterns, song varies little throughout Amazonia but possibly more so at N edge of range, where it does not slow as obviously at end.

**Habitat.** Humid Amazonian forest, both *terra firme* and flooded; forested sand ridges and savanna forest in the Guianas. Largely at edges, in mid- to late-successional growth, and in taller second growth, often near water; less frequently in canopy of primary forest; especially partial to palm trees. One of few woodcreepers occurring on Amazon river islands, where it occupies both older forests and those dominated by *Cecropia*. Primarily lowlands below 500 m; occasionally to 950 m on E slopes of Andes, and recorded once at 1200 m in Ecuador.

**Food and Feeding.** Diet poorly known; probably largely arthropods, but often observed pecking at clusters of fruit. Stomach contents have included beetles and locusts (Acrididae). Usually forages from mid-levels to canopy, often alone, but also with mixed-species, canopy flocks; usually encountered singly, less frequently in twos. Forages not only on large trunks and limbs in mid-levels of trees, but also in foliage of outer limbs of canopy, and especially in palm fronds. Appears to obtain prey mostly by gleaning and by probing into and rummaging among clusters of dense vegetation, including both live and dead leaves, epiphytes and palm fronds; nearly 25% of observations in one study involved foraging in dead palm leaflets or clusters of dead leaves amid live palms.

**Breeding.** Breeds mainly during the short dry season in the Guianas; flying young being fed in Oct in French Guiana. Nests in hollow tree, abandoned woodpecker (Picidae) hole or thatched roof; pair seen to bring dead leaves to a cavity 20 m up at base of fronds of the palm *Jessenia bataua* in Aug–Sept in French Guiana, but subsequent inspection revealed no further activity; average territory size 14 ha in late-successional forest in SE Peru. Clutch 2–3 white eggs, 28.5 × 22 mm.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to common, but often local, throughout its range. Both difficult to observe and rarely captured in mist-nets, thus best censused by using its distinctive song. Densities in mid-successional growth along a river in SE Peru estimated at 5–6.5 pairs/100 ha, but in nearby late-successional forest only 3 pairs/100 ha. Suggested as being highly sensitive to habitat modification, even disappearing from selectively logged forest at one site.

## Genus *HYLEXETASTES* P. L. Sclater, 1889

### 14. Red-billed Woodcreeper

#### *Hylexetastes perrotii*

**French:** Grimpard de Perrot **German:** Weißbart-Baumsteiger **Spanish:** Trepatroncos Piquirrojo  
**Other common names:** Brigida's Woodcreeper (*brigidai*); Uniform Woodcreeper (*uniformis*)

**Taxonomy.** *Dendrocolaptes Perrotii* Lafresnaye, 1844. Colombia; error = “Cayenne”.

Close to and possibly conspecific with *H. stresemanni*, having similarities in voice and morphology; race *insignis* of latter has characters suggesting possible intergradation between the two. Race *uniformis* treated by some authors as a separate species on basis of differences in plumage and, to lesser extent, body size, despite vocal similarity and a lack of behavioral data; *brigidai* recently described as a full species on basis of diagnostic but relatively subtle plumage characters, but is similar structurally and vocally to *uniformis*; intermediates not known, but total number of specimens small. Morphological and vocal similarities to nominate (songs possibly not identical), however, suggest that both are better considered races of present species. Three subspecies recognized.

#### **Subspecies and Distribution.**

*H. p. perrotii* (Lafresnaye, 1844) – NE Amazonia, N of Amazon, in E Venezuela (R Yuruán, in NE Bolívar), the Guianas and N Brazil (lower R Negro and C Roraima E to Amapá).

*H. p. uniformis* Hellmayr, 1909 – S Amazonia, S of Amazon, in Brazil (R Madeira and tributaries E to upper R Xingu, S to SW Mato Grosso) and NE Bolivia.

*H. p. brigidai* da Silva *et al.*, 1995 – SE Amazonian Brazil, S of Amazon, in Pará from R Xingu E to R Tocantins and R Araguaia.

**Descriptive notes.** 25–30 cm; male 112–137.5 g, female 110–145 g (*perrotii*), male 86.5–121 g, female 95–118 g (*uniformis* and *brigidai* combined). Large, heavy-bodied woodcreeper with large head, short but massive bill, heavy legs and feet; relatively short tail often excessively worn, possibly a result of foraging close to ground. Nominative race has whitish lores, frosty white moustachial stripe from lores back across head just below auriculars, olive-brown throat with whitish to buffy centre; otherwise largely uniform, smoky brown to olive-brown above (including wing-coverts), with remiges, rump and tail bright rufous to rufous-chestnut, primary tips dusky; breast greyish-brown, belly buffy brown, undertail-coverts tending to be more rufescent; about half of individuals have indistinct dusky grey bars on belly

and undertail-coverts; iris brown to reddish-brown, even red; bill wine-red to brownish; legs and feet shades of green or olive, often with brown or grey intermixed. Distinguished from *H. stresemanni* by more weakly barred underparts, pale moustachial stripe; from somewhat similar *Dendrocolaptes certhia* mainly by bold facial markings and noticeably stouter body. Sexes similar. Juvenile is similar to adult, but crown weakly streaked, on average more heavily barred and possibly more rufescent below, eyes dark grey, shorter bill dusky to blackish, sometimes with pale lower mandible. Races *uniformis* and *brigidai* are on average smaller in all dimensions than nominate, but limited overlap: *uniformis* is uniformly brown almost throughout, lacks paler throat and whitish facial markings, belly sometimes finely and indistinctly barred; *brigidai* is somewhat more boldly patterned than *uniformis* (tending towards nominate), has more conspicuous and darker barring on belly and underwing-coverts, contrasting pale grey lores, paler and more yellowish chin and throat. **Voice.** Song, given almost exclusively at first or last light from canopy of tall tree near centre of territory, but occasionally during day in territorial interactions, a loud, ringing series of 2–6 whistles each c. 1 second long and almost disyllabic, first part longer and sometimes lower in pitch, second higher and more emphasized, notes described as “wreccccéé” or “erweeék” and song as “kyuu-hee, kyuu-hee...” or “hooooooreet, hoooooreet, hoooreet, hoooreet”, series often repeated only few times; heard at close range, song less noticeably disyllabic and not descending like song of *Xiphocolaptes promeropirhynchus*; both members of pair apparently sing, but at slightly different pitch. Songs of *uniformis* and *brigidai* similar to that of nominate, but possibly not identical. Various calls described as snarling “screee-wip”, “nyeah” and “nyip, nyeeek, nyeeek, weewewewiep”, the last in response to tape playback of song; also growling series of “cag” notes, faint grunting “whinh, whaiih, whaiih” directed at nearby *Xiphocolaptes*, and faint disyllabic whistles by dependent young. Quality of calls, and even songs, similar to that of *Xiphocolaptes*.

**Habitat.** Primarily humid *terra firme* forest in Amazonian lowlands and hilly Guianan interior; sometimes occurs in gallery or seasonally flooded forests or those growing on sandy soils; also encountered rarely in savanna forest in Surinam, and in semi-deciduous woodland on upper R Xingu (Brazil). Mainly in interior of tall primary forest, but sometimes at edges and even in selectively cut forest; avoids younger second growth, but uses older second growth on occasion. Largely restricted to lowlands, but ascends to 600 m in Serra dos Carajás (Pará, in Brazil).

**Food and Feeding.** Diet mostly small arthropods; larger items, including small vertebrates, sometimes taken. Prey often quite small (including ant and wasp larvae), but this may reflect availability rather than preference; small prey sometimes left for other species. Stomach contents have included spiders, beetles, and Hymenoptera (both ants and wasps). Centipedes (Chilopoda), spiders, scorpions and katyids (Tettigoniidae) often taken over army ants, cockroaches (Blattodea) only rarely so; both frogs and snakes recorded as being eaten, and winged ants taken during hatches. Forages singly and in pairs. Regularly associates both with army-ant swarms and with mixed-species flocks. When foraging over ants, uses near-vertical trunks of medium to large size (5–50 cm), generally perching either below 2 m (often less than 1 m) or at 10–15 m above ground; most prey taken in clumsy sallies to ground, but significant percentage gleaned from trunks, limbs or foliage. Away from ant swarms, often forages among mixed-species flocks in middle to upper levels of forest, on trunks of large trees, where gleaning or pecking probably more important than sallying; occasionally seen to follow flocks of Red-throated Caracaras (*Daptrius americanus*), presumably for prey they flush. Sometimes digs in rotten wood, termite nests and, occasionally, in epiphytes or debris, for which massive bill seems well adapted. Generally looks outwards when hitching or perched, rather than peering inwards at trunks as do *Xiphorhynchus*. Despite clumsy movements and often sluggish behaviour, is dominant over all other dendrocolaptids and all thamnophilid antbirds, probably because of its large size; forages low in best positions over sides and front edge of ant swarms, and regularly chases and supplants conspecific and other woodcreepers over swarms, excluding *Dendrocolaptes picumnus* at one site, and supplanting species as large as *Xiphocolaptes promeropirhynchus*; only one observation of displacement by another species, a forest-falcon (*Micrastur*).

**Breeding.** Little known; eggs and most aspects of breeding biology undescribed. Birds with gonads greatly enlarged in early Oct and moderately enlarged in late Mar in Surinam, and with moderately enlarged gonads in late Jun in S Pará (Brazil); probably breeds in dry season, e.g. Jun–Sept near Manaus (Brazil), where single dependent fledglings seen beginning Aug to Oct; carrying bark chips to cavities in both late Feb and mid-Aug, and apparently brooding at former nest in mid-Mar, in French Guiana; begging juvenile in early Feb and immatures from mid-Jan to late Jun in S Amazonia. Nests observed during construction were in cavities near tops of large stumps. Fledglings may remain with parents until May of following year (Manaus); fledged young of year dominant over one parent (apparently male) but dominated by other (apparently female). Has been speculated that only 1 egg laid, and that breeding success low.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Status poorly known; probably uncommon to rare throughout its range, and apparently present at most sites in low densities and on large, mutually exclusive territories. In Brazil, rare to uncommon at well-worked sites near Alta Floresta (Mato Grosso), at Tapajós National Park (Pará), in reserves N of Manaus, in N Roraima, and at sites in Amapá, but surprisingly common at Caxiuanã National Forest (Pará); rare to uncommon in the Guianas, and known in Venezuela from only two records. Densities at site near Manaus estimated at 3–5 birds/100 ha. Appears to be highly sensitive to habitat modification, as evidenced by observations of its abandoning ant swarms that move into second growth, and its disappearance from both selectively logged sites and small forest fragments after isolation; reappearance at an isolated fragment indicates, however, that it will cross areas of unsuitable habitat to locate active ant swarms. An indicator species for tropical lowland evergreen forest in both N & S Amazonia.

**Bibliography.** Anon. (2003b, 2003c), Bangs (1930), Bates & Parker (1998), Bates *et al.* (1989), Bierregaard (1988), Bierregaard & Lovejoy (1989), Blake (1963), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1925), Dubs (1992), Fry (1970), Gyldestolpe (1951), Haffer (1992), Haverschmidt (1957), Haverschmidt & Mees (1994), Hellmayr (1909a, 1910), Hilty (2003a), Jullien & Thiollay (1998), Karr, Robinson *et al.* (1990), LeCroy & Sloss (2000), Meyer de Schauensee (1966), Meyer de Schauensee & Phelps (1963), Novaes & Lima (1990), Oniki & Willis (1972, 1982), Penard & Penard (1908–1910), Phelps & Phelps (1963), Pinto (1938, 1978), Ridgely & Tudor (1994), Schubart *et al.* (1965), Sick (1993), da Silva & Oniki (1988), da Silva, Lima & Marceliano (1990), da Silva, Novaes & Oren (1995), Snethlage (1914, 1926), Snyder (1966), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Thiollay (1990, 1992, 1994), Thiollay & Jullien (1998), Tostain (2002b), Tostain *et al.* (1992), Willis (1977, 1982c), Willis & Oniki (1978, 1988c), Zimmer, Parker *et al.* (1997).

### 15. Bar-bellied Woodcreeper

#### *Hylexetastes stresemanni*

**French:** Grimpard de Stresemann **Spanish:** Trepatroncos de Stresemann  
**German:** Wellenbauch-Baumsteiger

**Taxonomy.** *Hylexetastes stresemanni* Snethlage, 1925, Acajutuba, lower Rio Negro, Brazil.

Close to and possibly conspecific with *H. perrotii*, having similarities in voice and morphology; characters of race *insignis* suggest possible intergradation between the two species. Has apparently hybridized intergenerically with *Dendrocolaptes picumnus* in W Brazil, one of few cases of hybridization in suboscines. Three subspecies recognized.

**Subspecies and Distribution.**

*H. s. insignis* J. T. Zimmer, 1934 - extreme NW corner of Amazonian Brazil on N bank of R Uaupés; sight records from adjacent Colombia (Vaupés) require verification.

*H. s. stresemanni* Sneathlage, 1925 - NW Amazonia, in Brazil from lower R Negro S to R Solimões (W limit unknown).

*H. s. undulatus* Todd, 1925 - SW Amazonia, S of Amazon, in E Peru (upper R Ucayali), N Bolivia (Pando) and NW Brazil (E to at least R Purús, probably to R Madeira).

**Descriptive notes.** 28-29 cm; male 114-125 g, female 102 g. Large, heavy-bodied woodcreeper with large head, short but massive bill, heavy legs and feet, relatively short tail. Nominate race has head, back and wing-coverts brown to olive-brown, pale shaft streaks on forehead, pale region in lores and under eye but face otherwise plain; lower back, remiges and tail rufous-chestnut, primary tips darker; throat whitish with bold dark streaking, especially at lower edge; breast olive with black-bordered streaks of whitish to yellowish-white, blending below to buffy; lower breast unmarked but belly and undertail coverts with narrow but well-defined blackish bars; iris

red to red-brown or bright brown; bill laterally compressed, blunt-tipped, dark reddish to reddish-brown; legs and feet greyish-green to dusky. Distinguished from *H. perrotii* by more heavily barred underparts, plainer face; from similar *Dendrocolaptes picumnus* by larger size, heavier body, plain face and upperparts, more massive, reddish bill. Sexes similar. Juvenile has more rufous back than adult, dark spots along edges of throat and breast feathers produce apparent mix of streaking and barring, also more brownish and often noticeably shorter bill. Races differ mainly in subtle variations of colour: *insignis* is more olivaceous above than nominate, lacks forehead streaks and dark borders of breast streaks, and has more obvious moustachial stripe, weaker barring below, shorter bill; *undulatus*

is larger, also lacks streaking on forehead, and is slightly more olivaceous, less rufescent, below than nominate, with barring on belly bolder and better defined. **VOICE.** Song, given almost exclusively at first light, a loud and somewhat shrill series of 4-6 almost disyllabic "shu-reet" whistles roughly on same pitch, similar to that of *H. perrotii* but individual notes described as being shorter and more clipped; heard at close range, whistles less noticeably disyllabic, and song not descending like that of *Xiphocolaptes promeropirhynchus*.

**Habitat.** Humid forest in Amazonian lowlands, both *terra firme* and in floodplains. Generally in interior of primary forest, but probably visits edges, and possibly also older second growth on occasion. Lowlands, to c. 300 m.

**Food and Feeding.** Little known; brief observations in W Brazil suggest that diet and foraging behaviour over ants similar to those of *H. perrotii*. Tiny insects observed being eaten, but larger arthropods probably also taken when available; stomach contents comprised insects. In addition to occurrence at army-ant swarms, probably associates at least occasionally with mixed-species flocks. Forages primarily from understorey to subcanopy, probably lower when over ants than when away from them. From low perches, often on thick, vertical trunks, one bird sallied over ants to peck prey from leaves or trunks; occasionally perches crosswise on slim, horizontal stems. Quite shy and difficult to approach, even over ants.

**Breeding.** Nothing published on any aspect of breeding biology.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. A rarely seen and little-known species; probably uncommon to rare, but occurs in one of the regions of Amazonia that is best-preserved and least known ornithologically. Limited singing for brief periods, largely at dawn and dusk, further complicates censusing. Only 1 pair encountered in over 50 days in field at one Bolivian site, suggesting either that species has very large territories or that its habitat requirements are quite specific: congener *H. perrotii* generally found in very low densities. Said to be uncommon at upper R Urucu, in Brazil, but believed to be rare at most sites; although infrequently encountered, occurs in the large (over 2,000,000 ha) Jaú National Park. Fewer than ten records at well-worked sites in Madre de Dios, in Peru. Believed to be highly sensitive to human disturbance. Possibly merits reassessment of conservation status as Near-threatened, or even Vulnerable.

**Bibliography.** Borges *et al.* (2001), Cory & Hellmayr (1925), Dunajewski (1939), Gonzaga (1989), Gyldenstolpe (1951), Haffer (1992), Hilty & Brown (1986), LeCroy & Sloss (2000), Lloyd & Marin (2000), Meyer de Schauensee (1966), Parker & Remsen (1987), Parker *et al.* (1982), Peres & Whittaker (1991), Pinto (1938, 1978), Ridgely & Tudor (1994), Sick (1993), Sneathlage (1925), Stotz *et al.* (1996), Willis (1982c), Zimmer (1934c).

# Genus *XIPHOCOLAPTES* Lesson, 1840

## 16. Strong-billed Woodcreeper

### *Xiphocolaptes promeropirhynchus*

**French:** Grimpar géant **German:** Starkschnabel-Baumsteiger **Spanish:** Trepatroncos Picofuerte  
**Other common names:** Giant Woodcreeper; Great-billed/Orinoco/Rusty-breasted Woodcreeper ("orenocensis group")

**Taxonomy.** *Dendrocolaptes promeropirhynchus* Lesson, 1840, no locality = "Bogotá", Colombia. Sometimes considered to form a superspecies with *X. albicollis*. Races usually divided into three groups, treated as separate species by some authors: "emigrans group" (Central America), "promeropirhynchus group" (mountains of W & N South America), and "orenocensis group" (primarily Amazonian lowlands). Populations in mountains of N South America may be closer to those in Amazonian lowlands than to those in Peruvian and Bolivian Andes; affinities of race *crassirostris* problematic, possibly allied with "orenocensis group" but occurring W of Andes. Assessment of geographical variation complicated by marked individual variation within taxa in almost all geographically variable characters. Race *ignotus* sometimes merged with nominate; *rostratus* possibly a junior synonym of *fortis*; *virgatus* poorly defined, and intergrades with nominate on E slope of C Colombian Andes; and *sanctaemartae* very similar to *procerus*; racial identity of birds in Guianan lowlands uncertain, tentatively placed with *tenebrosus*. Thorough taxonomic revision needed. If by nothing else, Central American, Andean and Amazonian populations united by vocalizations that are remarkably similar, given degree of morphological differentiation. Published records from N Argentina apparently referable to misidentified *Dendrocolaptes picumnus*. Twenty-five subspecies recognized.

#### Subspecies and Distribution.

*X. p. omitemensis* Nelson, 1903 - subtropical zone in SW Mexico (Sierra Madre del Sur, in C Guerrero).  
*X. p. sclateri* Ridgway, 1890 - E & SE Mexico (SE San Luis Potosí, Hidalgo, W Veracruz, N Oaxaca).  
*X. p. emigrans* P. L. Sclater & Salvin, 1859 - mountains (rarely lowlands) from S Mexico (Chiapas), N Guatemala, W Belize and El Salvador E to NC Nicaragua.  
*X. p. costaricensis* Ridgway, 1889 - highlands of C Costa Rica and SW Panama (Chiriquí).  
*X. p. panamensis* Griscom, 1927 - mountains on Pacific slope of S Panama (Veraguas, possibly also Coclé).  
*X. p. sanctaemartae* Hellmayr, 1925 - N Colombia (Santa Marta Mts).  
*X. p. rostratus* Todd, 1917 - N Colombian lowlands in Córdoba and Bolívar (Sinú Valley E to Serranía San Lucas and Magdalena Valley).  
*X. p. fortis* Heine, 1860 - range unknown, likely either N Colombia or Venezuela (known only from unique type, no locality given).  
*X. p. virgatus* Ridgway, 1890 - upper tropical to temperate zones of W slope of C Colombian Andes, also on E slope (E to R Magdalena).  
*X. p. promeropirhynchus* (Lesson, 1840) - subtropical and temperate zones in N Colombia (W slope of E Andes E of R Magdalena) and W Venezuela (Perijá Mts, Trujillo, Mérida, Táchira).  
*X. p. procerus* Cabanis & Heine, 1859 - tropical and subtropical zones in mountains of N & C Venezuela (W Zulía, N Mérida and NW Lara E to Sucre, S to N Monagas and E Guárico).  
*X. p. macarenae* Blake, 1959 - Macarena Mts and E foothills of C Colombian Andes (S Meta, Caquetá).  
*X. p. neblinae* Phelps, Sr. & Phelps, Jr., 1955 - subtropical zone on Cerro de la Neblina, in S Venezuela (S Amazonas); possibly also adjacent N Brazil.  
*X. p. tenebrosus* J. T. Zimmer & Phelps, Sr., 1948 - upper tropical zone on tepuis of SE Venezuela (Chimantá-tepui and Mt Roraima, in SE Bolívar) and adjacent Guyana (Acary Mts), probably also adjacent tepuis of N Brazil; also lowlands of the Guianas (except Surinam).  
*X. p. ignotus* Ridgway, 1890 - subtropical and temperate zones of Ecuadorian Andes.  
*X. p. crassirostris* Taczanowski & Berlepsch, 1885 - subtropical zone in Andean foothills in SW Ecuador (W El Oro, Loja) and NW Peru (Tumbes, Piura).  
*X. p. compressirostris* Taczanowski, 1882 - temperate zone of N Peruvian Andes (Amazonas, Cajamarca, San Martín).  
*X. p. phaeopygus* Berlepsch & Stolzmann, 1896 - temperate zone of C Peruvian Andes (Junín).  
*X. p. lineatocephalus* (G. R. Gray, 1847) - subtropical and temperate zones of Andes from SE Peru (Cuzco) S to NW & C Bolivia (La Paz, Cochabamba, Santa Cruz).  
*X. p. solivagus* Bond, 1950 - upper tropical zone on E slope of E Peruvian Cordillera (Chanchamayo region, in Junín, probably also N to Huánuco).  
*X. p. orenocensis* Berlepsch & Hartert, 1902 - NW Amazonian lowlands, N of Amazon, from C Colombia and S Venezuela S to NE Ecuador, NE Peru and NW Brazil (E to R Negro).  
*X. p. berlepschi* Sneath, 1908 - Amazonian lowlands of W Brazil S of R Solimões (E to R Madeira); W limit of range unclear.  
*X. p. paraensis* Pinto, 1945 - C Amazonian Brazil, S of Amazon, from R Madeira E to R Xingu, S to N Mato Grosso (Alta Floresta).  
*X. p. carajensis* da Silva et al., 2002 - SE Amazonian Brazil, S of Amazon, from R Xingu E to R Tocantins and R Araguaia, in Pará.  
*X. p. obsoletus* Todd, 1917 - lowlands of N & E Bolivia (La Paz E to Santa Cruz).  
**Descriptive notes.** 26-35 cm; male 111-169 g, female 102-142 g. Heaviest woodcreeper, with stocky build, medium-length tail, relatively long, decurved bill stout but laterally compressed. Nominate race has buffy lores, supercilium and moustachial stripe, contrasting dusky postocular and malar stripes; dark brown crown and nape blending to brown on back, scapulars and wing-coverts, buff streaking on crown and nape becoming narrower and less distinct on upper back; lower back russet, darkening to rufous-chestnut on rump; inner webs of remiges rufous-chestnut, outer webs tawny-brown, tips dusky; tail dark chestnut, shafts brighter; throat buffy and largely unmarked; breast and sides brownish with narrow buffy streaks that continue indistinctly onto belly, belly and undertail-coverts tawny-cinnamon with fine dark spots or bars; underwing-coverts tawny-ochraceous with black spotting; iris dark brown to amber or red; bill blackish-horn; legs and feet bluish-grey, greenish or greyish-black. Sexes similar. Juvenile has shorter bill, ochraceous tips to wing-coverts, deeper overall coloration, and pale streaks on crown, throat and breast both wider and bordered by dusky spots (producing barred appearance). Races vary mainly in size, general coloration, bill size and shape, bill colour (mostly paler than nominate and often with tip or base contrasting darker), character of streaking on breast and crown, extent of barring on belly. Within "promeropirhynchus group" (including *virgatus*, *sanctaemartae*, *procerus*, *macarenae*, *ignotus*, *fortis*, *rostratus*, *compressirostris*, *phaeopygus*, *lineatocephalus* and, possibly, *tenebrosus* and *neblinae*) races differ largely in size, bill shape and colour, overall coloration, throat pattern, width of streaking on crown and breast, and extent of streaking on back and spotting on underparts. Race *virgatus* closely similar to nominate but possibly larger and darker on average; races *sanctaemartae*, *procerus* and *macarenae* have streaking on crown finer and little or none extending onto back; *sanctaemartae* and *procerus* have throat streaked, streaking on breast narrower and more limited, belly unbanded; *macarenae* similar but throat paler and upperparts darker; *ignotus* and *fortis* again similar, but with bill heavier, overall coloration more rufescent, and throat mostly unstreaked; *rostratus* nearly inseparable from *fortis* and differing from *ignotus* only by longer bill. Birds from Peruvian Andes (*compressirostris* and *phaeopygus*) more olivaceous, with streaking on throat heavier, streaking on crown finer, back nearly unstreaked and concolorous with rump, and bill shorter; *phaeopygus* differs primarily in its near lack of crown streaking. Race *lineatocephalus* similar to *compressirostris* and *phaeopygus*, but overall coloration more rufous, rump chestnut, crown darker and distinctly streaked. Both *tenebrosus* and *neblinae* most similar to "orenocensis group", but with upperparts darker, throat more heavily streaked; *tenebrosus* differs from *neblinae* by shorter, straighter bill. Central American birds "emigrans group" smaller in size, overall coloration plainer, spotting on belly weak and streaks on head, back, and breast faint and narrow; *emigrans* is pale overall and with malar-stripe weak; *sclateri* is similar to *emigrans* but crown and malar-stripe blacker, wings duller, and streaking somewhat stronger; other Central American races (*omitemensis*, *costaricensis*, *panamensis*) differ from previous two in size, bill length and shape, overall coloration, and colour and degree of streaking on crown. Amazonian birds "orenocensis group" (including races *berlepschi*, *paraensis*, *carajensis*, *obsoletus* and *solivagus*) are larger and generally more rufescent overall (especially below), with crown blackish and boldly streaked, moustachial-stripe indistinct or lacking and, in most races, bill longer, heavier and mostly pale; races *orenocensis* and *berlepschi* weakly barred below and weakly streaked above; *berlepschi* more rufescent below than *orenocensis* and with belly more weakly spotted; *paraensis* similar to *berlepschi* but crown nearly black, and streaking on back and barring on belly both relatively bold; *carajensis* similar to *paraensis* but size smaller, underparts slightly paler, and streaking, both above and below, narrower but also denser, that on back also less extensive; races *obsoletus* and *solivagus* differ by smaller bill and in overall coloration; *solivagus* is paler and less reddish than *obsoletus*. Race *crassirostris* most similar to "orenocensis group" due to dark crown, but size smaller, striping on face bold and throat unstreaked, whitish. **VOICE.** Song, often given only a few times at dawn and dusk (from near top of large tree), a loud, ringing series of 3-10 disyllabic whistles, each lower in pitch than preceding one, described as "ooWackee, ooWackee, ooWackee, ooWackee, ooWackee, Wackity, Wackity, Wackity, Wackity, Wackity, Wack". "chu'ik chu'ik chu'ik..." or "pt-teeu, pt-teeu, pt-teeu, pt-teeu, pt-teuu", most like that of *X. albicollis*; at distance first note of each couplet often inaudible, resulting in descending series of single whistles much like song of *Hylexetastes*; song similar throughout range, but cadence in songs of Amazonian birds may average faster than in other populations. Calls include "yip, yip, yip", soft cat-like "meow", "cooo-WEEW"; also snarled "trieh-chk!" or "pahhh-JEEP" alarm, similar to comparable call of *X. albicollis*.  
**Habitat.** Variety of forested habitats from tropical lowlands to subtropical and lower temperate zones of mountains. Most races in either lowland or montane habitats, but not both; some occur in close geographical proximity but separated altitudinally. Primarily montane in Central America, N & C Andes (except lowland race *rostratus*), coastal ranges of Venezuela and tepuis, but "orenocensis group" largely restricted to Amazonian lowlands. Most montane taxa frequent humid evergreen forest and cloudforest, but others in dry forest; N races primarily in arid oak (*Quercus*), pine (*Pinus*) and pine-oak woodlands in mountains, occasionally also in both rainforest and pine ridges of lowlands. Amazonian races primarily in humid forests, primarily in *terra firme* and on floodplains, less frequently flooded forest and gallery forest. Frequents mainly interior of mature forest, regularly also more open forest, older second growth, forest edge; rarely, visits forest fragments, adjacent plantations or younger second growth. Mostly lowlands to c. 900 m in Amazonia, with montane forms generally at 1500-2800 m (rarely down to 700 m, or up to 3200 m); 1500-3500 m in Mexico, and generally above 1200 m in Guatemala and Honduras (occasionally down to 600 m in Honduras in non-breeding season, and throughout year in lowlands of Belize and Guatemala); 500-1700 m in Costa Rica and Panama; 100-3000 m (mostly above 1500 m) in Colombia; 20-2800 m (generally above 400 m) in N & W Venezuela, lowlands to 1800 m in S and in Guyana; mostly 1000-3000 m (locally to 3200 m) in Ecuador, but to c. 600 m in E lowlands; lowlands to 2850 m on E slope of Peruvian Andes.  
**Food and Feeding.** Appears to be mainly insectivorous, but small vertebrates also taken. Both a grasshopper (Acrididae) and a cricket (Gryllidae) observed being taken over ants; only report of vertebrate prey involved a small frog (*Hyla myotympanum*). Most prey appear to be quite small (mean 0.5 cm in one study), but items larger than 5 cm taken on occasion. Forages from understorey to subcanopy, less often in canopy. Usually encountered singly or in pairs, sometimes in family groups; seems generally to forage alone, sometimes with mixed-species flocks, and occasionally in association with swarms of army ants (primarily *Eciton burckellii*, also *Labidus praedator*). Only 5% of observations at site in SE Peru involved birds with understorey flocks, but seems to prefer flocks led by *Thamnomanes* antshrikes. Generally sluggish and rather inconspicuous, but sometimes quite wary, and often flying long distances between perches. Appears to forage largely by digging into dead wood or leaf litter with powerful bill; also creeps up large trunks and limbs while pecking at or probing into epiphytes, bark crevices, both live foliage and dead leaves, lichen-covered branches, or termite (Isoptera) nests. Montane birds seem especially fond of foraging among bromeliads and other epiphytes, and may specialize on them. One individual collected from arboreal ant nest. Over 95% of foraging attempts in one study represented picking, with less than 5% involving sallies. Over ant swarms usually forages low in undergrowth, mostly from vertical or slightly inclined trunks 6-25 cm in diameter, but also hops on ground or over fallen logs, digging into rotten wood or leaves. Activity over ants concentrated within 1 m of ground (but sometimes to 10 m), with pecking at items or sallying short distances to capture prey; foraging by one bird involved 3 pecks to ground, 1 to debris and 1 to trunk, and 6 sallies to ground and 1 to debris. Aggressive encounters over ant swarms have included displacing

*Dendrocolaptes picumnus* and being supplanted by *Hylexetastes perrotii*; interactions with smaller *X. guttatus* have gone both ways.

**Breeding.** Birds in breeding condition in late Mar to early May in Mexico, Belize, NW Colombia and S Venezuela, and in early Oct in Mato Grosso (Brazil); male in late Dec in SW Mexico and two in early Mar in Guatemala nearly in breeding condition, but one in Aug in Guatemala had reduced (probably regressing) gonads and others in late Jul to late Aug in S Amazonian Brazil in non-breeding condition; a bird seen carrying dead leaf, presumably to nest, in late Feb in SE Colombia; fledged young in Jan in N Bolivia, and juveniles in Feb in N Colombia and S Venezuela, and Aug in Costa Rica. Nest and eggs apparently not documented.

**Movements.** Probably resident throughout most of range; some birds in N of range may move downslope into adjacent lowlands during non-breeding season. Only a casual visitor at well-worked Monteverde Forest Reserve, in Costa Rica, suggesting some movement of local populations.

**Status and Conservation.** Not globally threatened. Uncommon but local throughout most of range. Seemingly more common in mountains of N Central America and Santa Marta region (Colombia), and at some lowland Amazonian sites; relatively rare both on Pacific slope and in Caribbean lowlands of N Central America (El Salvador, N Guatemala and Belize), throughout Costa Rica and Panama, in the tepui region of S Venezuela and N Brazil, in NW Peru, and along E Slope of Andes in Peru and Bolivia. Density in floodplain-forest in SE Peru estimated at 1 pair/100 ha, with average home range 40 ha; density in adjacent late-successional forest was 1.5 pairs/100 ha. Most populations appear to require nearly continuous forest, thus believed highly sensitive to human disturbance. One study in W Amazonian Brazil, however, noted presence not only in a small forest fragment (where encountered more frequently than in undisturbed forest), but also in forest regenerating after selective logging, and even in scrub (probably a single bird captured while moving between more continuous forest). Considered an indicator species for mid-montane humid forest in Madrean Highlands of S Mexico and mid-montane evergreen forest in N & C Andes.

## 17. White-throated Woodcreeper

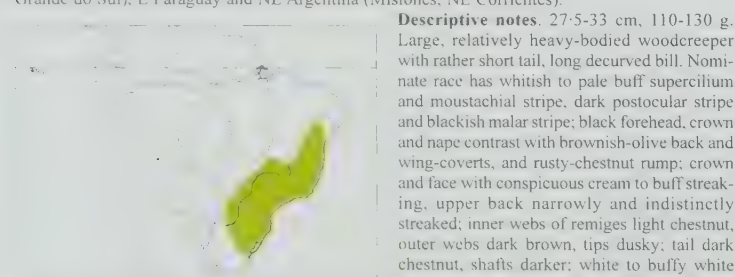

### *Xiphocolaptes albicollis*

**French:** Grimpar à gorge blanche **Spanish:** Trepatroncos Gorgiblanco  
**German:** Weißkehl-Baumsteiger  
**Other common names:** Bonfim/Vila Nova Woodcreeper (*villanovae*)

**Taxonomy.** *Dendrocopos albicollis* Vieillot, 1818, type from Rio de Janeiro, Brazil. May form a superspecies with *X. promeropirhynchus* despite some authors recognizing race *franciscanus* as a subspecies of *X. albicollis* instead of *X. falcistrois*, and others treating *villanovae* as a race of *X. falcistrois* instead of *X. albicollis*; recent phylogenetic study based on morphology allied *X. albicollis* with *X. major* instead of *X. promeropirhynchus* but failed to include *X. falcistrois*. Race *villanovae* sometimes considered a separate species. Specimens from S part of range of nominate race, having more olive (less tawny) plumage and less rufous on rump, sometimes recognized as race *argentinus*. Three subspecies recognized.

#### **Subspecies and Distribution.**

*X. a. villanovae* Lima, 1920 - known only from vicinity of type locality in NE Brazil (NE Bahia).  
*X. a. bahiae* Cory, 1919 - E Brazil (E & C Bahia).  
*X. a. albicollis* (Vieillot, 1818) - SE & S Brazil (S Bahia, S Goiás and Minas Gerais S to S Rio Grande do Sul), E Paraguay and NE Argentina (Misiones, NE Corrientes).

tawny remaining underparts, ground colour less tawny in S ("argentinus"); breast and sides boldly streaked pale buff to whitish, streaks in centre of breast bordered by darker spots, belly, thighs and undertail-coverts barred (more distinctly than on other *Xiphocolaptes*); underwing-coverts cinnamon, barred black; iris red to brown, orbital skin greenish; bill black, sometimes horn-coloured lower mandible; legs and feet yellowish-grey to dark green, brownish-grey or black. Distinguished from remarkably similar *Dendrocolaptes platyrostris* by longer, heavier bill, bold malar stripe, better-defined white throat. Sexes similar. Juveniles has shorter bill, broad drop-like spots of rusty-yellow on crown. Race *villanovae* is paler overall than nominate, with dark brown crown, more conspicuous supercilium, weaker barring on belly, shorter bill; *bahiae* is paler and browner, crown dark brown with tawny-rufous streaks, breast streaks lack dark borders, barring below restricted to a few dusky spots in centre of belly. **VOICE.** Sings primarily at dawn and dusk, sometimes adjacent to roost site; one of last birds to sing in the evening. Song typical of genus, a nasal whine followed by a loud, descending series of 4-6 disyllabic whistles, "reenht-wi-KEER wi-KEER wi-KEER wi-KEER wi-KEER wi-KEER wick" or "tee-ay, heechee heechee, hichee, hitchy...", series sometimes ending with throaty rattle, especially when agitated; both partners sing, female song hoarser but weaker. During day gives snarls, including rising "wheee", also 2-note call, possibly when alarmed, variously described as "cha-FESK", "wheee-chuck" or "eweh-wet", with initial note prolonged and forceful, and second ending in a pop.

**Habitat.** Humid Atlantic Forest, and semi-deciduous and gallery forests amid *cerrado* and Chaco. Characteristic species of Brazilian Atlantic Forest, but not completely restricted to it. In addition to primary forest, regularly frequents mature second growth, edges, occasionally even isolated trees in scrubby clearings. Occurs from lowlands to subtropical foothills above 2000 m; mostly below 1500 m, and possibly most common in tropical hill forest.

**Food and Feeding.** Mostly arthropods, but takes snails, bird eggs, and occasionally small vertebrates. Stomach contents have included cockroaches (Blattodea), beetles of various types, ants, and fly larvae; observed to take bird eggs from cavity nests. Generally encountered singly, sometimes in pairs; usually alone, but sometimes in association with either mixed-species flocks or ant swarms; dropped out of mixed-species flocks during breeding season at one site. Forages at all levels in forest, though seems to prefer lower and middle levels, and often seen quite close to the ground; not shy, but often climbs behind trunks when approached. Usually in lower strata of forest, where it moves slowly over fallen logs or up trunks, digging in and tearing off bark to expose prey hiding beneath. In one study, most foraging was concentrated on relatively large trunks (average diameter over 75 cm) at 5-8 m above ground, with maximum height only 12-13 m; often forages on rough bark, and generally on trunks and large branches. Obtains most food by gleaning, less frequently by flaking bark or pecking more forcefully. Like congeners, regularly pecks on rotting wood and forages amid bromeliads; may be a bromeliad-foraging specialist. Recorded foraging over swarms of both *Eciton burckellii* and *Labidus praedator*; one bird seen to sally from low trunk to ground after prey flushed by ants.

**Breeding.** Birds with fully active gonads in Oct-Nov in Brazil and E Paraguay, and in non-breeding condition in Apr in NE Argentina. Nest in natural cavity in tree; does not excavate nest. Clutch 2 white eggs, average 35 × 25 mm; presence of brood patch in both sexes suggests that they share in incubation and, probably, rearing of young.

**Movements.** Apparently resident throughout range; recent studies recorded its presence throughout year even at S limit of range in SE Brazil (Rio Grande do Sul).

**Status and Conservation.** Not globally threatened. Uncommon to fairly common over much of its range, and common at some sites in S Brazil; rare at fringe of range in S Paraguay (Ñeembucú region). Suggested to be only moderately sensitive to human disturbance, which may explain continued presence in relatively small fragments, older second growth and selectively logged sites. Abundance decreases with forest area, and ability to survive in smaller fragments less clear; recorded in Paraná (Brazil) in forest reserves as small as 11 ha within a matrix of fragments, even after over 40 years of isolation. Apparently less able to withstand fragmentation at sites farther N, possibly owing to greater degree of isolation of fragments; in Brazil, absent from tracts of 145 ha and 21 ha in São Paulo, and numbers significantly reduced in fragments smaller than 100 ha in Minas Gerais. May be affected detrimentally by selective cutting of its preferred large trees. An indicator species for humid broadleaf and lower montane Atlantic Forests.

**Bibliography.** Aleixo (1997), Aleixo & Galetti (1997), dos Anjos (2001a), Belton (1984), Bencke & Kindel (1999), Berlepsch & Ihering (1885), Bertoni (1901), Brooke (1983), Cory & Hellmayr (1925), Dabbene (1914), Darrieu & Camperi (1990), Davis (1945, 1946), Fraga (2002), Goerck (1999a), Höfling & Lencioni (1992), Holmberg (1939), Ihering (1898), Krügel & dos Anjos (2000), Lopes *et al.* (2003), Madroño, Robbins & Zyskowski (1997), Marini & Couto (1997), Mauricio & Dias (1998, 2001), Meyer de Schauensee (1966), Naka & Rodrigues (2000), Narosky *et al.* (1983), Olrog (1959a), de la Peña (1988), de la Peña & Rumboll (1998), Pinto (1935, 1978), Pinto & Camargo (1961), Ridgely & Tudor (1994), do Rosário (1996), Scott & Brooke (1985), Sick (1993), Sillett *et al.* (1997), da Silva & Oren (1997), Soares & dos Anjos (1999), Stotz *et al.* (1996), Willis (1979b, 1983d).

## 18. Moustached Woodcreeper

### *Xiphocolaptes falcistrois*

**French:** Grimpar à moustaches **German:** Piaubaumsteiger **Spanish:** Trepatroncos Bigotudo  
**Other common names:** Snethlage's Woodcreeper (*franciscanus*)

**Taxonomy.** *Dendrocolaptes falcistrois* Spix, 1824, no locality = Oeiras, Piauí, Brazil.

Uncertain whether affinities closer to *X. promeropirhynchus* or to *X. albicollis*. Race *franciscanus* considered a full species by many authors and a race of *X. albicollis* by some, but possibly not even a valid taxon; race *villanovae* of latter sometimes placed in present species. Two subspecies recognized.

#### **Subspecies and Distribution.**

*X. f. falcistrois* (Spix, 1824) - NE Brazil from E Maranhão and Ceará E to W Paraíba and W Pernambuco, S to NW Bahia.

*X. f. franciscanus* Snethlage, 1927 - E Brazil, W of R São Francisco, in W Bahia and N & NW Minas Gerais; specimen allegedly collected in Paraná Valley (Goiás) now believed to have been mislabelled.

Differs from *X. albicollis* in longer, slimmer bill with conspicuously pale lower-mandible, somewhat paler overall coloration (crown and facial markings brown instead of blackish), bolder face pattern, more cinnamon rump, weaker markings on crown and underparts. Sexes similar. Juvenile similar to adult, but bars and streaks on central belly broader and blackish, bill shorter, stouter and blackish with lower mandible dark greyish-brown. Race *franciscanus* is on average darker and more olive below than nominate, has narrower streaking on breast, weaker streaking on crown, also on average shorter-tailed and longer-billed, but substantial overlap between races in all characters. **VOICE.** Rarely heard song a harsh whine followed by a far-carrying series of c. 5 descending notes at intervals of c. 1 second, "nk-wiirh, week! weeer, weeer, weeur", similar to that of congeners but notes not so obviously disyllabic; has approached in response to playback of recordings of *X. albicollis*. Calls similar to that of latter species, most often a whine ending in a harsh note, "niemu-chikl".

**Habitat.** Semi-deciduous woodland, wooded *caatinga*, palm woodland (in Maranhão), and gallery forest. Typical trees at a preferred site in Minas Gerais were *Bursera leptophloeos*, *Astronium urundeuva*, *Chorisia ventricosa*, *Cavanillesia arborea*, *Spodias tuberosa*, *Hymenaea martiana*,

and *Schinopsis*. Primarily in interior of intact and lightly disturbed forest, generally frequenting tallest and most extensive forests in region, but sometimes also visits edges within suitable habitat; often at bases of calcareous hills, in mesic depressions, or in "monsoon" forest in otherwise dry habitats (especially in N of range). Known localities mostly below 550 m, but to over 800 m in N part of range.

**Food and Feeding.** Primarily insectivorous; limited observations of insect larvae, ants, beetles and snails being taken. Seen singly, in pairs, or in groups of 3-6 individuals that may represent families. Most sightings appear to be of either solitary individuals or birds in monospecific groups; sometimes seen with other dendrocolaptids, but ignored nearby mixed-species flocks on other occasions. Forages mostly along trunks and branches in mid-levels of tall forest, but sometimes descends to ground level; may be specialized on foraging among bromeliads. Observed to remove prey from tree cavities, rummage on ground among leaf litter, and remove strips of bark from trunk of a tree.

**Breeding.** Apparently breeds during austral summer: birds with enlarged gonads, one having a brood patch, in Oct-Nov in Minas Gerais; male with moderately large testes in Dec, whereas others in May-Jun (W Bahia) believed to be in post-breeding condition; specimens in May-Jun (Maranhão, Piauí) and Aug (Bahia) not in breeding condition; juvenile in mid-Jun in Maranhão. Nest, eggs and other details undescribed; presence of brood patch on a male suggests that incubation (and probably parental care) shared by both sexes.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Uncommon to rare, and very local. World population believed to be between 2500 and 10,000 individuals, and declining; considered threatened in Brazil as a whole, and endangered in state of Minas Gerais. In region occupied, vast majority of forest has already been removed and remainder is disappearing rapidly. Causes of habitat loss include burning, cutting for charcoal and conversion to agriculture, complicated by fact that forests harbouring this species are situated on richest soils in region. Even relatively large fragments can disappear quickly: one site in W Bahia that contained extensive forest occupied by this dendrocolaptid in 1988 had been completely destroyed by 1993, and another site occupied as recently as Mar 1997 was largely cleared by a road-improvement project by Nov 1998. N nominate race suggested by some as being less sensitive to human disturbance than are S populations, but this probably not the case given patchy nature of remaining fragments throughout range; recent records in N scattered among only a few localities. Legally protected in Brazil, and conservation measures have had some success in setting aside key sites as parks and reserves. Protected sites where the species survives include Serra do Baturité State Environmental Protection Area (Ceará), and Cavernas do Peruágu National Park (Minas Gerais). Future work should concentrate on reduction of forest loss throughout region (in part through better enforcement of existing laws), mapping of remaining forest fragments, creation of a system of conservation units, and promotion of sustainable use at unprotected sites. An indicator species for both gallery forest (nominate race) and tropical deciduous forest in Cerrado region (*franciscanus*) of C South America.

**Bibliography.** de Andrade *et al.* (1986, 1988), Collar *et al.* (1992), Cory & Hellmayr (1925), Gonzaga (1989), Hellmayr (1929b), Kirvan *et al.* (2001), Machado *et al.* (1998), Pinto (1938, 1952, 1978), Pinto & Camargo (1961), Reiser (1926), Ridgely & Tudor (1994), Sick (1993), da Silva & Oren (1997), Stattersfield & Capper (2000), Teixeira (1990b), Teixeira & Luigi (1989), Teixeira *et al.* (1989), Willis & Oniki (1991).

## 19. Great Rufous Woodcreeper

### *Xiphocolaptes major*

**French:** Grand Grimpar **German:** Fuchsröter Baumsteiger **Spanish:** Trepatroncos Colorado  
**Other common names:** Rufous Woodcreeper

**Taxonomy.** *Dendrocopus major* Vieillot, 1818, Paraguay.

Relationships uncertain; recent phylogenetic study based on morphology suggested an affiliation with *X. albicollis*. N nominate race and *castaneus* intergrade in N Argentina. Individual variation in plumage possibly more marked than geographical variation. Four subspecies recognized.

**Subspecies and Distribution.**

*X. m. castaneus* Ridgway, 1890 - NC & E Bolivia, SW Brazil (Mato Grosso do Sul) and NW Argentina (SE Jujuy, N Salta).

*X. m. remoratus* Pinto, 1945 - SW Mato Grosso, Brazil.

*X. m. major* (Vieillot, 1818) - Paraguay and N Argentina (Jujuy, Salta and Formosa S to Córdoba and NE Santa Fe).

*X. m. estebani* da Silva & Oren, 1991 - Tucumán, in NW Argentina.

**Descriptive notes.** 27-34 cm; male 120-150 g, female 120-162 g. Large, heavy-bodied woodcreeper with long, heavy, somewhat decurved bill. N nominate race is bright cinnamon-rufous overall, slightly more brownish or olive on crown (variable) and more chestnut on tail; remiges reddish-brown, primaries with dusky tips; lores blackish; throat pale cinnamon with whitish-buff streaking, underparts cinnamon, variable amount of buffy shaft streaks on breast and dusky brownish barring on belly; uniform cinnamon-rufous undertail-coverts; iris dark brown, rich red-brown or crimson; bill horn-coloured basally,

and horn-white distally, smoky blue-grey, or grey to greyish-olive with blackish tip; legs and feet dark greyish-olive, greenish or bluish-grey. Sexes similar. Juvenile differs from adult in generally clearer, more brilliant coloration, especially below, and more obvious breast streaking but weaker borders to crown feathers. Race *remoratus* has darker upperparts, less ferruginous underparts, whitish on throat more limited than nominate; *castaneus* is darker overall (especially on more brownish head), upperparts deeper chestnut, breast more narrowly streaked, barring on belly reduced; *estebani* is similar to nominate, but much lighter in general coloration. **Voice.** Song a slightly descending series of up to 12 disyllabic "hie!-up" whistles with loud, ringing quality, possibly longer in duration and including more notes than songs of congeners. Often gives a two-part call similar to notes of song, but more emphatic, longer, accented on second syllable, "eehr-eeek!".

**Habitat.** Dry forest, semi-deciduous woodland, Chaco woodland, gallery forest; less frequently scrub-forest, *cerrado*, wooded savanna, and even park-like habitats adjacent to forest. Largely in woodland interior, but occasionally visits savanna and edges. Primarily in tropical zone of Chaco region, but also inter-montane valleys of adjacent Andes; to 1800 m, mostly below 1500 m.

**Food and Feeding.** Largely insectivorous, but small vertebrates taken at least occasionally. Stomach contents chiefly invertebrates, comprising ants, grasshoppers (Acrididae), various types of beetle, pentatomid bugs, earwigs (Dermaptera), Lepidoptera larvae, and remains of other insects, but with trace amounts of vegetable matter and bits of snail shell. Has been observed eating a hylid frog 7 cm long, and taking (but not definitely eating) an unidentified colubrid snake 40 cm in length; a remarkable observation of an individual first pecking on and then eating a bat. Usually encountered alone or in pairs; occasionally in groups of three, probably representing families. Creeps like a woodpecker (Picidae) along trunks and large branches from understorey to subcanopy; also regularly descends to forage on ground, especially among open groves of trees. Most prey probably obtained by gleaning and probing, but sometimes rummages among leaf litter on ground or pecks loudly on trunks.

**Breeding.** Nest with incubated eggs in mid-Nov in Argentina (Santa Fé); laying female in early Nov in Paraguay; birds in breeding condition in Oct (but not in Sept) in N & E Bolivia and Paraguayan Chaco. Nest in natural cavity or old woodpecker hole 1-6-4 m above ground, usually lined with dry leaves, straw or wood shavings; cavity depth 1-1-6 m, entrance hole 8 × 13 cm, may enlarge narrow cavity entrance by using bill. Clutch 2-3 pure white eggs, average 36 × 26 mm.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare to uncommon over most of range; apparently more common at some sites, e.g. the *campos-cerrados* of C Paraguay. Relatively rare at edge of range in N Pantanal (Brazil). Although fairly common and widespread in the past at well-wooded sites in NW Argentina (Salta, Tucumán), most recent observers have found it to be scarce in this region. Key to this species' presence seems to be the availability of intact forest. Considered to be only moderately sensitive to habitat loss and other forms of human disturbance, and thus a relatively low conservation and research priority. An indicator species for gallery forest in C South America.

**Bibliography.** Brace *et al.* (1997), Camperi (1988), Cherrie (1916b), Chubb (1910), Cintra & Yamashita (1990), Cory & Hellmayr (1925), Dabbene (1912), Dubs (1992), Esteban (1948), Friedmann (1927), Grant (1911), Hartert & Venturi (1909), Hayes & Argaña (1990), Holmberg (1939), Ihering (1900), Kerr (1892), Kratter *et al.* (1993), Laubmann (1940), Lönnberg (1903), Mazar Barnett (2002), Meyer de Schauensee (1966), Narosky & Yzurieta (1993), Narosky *et al.* (1983), Olrog (1959, 1963b, 1979b), de la Peña (1977, 1987, 1988, 1997), de la Peña & Rumboll (1998), Pinto (1978), Ridgely & Tudor (1994), Sick (1993), da Silva & Oren (1991), Storer (1989), Stotz *et al.* (1996), Wetmore (1926), White & Selater (1883), Zotta (1936).

## 20. Northern Barred Woodcreeper

### *Dendrocolaptes sanctithomae*

**French:** Grimpur vermiculé **Spanish:** Trepatroncos Barrado Norteño  
**German:** Nördlicher Bindenbaumsteiger

**Taxonomy.** *Dendrocops Sancti-Thomae* Lafresnaye, 1852, "in Sancti-Thomae Insula"; error = Santo Tomás, Izabal, Guatemala.

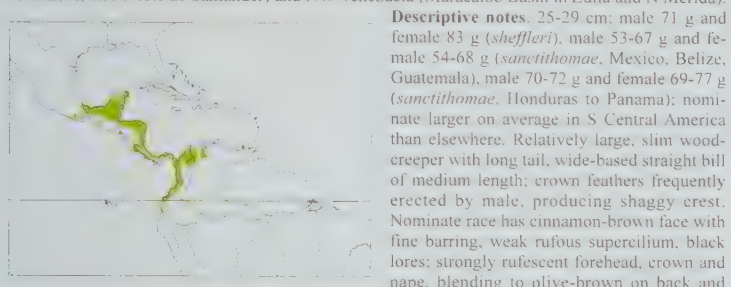

Until recently considered conspecific with *D. certhia*; accorded full species status on basis of vocal, behavioural and morphological differences. Vocal characters suggest that race *punctipictus* may also be a separate species, but more study needed; proposed race *hyleorus* doubtfully distinct from *punctipictus*, may reflect intergradation between it and nominate in N Colombia (Magdalena, Santander). Variation in both bill length and extent of pale base of lower mandible is clinal in nominate; this, combined with a typographical error, resulted in description of races *nigrirostris* (Costa Rica, Panama) and *colombianus* (W Colombia, NW Ecuador), both subsequently synonymized. Supposed variation leading to description of *legtersi* (Yucatán Peninsula) appears to reflect an artifact of type series. Four subspecies recognized.

#### Subspecies and Distribution.

*D. s. sheffleri* Binford, 1965 - Pacific slope of Sierra Madre del Sur in SW Mexico (Guerrero, Oaxaca).  
*D. s. sanctithomae* (Lafresnaye, 1852) - Central America and NW South America from S Mexico (C Veracruz, Yucatán Peninsula) S on Caribbean slope to Panama; locally also Pacific slope in S Mexico (one record in Chiapas), Honduras, El Salvador and from NW Costa Rica S to Panama, N & W Colombia (Chocó region) and NW (one record WC) Ecuador.

*D. s. hesperius* Bangs, 1907 - Pacific-slope lowlands of SW Costa Rica (including Osa Peninsula) and adjacent W Panama.

*D. s. punctipictus* Phelps, Sr. & Gilliard, 1940 - N Colombia (middle Magdalena Valley S to Santander, also Norte de Santander) and NW Venezuela (Maracaibo Basin in Zulía and N Mérida).

**Descriptive notes.** 25-29 cm; male 71 g and female 83 g (*sheffleri*), male 53-67 g and female 54-68 g (*sanctithomae*, Mexico, Belize, Guatemala), male 70-72 g and female 69-77 g (*sanctithomae*, Honduras to Panama); nominate larger on average in S Central America than elsewhere. Relatively large, slim woodcreeper with long tail, wide-based straight bill of medium length; crown feathers frequently erected by male, producing shaggy crest. Nominant race has cinnamon-brown face with fine barring, weak rufous supercilium, black lores; strongly rufescent forehead, crown and nape, blending to olive-brown on back and

wing-coverts, crown feathers obviously barred with black, back somewhat less so; cinnamon-rufous to rufous-chestnut remiges, rump and tail, primary tips dusky; chin, throat and underparts golden to cinnamon-buff (becoming slightly duller in colour to S), narrowly but crisply barred black throughout; iris light to dark brown, sometimes with reddish component; bill largely blackish, cutting edges pale, base of lower mandible pale flesh, greyish or brownish (decreasing in extent from N to S); legs and feet dark brown or black to dull greyish-green, bluish or horn-coloured. Distinguished from similar *D. certhia* mainly by combination of conspicuous black lores, rufous cap, largely blackish bill and better-defined and more extensive barring below (extending up through chin). Female is slightly larger than male. Juvenile is similar to adult, but barring below more diffuse, especially on belly, undertail-coverts more rufescent, also more uniformly black bill. Race *sheffleri* differs most obviously in creamy-buff bill, also narrower barring below, sparser barring above, greyish-tinged lower breast contrasting with more yellowish upper breast and throat; *hesperius* resembles nominate, but barring below conspicuously finer, that on upperparts weaker, and ground colour both below and on crown duller; *punctipictus* has conspicuous triangular spots on breast, imparting weakly streaked or spotted appearance. **Voice.** Song, given largely at dawn and dusk (intermittently also throughout day), and often from concealed perch in canopy, a series of 2-12 (usually 3-5) loud whistles each c. 0.5 second long and rising sharply at end, described as "oowit, oowit, oowit, OOWIT, OOWIT!", or as "téw-wee, téw-wee, téw-wee" or repeated "dwoi'ik"; song of *punctipictus* markedly different, beginning as series of long whistles on one pitch, but ending in harsh chatter. Various calls described as "oiyñk" or "awwýñk", snarling "wi-kaii" and "caa", grunting "eh", murmured "auh-auh-auh-auh", quiet "wh-whee", also nasal "kiyarr" sometimes in series; when agitated, may give a series of "gobbling" notes that rise and fall in pitch.

**Habitat.** Humid forest. Primarily tall evergreen forest, but occurs less frequently in low-stature rainforest on Yucatán Peninsula, gallery forest in NW Costa Rica and mangroves along coast of Colombia; also tropical semi-deciduous forest. Occasionally extends into cloudforest and even pine-oak (*Pinus-Quercus*) woodland, at least during non-breeding season. Generally in interior of mature forest, but regularly visits forest edge, older second growth and even tree plantations near forest; captured in nets slightly less frequently in natural forest gaps than within mature forest. Lowlands and foothills to c. 1800 m; most frequent in tropical zone below 1000 m.

**Food and Feeding.** Diet mainly arthropods, but small vertebrates also taken. Preys largely on grasshoppers (Acrididae), cockroaches (Blattodea), beetles and scorpions, also on spiders, centipedes (Chilopoda), caterpillars, and smaller numbers of many other invertebrates. Small lizards not only taken by adults (20% of all prey in one study), but also delivered to nests. Stomach contents comprised mainly orthopterans in one study, mainly beetles in another, with smaller numbers of cockroaches, cicadas (Cicadidae), hemipteran bugs, spiders and centipedes. Despite possible bias caused by difficulty of observing small items in field, most prey identified in one study were relatively large, chiefly 20-50 mm, but with one lizard 130 mm in length. Associates at least on occasion with mixed-species flocks, but most often encountered at swarms of army ants (*Eciton burchelli*, less frequently *Labidus praedator*); roughly 70% of foraging time was spent in association with ant swarms at one Panamanian site. Apparently a nearly "professional" ant-follower that

not only uses vocalizations of other ant-followers to locate swarms, but also checks regularly on inactive bivouacs; rarely visits more than one ant colony per day. Usually present at swarms singly or in pairs, but three or, rarely, four birds have been seen together. Forages mainly in understory and mid-levels of forest, less frequently into subcanopy or even canopy. Often forages in undergrowth when associated with swarming ants, where two main areas of activity evident, one at 0.4-0.6 m over ants moving across ground, another 2-6 m up in association with columns of ants ascending trunks; a less obvious area of activity 15 m up may correspond to foraging away from ants, or to birds not foraging at the time. Most foraging over ants occurs from perches on near-vertical trunks 5-100 cm in diameter, from which makes short-distance sallies of less than 1 m (occasionally to 3 m, rarely farther) to capture prey against foliage, trunks, vines, the ground or, occasionally, in the air; most prey taken either from ground or 3-6 m up. Regularly gleans and pecks items from trunks, crevices and epiphytes. Somewhat less aggressive than smaller woodcreepers, but regularly supplants both them and conspecifics, less frequently antbirds (Thamnophilidae); *Dendrocincla fuliginosa* and Ocellated Antbird (*Phaenostictus mcleannani*) are common targets of aggression. Females dominant over slightly smaller males. When away from army ants, regularly encountered both alone and with mixed-species flocks, less frequently with monkeys, e.g. troops of squirrel monkeys (*Saimiri oerstedii*) in S Costa Rica; seems to forage less often with mixed-species flocks than does Amazonian *D. certhia*. Away from ants, most foraging occurs 2-15 m above ground on vines and larger trunks. Often rather lethargic and easily overlooked. Has been observed "anting".

**Breeding.** Season May-Jul in Costa Rica, where nests with eggs found until late Jul; female with egg in oviduct in late Jul in El Salvador; birds in breeding condition in Apr-May and early Aug in S Mexico and Belize, and early Jul-Aug in Guatemala and Nicaragua; in breeding condition in late Nov-Mar and adult feeding fledgling in mid-Jun in Colombia. Nest at 1.5-6 m, usually low down, in hollow trunk of palm, broken-off branch or other natural cavity, lined with leaves and flakes of bark. Clutch 2 white eggs, average 30.5 × 24 mm; joint parental care indicated by presence of brood patch on male, and disappearance each morning of male of one pair soon after courting (suggesting that male was incubating). Has been recorded molting while still in breeding condition.

**Movements.** Probably resident; records at upper end of elevational range may reflect dispersal from lowland breeding sites.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common within humid forest to 1000 m over most of range; possibly more common than elsewhere in lowlands on Caribbean slope and S Pacific slope of Costa Rica. Less common at upper elevations, and uncommon to rare at margin of range on Pacific slope in S Mexico (Oaxaca) and where habitat either limited, as in El Salvador, or marginal, as on Yucatán Peninsula. Race *punctipictus*, which may deserve full species status, is probably among the most threatened of all dendrocolaptid populations as a result of extensive habitat destruction within its highly restricted, lowland range in N Colombia and NW Venezuela. All populations have undoubtedly declined following extensive loss of lowland forest throughout region. It has been speculated that marked fluctuation in numbers, even within suitable habitat, may contribute to local disappearance from marginal sites such as Barro Colorado I, in Panama, where always scarce. Like most ant-following species, requires a relatively large home range and considered to be sensitive to forest fragmentation and other forms of human disturbance, and unlikely to colonize new areas across barriers of unsuitable habitat. An indicator of tropical lowland evergreen forest on Gulf-Caribbean slope, in the Chocó lowlands and in N South America. **Bibliography.** Anon. ## 21. Amazonian Barred Woodcreeper

### *Dendrocolaptes certhia*

**French:** Grimpur barré **Spanish:** Trepatroncos Barrado Amazonico

**German:** Amazonien-Bindenbaumsteiger

**Other common names:** Concolor(ed) Woodcreeper (*concolor*)

**Taxonomy.** *Picus certhia* Boddaert, 1783, "Cayenne".

Until recently considered conspecific with *D. sanctithomae*; separated on basis of vocal, behavioural and morphological differences. Race *concolor* sometimes treated as a separate species, but vocal and morphological data suggest that it is instead a pale, weakly barred representative of present species; characters of birds from R Tapajós E to R Tocantins (NC Brazil), described as race *ridgwayi*, apparently represent introgression between *concolor* and *medius*. Birds from E Peru showing characters of *polyzonus* may instead reflect hybridization between *radiolatus* and *juvuanus*. One study indicated genetic differences between *radiolatus* and *concolor* as great as or greater than those between it and *D. sanctithomae*. Six subspecies recognized.

#### Subspecies and Distribution.

*D. c. radiolatus* P. L. Sclater & Salvin, 1868 - W Amazonia, N of Amazon, in SE Colombia, NW Brazil (W of R Negro), E Ecuador and N & C Peru (largely W of R Ucayali, S to Junín).

*D. c. certhia* (Boddaert, 1783) - N & NE Amazonia, from extreme E Colombia (E Guainía), S & E Venezuela and the Guianas, S to Amazon in N Brazil (from R Negro E to Amapá).

*D. c. juvuanus* H. von Ihering, 1905 - SW Amazonia, S of Amazon, in E Peru, W Brazil (E to R Madeira, S to NW Mato Grosso) and N Bolivia.

*D. c. concolor* Pelzelin, 1868 - S Amazonian Brazil, S of Amazon, from R Madeira E to R Tocantins, S to Mato Grosso and N Tocantins; also extreme NE Bolivia.

*D. c. medius* Todd, 1920 - SE Amazonia, S of Amazon, from R Tocantins E to NW Maranhão; isolated population in NE Brazil (Pernambuco, Alagoas) may no longer exist.

*D. c. polyzonus* Todd, 1913 - SW edge of Amazonia in C Bolivia, possibly extending into adjacent SE Peru.

and tail cinnamon-rufous to rufous-chestnut, primary tips dusky; pale grey to dirty white chin and throat contrast conspicuously with deep buff to fulvous from breast through undertail-coverts, fine dusky barring almost throughout underparts; underwing cinnamon-rufous to ochre-yellow; iris reddish to dark brown; bill dark red to brownish, usually paler on cutting edges and at base of lower mandible; legs and feet brown, greenish, grey, olive or black. Distinguished from similar *D. sanctithomae* mainly by lack of rufous tones on crown, brownish to red bill, pale lores and throat, more diffuse barring below; lacks streaking on crown and breast characteristic of *D. picumnus* and most other large woodcreepers; race *concolor* distinguished from race *uniformis* of *Hylexetastes perrotii* by smaller size, longer tail, generally slimmer body, and vocalizations (both have red bill). Female is slightly larger than male. Juvenile is similar to adult, but barring less pronounced both above and below, lighter regions of plumage somewhat paler, lacks pale streaks on crown, bill often shorter and darker. Race *juruanus* is closely similar to nominate, but lacks golden streaks on crown; *polyzonus* is much more richly coloured than previous, more cinnamon-brown above, and ochraceous-brown below; *radiolatus* has coloration similar to last, but much more strongly and broadly barred with black on back, greater coverts and underparts; *concolor* is barred inconspicuously or not at all, has redder bill, dark throat and plumage coloration that is variable geographically, greyer in SW, more ochraceous to N, with fine barring weak or absent W of R Tapajós, but often visible (especially below) in population E of there ("ridgwayi"); *medius* most similar to nominate but crown duller, face pale grey and scaly in appearance, underparts paler and more weakly marked. Voice. Song, given mostly at dawn from concealed perch in or near forest canopy, sometimes at dusk, rarely during day, is a rapidly delivered series c. 2 seconds long of roughly 8-15 simple notes, ascends slightly at first and then descends and slows, "whee-whee-EE-EE-Ee-ee-ee-ee-eu eu eu" or "tew-tew-tew-tew-tew-tew-tew-tew-tu tu tu tu", resembling a laugh or whinny; notes delivered more slowly than in song of *D. picumnus*; a "forced song" was described as abrupt "cai-i-i-i-i-i-i-i". Calls include snarls, a "chah-eef" alarm, squeaky "chi-ku", hissing "piiuh"; various calls by young birds, e.g. "fi-u", "fi-fi-fi-fi-u", "fiu".

**Habitat.** Humid evergreen forest. Largely tall *terra firme* forest, but also both flooded forest and floodplain-forest; less frequently *campinarana*, savanna forest, mangrove swamps; also deciduous and gallery forests along S fringe of Amazonia. Most common in interior of mature forest with relatively open understorey, but regular also in older second growth and at forest edge. Isolated population in NE Brazil occurred in both tall forest and more scrubby second growth. Amazonian lowlands and adjacent foothills; most frequent below 900 m, but to c. 1400 m in tepui region.

**Food and Feeding.** Primarily insectivorous, but small vertebrates also taken. Over ants, preys mostly on grasshoppers (Acrididae) and cockroaches (Blattodea), also on beetles, scorpions, spiders, centipedes (Chilopoda), caterpillars, and, to lesser degree, many other invertebrates (including moths and even crabs). Small lizards appear to be most common vertebrate prey, but frogs also taken. Stomach contents included mainly beetles, also hemipteran bugs, flies, caterpillars, various orthopterans, ants, spiders, and millipedes (Diplopoda). Prey items often relatively large, regularly 20-50 mm, and one centipede was 130 mm in length; these regularly battered against tree trunks before being swallowed. Although considered a "professional" ant-follower by some workers, others have suggested that it forages alone or with mixed-species flocks more often than with ants; compared with *D. sanctithomae*, forages over ants less but with flocks more, but, like that species, sometimes seen in association with troops of monkeys. Usually attends ants (primarily *Eciton burchelli*, possibly also *E. rapax* and *Labidus praedator*) singly or in pairs, but three or, rarely, four birds recorded together. Forages mostly in understorey when associated with ants, but frequently up into mid-levels or subcanopy when away from them. Activity concentrated 2-6 m above ground, in association with columns of ants ascending trunks; less obvious activity centres within 0-5 m of ground and 15 m up, apparently corresponding to, respectively, foraging over ants moving across ground and foraging away from ants. Possibly excluded from low positions by large antbirds (Thamnophilidae) and by larger *D. picumnus* and *Hylexetastes*. Hunts mostly from perches on near-vertical to slightly leaning trunks 5-50 cm in diameter, from which makes short sallies of less than 2 m (rarely 3 m or more) to capture prey, taken mostly 2-5 m up over ants, with foraging closer to ground less frequent than in *D. sanctithomae*; most sallies directed at foliage (over 55% of all sallies in one study), occasionally at trunks, vines, the ground, or even in air. Gleans and pecks items from trunks, stumps, vines and foliage less frequently than does *D. sanctithomae*, and forages among dead leaves only on occasion. Regularly supplants conspecifics and most smaller woodcreepers, especially *Dendrocincla fuliginosa*, sometimes also antbirds; in turn, is supplanted regularly by larger *D. picumnus*, *Nasica longirostris* and *Hylexetastes*, and occasionally by several smaller *Xiphorhynchus*. Larger females apparently dominant over smaller mates. Away from ants, single birds or pairs often associate with mixed-species flocks, but also encountered regularly alone; most foraging occurs 2-15 m above ground on vines and larger trunks, from which prey often taken by sallies of 1-2 m to undersides of leaves, less frequently gleaned from trunks. Açaí palms, which harbour many arthropods, a favoured substrate in *várzea* forest in lower Amazonia.

**Breeding.** Birds in breeding condition in both Feb-Apr and mid-Aug to late Oct in N part of range (S Venezuela, Guianas, N Brazil), in early Dec to late Jun on Marajó I (Brazil), and in early Oct in S Amazonia; in non-breeding condition in May in E Colombia and Jun in N Brazil (Amapá); incubating bird in early Dec at Belém (Brazil), adult carrying food in mid-Oct in French Guiana, and small young in nest in early Sept at Manaus (Brazil); fledglings in late Apr and early Oct to early Jan in S Venezuela and the Guianas, mid-Nov to early Jan at Manaus, and mid-Jun to late Aug and early Nov to mid-Feb in S Amazonian Brazil; suggested that breeding may be on a cycle of 9-10 months in some places, although likely concentrated during dry season at most sites. Remains paired throughout year. Nests in old woodpecker (Picidae) hole or natural cavity in tree, once 2 m up in a trunk 25 cm in diameter, once in a cavity 2-5 m in depth; estimated territory size 15 ha in SE Peru. Clutch 1 white egg, one 30 × 24 mm; parental care apparently by both sexes. Birds molting in late Oct (Mato Grosso, Brazil) and in late Feb to early Mar (Cerro de la Neblina, Venezuela); molt appears to follow breeding, but seasonality from site to site remains unclear.

**Movements.** Resident.

**Descriptive notes.** 26-28.5 cm; male 62.5-73.5 g and female 60-79 g (*certhia*), male 50-66 g and female 52-71 g (*concolor*). Relatively large, slim woodcreeper with long tail, medium-length bill straight and flattened with wide base, slightly hooked tip; head feathers of male frequently erected into somewhat shaggy crest. Nominant race has brownish face with fine barring, weak supercilium, pale lores and auriculars; olive-brown above, forehead to nape darker, crown feathers with golden-buff shaft streaks and black tips, slightly paler and more rufescent back and wing-coverts weakly barred with blackish; remiges, rump

## Family DENDROCOLAPTIDAE (WOODCREEPERS) SPECIES ACCOUNTS

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in lowland forest almost throughout range; isolated population of race *medius* in NE Brazil very rare, and possibly extirpated, in what little habitat remains. May be less common at upper elevational limit at base of tepuis, where recorded once to 1200 m in E Colombia, but possibly more regular to 1400 m in S Venezuela; occurs only locally along E slope of Andes to 900 m in Ecuador. Estimated densities at sites in mid-successional and late-successional forest on floodplain in SE Peru 1-5 pairs/100 ha; those in *terra firme* forest varied from 0.6 pairs/100 ha in SE Peru to 4-5 pairs/100 ha in Amazonian Brazil. Unlike truly "professional" ant-followers, this species can exist in, or colonize, both small forest fragments and selectively logged forest, at least for several years, provided that continuous forest is nearby. An indicator of tropical lowland evergreen forest in NE Brazil and in N & S Amazonia.

## 22. Hoffmann's Woodcreeper *Dendrocolaptes hoffmannsi*

**French:** Grimpar de Hoffmanns **German:** Paräbaumsteiger **Spanish:** Trepatroncos de Hoffmann

**Taxonomy.** *Dendrocolaptes hoffmannsi* Hellmayr, 1909, Calama, Rio Madeira, Rondônia, Brazil. Apparently forms a superspecies with *D. picumnus*, suggested as conspecific by some authors, and with *D. platystris*, being closely allied to both based on vocal and behavioural characters combined with biogeographical patterns. Allied with *D. sanctithomae* and *D. certhia* in one phylogenetic study on basis of anatomical characters. Monotypic.

**Distribution.** S Amazonian Brazil, S of Amazon, from R Madeira E to R Tapajós and its headwaters at R Juruena, S at least to Rondônia and SW Mato Grosso (S limit of range unclear). Alleged records farther E (to lower R Xingu) appear to refer to mislabelled specimens.

**Descriptive notes.** 28-29 cm; male 78.5-86 g, female 74-89 g. Large but relatively slim woodcreeper with long tail, laterally compressed, straight bill of medium length. Adult has dark buffy face with indistinct scaling, diffuse supercilium; strongly rufescent forehead and crown, blending to rufous-brown on nape and back, and cinnamon-rufous to rufous-chestnut on wings, rump and tail, crown feathers with obscure buffy shaft streaks and obvious black tips (producing weakly barred pattern), back with a few, fine shaft streaks but upperparts and wings largely unmarked; primary tips dusky; throat and underparts dull buffy with olive cast,

tending more towards ochraceous on belly, breast with faint buffy shaft streaks (usually fine), belly and flanks barred narrowly and inconspicuously with dusky; underwing-coverts ochraceous buff; iris light grey to brown; bill dusky grey to black, lower mandible sometimes paler; legs and feet grey. Distinguished from race *concolor* of *D. certhia* mainly by rufous cap, black bill, fine streaking on breast. Sexes similar. Juvenile is more reddish above, more ochraceous below, with tendency towards dark spotting along edges of breast feathers resulting in subtle mix of streaking and barring; some birds more boldly streaked below, possibly reflecting immaturity. Voice. Song, given chiefly at dawn, but probably also at dusk, from perch high in forest, a rolling series of c. 20 similar notes on roughly same pitch, very like that of *D. picumnus* but possibly shorter in total duration. Various calls described as "wh kai", "kaihh-jeep" and snarling.

**Habitat.** Humid forest, both *terra firme* and on floodplains. Generally in interior of primary forest, but visits edges and possibly also older second growth. Amazonian lowlands, to c. 300 m.

**Food and Feeding.** Diet undescribed; presumably mostly arthropods. Regular attendant at army-ant swarms, and probably associates at least at times with mixed-species flocks. Forages primarily from understorey to subcanopy. Brief observations suggest that diet and foraging behaviour over ants are similar to those of *D. picumnus*; most observations over swarms have involved single individuals. Waits on large vertical trunks, at heights below 2 m, for prey flushed by ants; takes items largely by sallying to palm fronds and leaves, less frequently to ground, trunks, vines or mid-air; gleans prey from same substrates slightly less frequently. Competes with large antbirds (Thamnophilidae) when near ground, where forages somewhat less frequently than does *D. picumnus* near Manaus, Brazil (in absence of large antbird competitors). Occasionally supplanted by more aggressive *Xiphorhynchus guttatus*, and, in turn, attacks the smaller *Dendrocincla*. Away from ant swarms, remains relatively high up (6-13 m in one study) and on large trunks. That gleaning may be more important in this species than in some congeners suggested by its comparatively slimmer bill relative to those of most others.

**Breeding.** Nothing published on nest, eggs or any other aspect of breeding biology. One bird in breeding condition in late Sept in Mato Grosso.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. A rarely seen and little-known species. Uncommon to fairly common at some sites, but possibly local; occurs in a region that is ornithologically poorly known. Does not range so far S as do many endemics of the Madeira/Tapajós region; S limit of range unknown, but unrecorded in Bolivia. Recent observations mainly from two sites: Borba, on R Madeira, and Amazonia National Park, on R Tapajós, but is probably widespread in area

between the lower reaches of these two rivers. Believed to be highly sensitive to human disturbance. An indicator of tropical lowland evergreen forest in S Amazonia.

**Bibliography.** Anon. (2003a, 2003c), Cory & Hellmayr (1925), Dubs (1992), Haller (1992), Hellmayr (1909a, 1910), LeCroy & Sloss (2000), Marantz (1997), Meyer de Schauensee (1966), Oren & Parker (1997), Pinto (1938, 1978), Ridgely & Tudor (1994), Sick (1993), Sneath (1914, 1926), Stotz *et al.* (1996), Willis (1982d).

## 23. Black-banded Woodcreeper

### *Dendrocolaptes picumnus*

**French:** Grimpur varié **German:** Dunkelschnabel-Baumsteiger **Spanish:** Trepatroncos Variable  
**Other common names:** Cross-barred Woodcreeper (*transfasciatus*); Pale-billed Woodcreeper (*“pallascens”* group)

**Taxonomy.** *Dendrocolaptes Picumnus* M. H. K. Lichtenstein, 1820, “Cayenne”.

Apparently forms a superspecies with *D. hoffmannsi* and *D. platyrostris*, to which closely allied based on vocal and behavioural characters combined with biogeographical patterns. Races form three groups, occurring in distinct biogeographical regions and differing in morphology: “*picumnus* group”, also including *validus* and strikingly different *transfasciatus* (latter sometimes treated as a full species), is primarily Amazonian, but apparently with recent invasion into N Andes and mountains of S Central America (*multistrigatus* and *costaricensis*); montane “*puncticollis* group” (also including *seileri* and *olivaceus*) occurs at fringes of species’ range; “*pallascens* group” (with *casarezi*), found in Chaco region, is regarded by some as constituting a separate species. Single record from N Argentina (E Formosa) may be referable to race *pallascens*. Described race *veraguensis* (W Panama) considered inseparable from *costaricensis* and synonymized with it; purported race *extimus*, known only from type locality (R Alto Paraná, in SE Paraguay), is inseparable from *pallascens* and described from a series of specimens that were probably mislabelled; larger size upon which race *casarezi* described not supported by recent study. Has apparently hybridized intergenerically with *Hylexetastes stresemanni* in W Brazil, one of few cases of possible hybridization in suboscines. Ten subspecies recognized.

#### Subspecies and Distribution

*D. p. puncticollis* P. L. Sclater & Salvin, 1868 - highlands of S Mexico (Chiapas), C Guatemala and W Honduras.

*D. p. costaricensis* Ridgway, 1909 - subtropical to lower temperate zones of highlands in C & SE Costa Rica and Pacific slope of W Panama.

*D. p. multistrigatus* Eyton, 1851 - subtropical to lower temperate zones in Perijá Mts and Andes of Colombia (S to Cauca) and NW & W Venezuela (Zulia, N Barinas S to Táchira).

*D. p. seileri* Hartert & Goodson, 1917 - tropical and subtropical zones in foothills and highlands of N Colombia (Santa Marta region) and coastal range of N Venezuela (Falcón E to Sucre and N Monagas).

*D. p. validus* Tschudi, 1844 - lowlands and foothills of W Amazonia, both N & S of Amazon, in SE Colombia, E Ecuador, E Peru, N Bolivia and W Brazil (I: to R Negro and R Madeira, and S to Mato Grosso).

*D. p. picumnus* M. H. K. Lichtenstein, 1820 - lowlands of N Amazonia, N of Amazon, in S & E Venezuela, the Guianas and N Brazil (R Negro E to Amapá).

*D. p. transfasciatus* Todd, 1925 - Amazonian Brazil, S of lower Amazon, from R Tapajós E to R Xingu and S to N Mato Grosso.

*D. p. olivaceus* J. T. Zimmer, 1934 - E foothills of C Bolivian Andes (La Paz, Cochabamba, Santa Cruz).

*D. p. pallascens* Pelzel, 1868 - Chaco region of E Bolivia, S Brazil (W Mato Grosso, W Mato Grosso do Sul) and W Paraguay.

*D. p. casarezi* Steullet & Deauter, 1950 - subtropical zone of E Andean foothills in NW Argentina (Jujuy, Salta, Tucumán).

**Descriptive notes.** 24-30.5 cm; male 67-89 g and female 72-98 g (Amazonia), male 61-62 g and female 59-64 g (Central America), male 47-73 g and female 48-73 g (“*pallascens* group”). Large, slim woodcreeper with long tail, nearly straight bill of medium length. Nominant race has dusky face and neck with buffy to tawny streaking, diffuse supercilium and eyering; dark brown forehead, crown and nape that contrast with olive-brown back, scapulars and wing-coverts, crown feathers with darker edges and buff to tawny streaking that expands distally, back with fine shaft streaks and indistinct dark barring, wing-covert

feathers with pale shaft streak and dark subterminal band; rump, wings and tail rufous-chestnut, primary tips dusky; throat whitish to deep buff with indistinct streaking or mottling; breast boldly streaked buff on olive-brown background with underlying pattern of spotting or barring, belly, flanks and undertail-coverts buffy-brown with bold black barring; underwing-coverts slightly brighter, barred blackish; iris dark brown; bill black, edges and base of lower mandible pale horn, grey or brown; legs and feet brown to greenish-grey. Distinguished from often sympatric and similarly plumaged *Xiphocolaptes promeropirhynchus* by smaller size, smaller and straighter bill, and lack of dark malar-stripe. *Dendrocolaptes certhia*, sympatric in Amazonia, is smaller and lacks streaking on crown and breast. *Dendrocolaptes hoffmannsi* nowhere sympatric, similar only to “*pallascens* group” but has dark bill. Races most similar to *D. platyrostris* are those in Amazonia, which are larger and generally have a brownish crown; race *transfasciatus* has black crown but streaking on breast is bolder and black bars on belly do not cross feather shafts. No species of *Xiphorhynchus* is barred below, and *Xiphocolaptes major* is much larger and heavier-bodied than is sympatric race *pallascens*. Female differs from male only in larger size, sleeker head plumage. Juvenile is similar to adult, but plumage fluffier, throat more sealy, streaking on back and underparts bolder, pattern of spotting underlying breast streaks bolder, underparts more weakly barred, and crown darker overall, more spotted than streaked and often with tips of feathers darker. Racial variation complex but three groups emerge based on plumage patterns: within “*picumnus* group”, race *validus* is very similar to nominate, differing in brownish (rather than black) upper mandible that contrasts with paler lower mandible, lacks barring above, breast more cleanly streaked and without underlying barring; *transfasciatus* is distinctive, crown blackish, more boldly streaked with golden above and with white below, back and wing-coverts weakly barred, belly spotted rather than barred (black bars on feathers not crossing shafts); *multistrigatus* is smaller than previous races, less obviously streaked above, more finely barred below, streaking on breast more extensive but narrower; *costaricensis* closely similar to *multistrigatus* but underparts more extensively barred, breast less extensively streaked and with underlying pattern of spotting. Races of “*puncticollis*

group” with narrow, black-bordered streaks on otherwise unmarked breast, barred portion of belly more limited in extent; *puncticollis* has crown blackish and only finely streaked, bill much longer and slimmer than any other *Dendrocolaptes*; *seileri* is similar to *puncticollis* but bill shorter and paler, crown browner, and streaking below more extensive (continuing to upper belly); *olivaceus* is closely similar to *seileri* but underparts more olivaceous, crown lighter brown, back more strongly streaked, and streaking on both crown and breast more buffy (less whitish). Members of “*pallascens* group” differ strikingly from others by rufescent coloration with minimal streaking on both crown and breast, bill pale olive to bluish-horn, belly indistinctly barred; coloration below markedly variable individually, from bright rusty to plain brown; *casarezi* differs from *pallascens* only in slightly larger size, longer bill. **Voice.** Song, given primarily at dawn and dusk (rarely during day), in Amazonia a loud series 2-5 seconds long of 15-20 rapidly delivered liquid notes, usually on same pitch, sometimes falling away at end, “kie-ie-ee-...ie-ee-eu-eu-er”, “glü glü glü glü glü” or “whi-whi-whiwhiwhi”, differs from *D. certhia* song mainly in constant frequency and more notes; in N Venezuela similar but noticeably descending, slower, with fewer notes; in S Mexico described as high-pitched, descending chatter; when agitated, songs often run together into long strings of notes. Both members of pair sing, often near roost sites from concealed perch in upper levels of forest. Calls include short whinny, nasal “wrenh” with upward inflection, simple “oi” falling in pitch, squealing “squeeh” during fights, snarling “chauh-hh-eesk” in alarm, grunting series of “uk-uk-uk” at competitors, various rattles; soft “peep-songs” by fledged young.

**Habitat.** Occurs in a complex array of forested habitats, some races exclusively in tropical lowlands, others in upper tropical to lower temperate zones of highlands. In Amazonian lowlands frequents primarily terra firme forest and floodplain-forest, less often flooded forest, forests on sandy soils, or forested savanna; very rarely, enters mangroves. Elsewhere, occurs in a variety of deciduous and semi-deciduous forests (both dry and humid), humid evergreen forest, cloudforest; also pine (*Pinus*) and pine-oak (*Pinus-Quercus*) woodland in N of range (*puncticollis*). Frequents chiefly interior of mature forest, often with relatively open understorey; regularly also in older second growth and forest edge, and rarely adjacent plantations or trees within clearings. Amazonian forms to c. 1900 m along E slope of Andes in Ecuador and to 1300 m in Peru; montane forms most frequent at middle elevations, but to 2800 m in South America and 3000 m in Central America; 1000-3000 m (rarely to 750 m in winter) in S Mexico to Honduras, 900-2100 m in Costa Rica and Panama, 1300-2800 m in Colombian Andes, and 450-2700 m in N Venezuela.

**Food and Feeding.** Diet mostly arthropods, but small vertebrates also taken. Over ants, preys largely on cockroaches (Blattodea), katydids (Tettigoniidae), grasshoppers (Acrididae) and winged ants, also on various types of beetle, scorpions, spiders, centipedes (Chilopoda), crickets (Gryllidae), caterpillars, and other invertebrates. Small lizards apparently most common vertebrate prey, but frogs also taken. Stomach contents included cockroaches, *Camponotus* ants, bees, beetles, scorpions, snails. Most prey relatively small; larger items of 30-50 mm also regularly taken, with records of several centipedes and a grasshopper longer than 100 mm, these usually battered against tree trunks before being swallowed. Amazonian populations forage extensively in association with swarms of army ants (primarily *Eciton burchellii*), but also encountered regularly alone and occasionally with mixed-species flocks. Montane birds rarely seen at all, but probably rely to much lesser degree on ants. Over 85% of encounters at a Guianan site involved solitary birds, with only 7% each for birds with flocks or over ants; likewise, only 5% of birds observed at site in SE Peru were with flocks. Usually singly or in pairs, sometimes in threes; rarely, 4-5 birds seen at same ant swarm following breeding season. In Amazonia, follows ant swarms almost daily and wanders widely in search of them; as most ant-following birds, active at swarms for much of day. Usually forages in undergrowth over swarms, where activity concentrated within 6 m of ground, but regularly follows ant probes into subcanopy; c. 25% of foraging within 1 m of ground (especially 10-40 cm), with sallies more successful from lower perches than from higher ones; excluded from optimal foraging locations within 3 m of ground by larger *Hylexetastes perrotii*. Perches mostly on near-vertical trunks 5-50 cm in diameter, waiting for extended periods of time before sallying up to 2 m (occasionally to 3 m, rarely farther) to capture prey. Nearly 30% of prey at ant swarms taken from ground (slightly less in presence of *Hylexetastes*, more in its absence), with 23% taken from foliage, especially palm fronds, and 8% in air; in another study, over 50% of prey picked from trunks, and majority of rest taken from foliage. Gleaning or pecking used more frequently than by *D. certhia*, less than by *D. sanctithomae*; most gleaned prey taken from trunks, logs or vines, very little from leaves, twigs, the ground or other substrates. Seen to inspect palm fronds, rotten snags, holes in trunks, epiphytes, and termite (*Isoptera*) nests, but rarely visits downed logs, inspects loose debris, rummages in leaves, or digs into dead wood or into termite or bee nests. Regularly attracted to emergences of winged ants or activity associated with ant swarms. Pair-members often antagonistic towards each other, with female apparently dominant over male; additional individuals generally chased off soon after appearance at swarms. Agonistic encounters with conspecifics and other dendrocolaptids frequent. Regularly supplants or displaces both antbirds (Thamnophilidae) and smaller woodcreepers, especially *Dendrocincla* species (*D. fuliginosa*, *D. merula*) and *D. certhia*, less frequently *Xiphorhynchus* species; supplanted by larger dendrocolaptids, especially *Hylexetastes perrotii* and *Nasica longirostris*, and occasionally by smaller *Dendrocincla* and *Xiphorhynchus* (especially highly aggressive *X. guttatus*). Away from ants, often forages at mid-levels or in subcanopy, where prey both gleaned from bark or taken by sallying; often sluggish and rather inconspicuous.

**Breeding.** Breeds in May-Jun in N Venezuela and Mar-May in Guyana; nest-building in Apr in Costa Rica; fledged young in Nov-Dec in Colombian Andes and early Jul to early Jan near Manaus (Brazil); birds in breeding condition in mid-Feb in Surinam, Apr in Mexico, late Sept in Amapá (Brazil) and late Jul in Paraguay; in non breeding condition in Mar at Cerro de la Neblina (S Venezuela), late Apr in Amapá and late Sept in Mexico. Molt appears to follow breeding, Jun-Dec (Central America) and Nov-Feb (C Amazonia). Paired throughout year. Nest in tree cavity; mean territory size 21 ha in mature floodplain-forest in SE Peru. Clutch 2 white eggs, 29 × 21 mm; parental care and territory defence apparently by both parents; young remain with parents for 3-4 months after fledging.

**Movements.** Resident in most of range, but may move downslope after breeding at N sites.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in most of Amazonian range, in N Central America and in parts of the Chaco; scarce to rare in most of montane range (Costa Rica, Panama, Colombia, Venezuela, Bolivia), especially near upper elevational limit; also rare along S fringe of Amazonia and in S Paraguayan Chaco. Densities in C Amazonian Brazil estimated at 1-8 pairs and additional 1-4 floaters/100 ha (slightly higher following breeding season); in SE Peru 2 pairs/100 ha in mature floodplain-forest, but only 0-25 pairs/100 ha in adjacent late-successional forest. Pairs occupy somewhat overlapping territories, from which they wander well into neighbouring territories in search of ant swarms. At least some populations believed to require nearly continuous forest, and thus highly sensitive to human disturbance. Disappears from small forest fragments, but numbers may be only slightly reduced in larger fragments and selectively logged forest. Occasionally crosses barriers of unsuitable habitat to recolonize fragments that still harbour active ant swarms.

## 24. Planalto Woodcreeper

### *Dendrocolaptes platyrostris*

**French:** Grimpar des plateaux    **German:** Planaltobaumsteiger    **Spanish:** Trepatroncos Oscuro

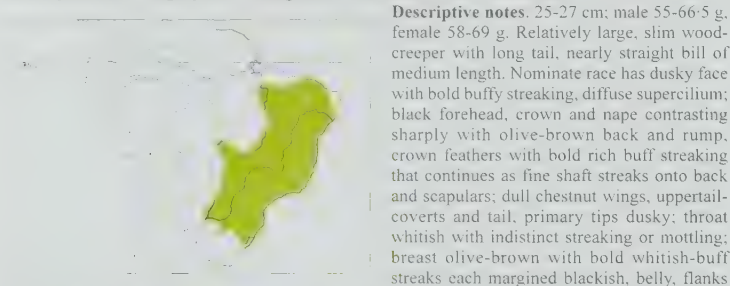

**Taxonomy.** *Dendrocolaptes platyrostris* Spix, 1824, Rio de Janeiro, Brazil.

Apparently forms a superspecies with *D. hoffmannsi* and *D. picumnus*, and sometimes considered conspecific with latter on grounds of morphological similarity. Race *intermedius* exhibits some vocal differences from nominate, but plumage characters of the two intergrade where they come into contact in SE Brazil (E São Paulo, S Goiás, Minas Gerais) and S Paraguay. Two subspecies recognized.

#### **Subspecies and Distribution.**

*D. p. intermedius* Berlepsch, 1883 - NE, C & SC Brazil, from SE Pará (Marabá), Maranhão, Ceará and W Pernambuco S to S Mato Grosso, Mato Grosso do Sul, Minas Gerais and Bahia; also adjacent E Paraguay (rarely farther W).

*D. p. platyrostris* Spix, 1824 - E & SE Brazil (S Bahia and E Minas Gerais S to Rio Grande do Sul), also adjacent SE Paraguay and NE Argentina (Misiones, N & E Corrientes, E Formosa, E Chaco).

and undertail-coverts buffy-brown, finely barred blackish; ground colour both above and below highly variable, from olive to reddish-brown, even in birds from same locality; iris brown, orbital skin yellow; bill black, lower mandible sometimes light or brownish at tip; legs and feet greenish-grey to dark brown or black. Distinguished from sympatric and similarly plumaged *Xiphocolaptes albicollis* by smaller size, smaller bill, slimmer body, more heavily streaked back, and lack of boldly white throat. Races of *D. picumnus* that are most similar occur in Amazonia, where size larger and crown brownish rather than black (except *D. p. transfasciatus*, which has breast more boldly streaked and belly with black bars that do not cross feather shafts). Female differs from male in slightly larger size, sleeker head plumage. Juvenile undescribed. Birds from far southern part of range of nominate race average darker both above and below. Race *intermedius* is paler and more cinnamon overall, with crown dusky brown or olive, back virtually unstreaked, and wings, rump and tail slightly lighter, more rufous. Plumage characters, especially coloration of crown, intermediate in region of contact between nominate and *intermedius* (E São Paulo, S Goiás, Minas Gerais & S Paraguay). Voice. Song, given mostly at dawn and dusk, a series 3-8 seconds long of relatively shrill “whik”, “weck” or “chree” notes at c. 5 per second, notes often on same pitch, but sometimes rising or falling slightly, and fading towards end, e.g. “Ji.ji.ji.ji.jie.je.je...” or “hee, hee, he, he, hey,

hay, huh”, overall pattern similar to that of *D. picumnus* but possibly shriller, duration longer, and notes given more rapidly; when agitated, songs often run together into long strings of notes; *intermedius* song a shorter series of “yourit” or “urit” notes that recalls song of *D. sanctithomae*. Various calls include rattling, a grunting “i-i-i”, and other “squirrel-like” grunts.

**Habitat.** Primarily humid lowland and montane forests along Atlantic coast; race *intermedius* largely in semi-deciduous woodland, Mauritius palm swamps, and gallery forest within *coatinga*, *cerrado* and Chaco regions (occurs both farther N and farther inland, where climate on average drier). Frequents interior of mature forest, second growth and edges, but seems to avoid borders, at least at some sites; occasionally visits gardens, plantations, and even clearings adjacent to forest. Lowlands into foothills, regularly to 1300 m, rarely to 2100 m.

**Food and Feeding.** Diet mostly arthropods, but small vertebrates and occasionally vegetable matter also taken. Stomach contents included spiders, a variety of ants and beetles, bugs (Hemiptera), earwigs (Dermaptera), flies, ants, lepidopteran larvae, and dragonflies (Odonata); observed also to take bees, and even a small frog. Regularly associates with mixed-species flocks during non-breeding season, and frequently with army-ant swarms, but apparently less dependent than its congeners on either; seemingly less conspicuous and less often with flocks when breeding, and significantly more frequent in flocks with Cinereous Antshrike (*Thamnomanes caesioides*) than in those without them at one site in Espírito Santo (Brazil); considered a “professional” ant-follower by some authors, but regularly seen away from ants (more so than *D. picumnus*). Often occurs singly, sometimes in pairs, at ant swarms, where forages mostly in undergrowth, with most prey taken in sallies up to c. 1 m from perch, often to low foliage or ground. Over swarms, female dominant over male; supplants smaller antbirds (Thamnophilidae), tanagers (Thraupidae), also other dendrocolaptids (especially *Dendrocincla fuliginosa* and *D. turdina*), but in turn is supplanted by *Xiphorhynchus guttatus*. Away from ants, forages from mid-levels into subcanopy, or even canopy, usually by hitching up trunks and sallying out after (or less frequently, pecking at) prey from surface of vines, foliage, or medium-sized trunks and limbs; sallying likely important over ant-swarms, but pecking or gleaning probably more important away from ants. Prefers trees with rough bark over those with smooth bark, and trunks covered with mosses over those covered with lichens; occasionally peers into bromeliads.

**Breeding.** Little published on breeding biology. Birds with worn feathers in Sep (Minas Gerais, Brazil). Birds in breeding condition or with brood patches in Oct-Dec and moulting flight-feathers in Nov-Mar in S Brazil, also feeding nestlings in early Oct (São Paulo); in breeding condition in Nov in Paraguayan interior; nest-building observed in mid-Sept in NE Argentina, where only 2 of 23 specimens in late Mar to mid-Apr approaching breeding condition. Two nests described, both with entrance 6-8 m up in natural cavity in trunk, one in laurel (*Nectandra*), other in *Centroleobium tomentosum* growing within open wood of botanical garden, with entrance measuring 40 × 7 cm; bark fragments from nearby trees (*Fagara rhoifolia*, *Diatenopterix sorbifolia*) observed being taken to latter nest. Clutch size and eggs not documented; at one nest both members of pair cared for young, and food-delivery rate varied from 2-5 to 1-6 visits per hour (more frequent in morning, less so during midday), most food items were spiders. One ringed individual recaptured after more than 6 years.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in remaining habitat in core of Brazilian range and in Alto Paraná of SE Paraguay; scarce to rare at fringes of range, e.g. in rest of Paraguayan range and at some Brazilian sites (N Pantanal, SW Rio Grande do Sul). Occurs in Serra dos Órgãos, Itatiaia and Aparados da Serra National Parks, in Brazil. Suggested to be only moderately sensitive to human disturbance, which may explain continued presence at many somewhat degraded sites. In addition to primary forest, occurs in both selectively logged forest and tall second growth. Although capable of surviving at least in the short term in forest fragments of moderate size, tends to disappear from those smaller than 200 ha, and populations may be depressed even in larger fragments lacking army ants; disappeared from an isolated fragment of 145 ha in less than 15 years, but known to have survived in moderate numbers in much smaller fragments over a longer period of time. An indicator species for gallery forest in C South America.

# Genus *XIPHORHYNCHUS* Swainson, 1827

## 25. Lesser Woodcreeper

### *Xiphorhynchus fuscus*

**French:** Grimpard brun **German:** Blasskehl-Baumsteiger **Spanish:** Trepatroncos Enano

**Taxonomy.** *Dendrocopus fuscus* Vieillot, 1818, near Rio de Janeiro, Brazil. Formerly placed in genus *Lepidocolaptes*, but recent molecular studies indicate that it is better placed in present genus, as suggested also by both behavioural observations and morphological characters. Molecular data suggest that it is apparently sister to a combined *X. spixii*/*X. elegans* and *X. pardalotus*/*X. ocellatus* clade. Four subspecies recognized.

#### Subspecies and Distribution.

*X. f. atlanticus* (Cory, 1916) - NE Brazil from Ceará and Paraíba S to Alagoas.  
*X. f. brevisrostris* (Pinto, 1938) - arid interior of NE Brazil (W Bahia).  
*X. f. tenuirostris* (M. H. K. Lichtenstein, 1820) - coastal E. Brazil from C. Bahia S to R. Doce (Espírito Santo).  
*X. f. fuscus* (Vieillot, 1818) - SE Brazil from S. Goiás, E Minas Gerais and Espírito Santo (R. Doce) S to NE & C. Rio Grande do Sul, also S & SE Paraguay and NE Argentina (Misiones).

**Descriptive notes.** 15-18.5 cm; 15.5-25 g. Small, slim woodcreeper with proportionately large head, steep forehead, relatively long, slim, somewhat decurved bill. Nominative race has broad creamy to yellowish-buff supercilium, contrasting with well-defined dusky patch on auriculars, often pale eyering; crown and nape blackish-brown, forehead and crown with small but prominent yellowish-buff to cinnamon spots, these becoming more streak-like on nape and side of neck; back and wing-coverts olive-brown to reddish-brown, streaks of nape extending (often weakly) to upper back, where thinly bordered blackish; rump, remiges

and tail rufous-chestnut, outer webs of primaries darker, tips blackish; unmarked creamy-yellow throat blends to smoky brown on breast and belly, breast, sides and upper belly boldly marked with elongate scales or rounded streaks each with blackish-brown border, eventually passing to weak streaking on a clay-brown background; undertail-coverts and underwing-coverts cinnamon; iris dark brown; upper mandible blackish-brown to dark horn (often darker base), lower mandible pinkish to white, sometimes darker tip; legs and feet olive-grey to bluish-grey. Distinguished from *Lepidocolaptes squamatus* and *L. falcinellus* by smaller size, spotted crown, more extensively streaked back, underparts buffier with less boldly margined streaks. Sexes similar. Juvenile differs from adult in more weakly defined ventral spotting, apparently shorter bill. Race *tenuirostris* is similar to nominate but larger, with buff spots below having weaker, more brownish edges; relative to both nominate and *tenuirostris*, *atlanticus* is much brighter ochraceous below, with more obvious dark brown edgings on lower throat, and weaker borders to broader streaks, together resulting in more blurred appearance, bill possibly longer; *brevisrostris* is palest race, pale yellowish below and more cinnamon on wings and tail, has shorter bill than *atlanticus*. **VOICES.** Song a sharp rattle of 3-6 seconds, with several slow "chip" notes accelerating to rapid trill, and slowing again at end, e.g., "kwip-kwip-kwip-kwip-kwip-kwip," or "chit, chit, chit, chee-ee-ee-ee-ee-ee-ee, chit, chit-chit"; song of race *atlanticus* noticeably different in quality, initial notes sharper and fewer, middle trill clearly ascending. Calls include doubled "peep, peep" and single "speel" or "wik".

**Habitat.** Variety of forest types. Mainly lowland rainforest and humid montane forest in much of range; also *Araucaria* forest in S, and semi-deciduous and gallery forests at drier sites farther inland. Frequents interior of mature forest, older second growth, forest edge; occasionally younger second growth and gardens adjacent to forest. Occurs in both tropical and subtropical zones, primarily in lowlands and foothills, regularly to 1200 m; less frequently in mountains to 1500 m, possibly higher.

**Food and Feeding.** Diet predominantly, if not exclusively, arthropods. Stomach contents of adults in one study mostly beetles (80% of diet), but also cockroaches (Blattodea; 14%) and ants (6%); in another study mostly spiders and various types of planthoppers (Homoptera) and bugs (Hemiptera), with lesser numbers of beetles, ants, Lepidoptera, and a pseudoscorpion. Encountered alone and in association with mixed-species flocks in about equal frequency; less frequently with army-ant swarms. A regular flock associate, both singly and in pairs, and sometimes considered a core species, together with White-eyed Foliage-gleaner (*Automolus leucophthalmus*) and Red-crowned Ant-tanager (*Habia rubica*); tends to drop out of flocks during breeding season; significantly more frequent in flocks with Cinereous Antshrike (*Thamnomanes caesioides*) than in those without them at one site in Espírito Santo (Brazil). Forages on trunks, less frequently branches, from understorey to mid-levels, occasionally into subcanopy or even canopy; usually below 5 m, and almost always within 15 m of ground. Despite preference for using larger trees than average, most foraging is on relatively slim sections of trunks (mean diameter less than 15 cm in one study). Rather high degree of overlap with both larger *Xiphocolaptes albicollis* and smaller *Sittasomus griseicapillus* in height and diameter of trunks used at one site. Shows significant preference for trees with rough bark, and trunks covered with mosses preferred to those covered with lichens; also uses bromeliads and other epiphytes. Hitches up trunks, peering at vines, epiphytes, clusters of dead leaves, or branches; often ascends only short distance before moving on to next tree. Gleaning and pecking are most common techniques. Relatively infrequent at ant swarms (*Eciton burchelli*, less frequently *Labidus praedator*), where forages mostly between 0.4 m and 9 m above ground using techniques similar to those used away from ants, but has also been seen to sally to a nearby leaf, and plunge to capture falling prey.

**Breeding.** Gonadal condition, and presence of brood patches and cloacal protuberances, suggest breeding in Sept-Dec throughout range; nests with eggs in Oct and with nestlings in early Sept in Brazil, and juveniles in late Oct and early Nov in Brazil and Paraguay. Nest in tree cavity, one in young second growth and another in small fragment of semi-deciduous forest; only one nest de-

scribed in detail, in trunk of small leguminous tree (Mimosoideae), entrance a slit 75 × 3.5 cm, lower end 1 m above ground, chamber 10 cm below entrance, nest cup lined with small dried leaves and bark fragments. Clutch 2 white eggs, rarely 3, average 25 × 18 mm; 5 males in breeding condition lacked incubation patch, suggesting that male may not share in incubation; nestlings were of different sizes and in different stages of feather development, suggesting asynchronous hatching; ventral feathers appear to be last to develop; stomach contents of nestlings mostly spiders and orthopterans, also a beetle larva. An individual ringed in São Paulo recaptured nearly 4 years and 6 months later.

**Movements.** Presumably resident throughout range; significantly lower encounter rates in non-breeding season at S limit of range in Brazil (Rio Grande do Sul) suggest possibility of either local movement or reduced activity as a result of colder weather.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout much of Brazilian range, but rare to uncommon along S & SW fringes; uncommon and local in Rio Grande do Sul. Uncommon and local in Paraguay, especially in SW (Neembucú region). Has been suggested to be highly sensitive to human disturbance, but able to survive in moderate numbers in selectively logged forest, tall second growth, and fragments of moderate size. Though sometimes fairly common in fragments of 40-60 ha, especially when these connected to continuous forest, numbers often much reduced in smaller, more isolated patches, and usually disappears altogether from fragments smaller than 20 ha; was also absent from a 200-ha fragment of early-successional forest. Data from one study indicate that borders may be avoided at some sites. Home range suggested to be 250-300 m across at one site.

## 26. Tschudi's Woodcreeper

### *Xiphorhynchus chunchotambo*

**French:** Grimpard de Tschudi **German:** Bartstreif-Baumsteiger **Spanish:** Trepatroncos de Tschudi

**Taxonomy.** *Dendrocolaptes Chunchotambo* Tschudi, 1844, Chanchamayo Valley, Junín, Peru. Molecular data support placement as sister to clade including *X. ocellatus* and *X. pardalotus*. Considered conspecific with *X. ocellatus* by most recent authors, but differs morphologically and genetically, supporting treatment by earlier authors as a separate species; race *napensis* allied with *X. ocellatus* by some authors, but external morphology supports original treatment as a race of present species. Three subspecies recognized.

#### Subspecies and Distribution.

*X. c. napensis* Chapman, 1924 - lower Andean slopes and adjacent Amazonian lowlands from S. Colombia (SE Nariño, W Caquetá) S to NE Peru (S to R. Marañón).  
*X. c. chunchotambo* (Tschudi, 1844) - lower Andean slopes in E & NE Peru (S of R. Marañón to Ucayali and Junín).  
*X. c. brevisrostris* J. T. Zimmer, 1934 - Andean foothills and adjacent lowlands in SE Peru and N & C Bolivia (La Paz and W Beni E to W Santa Cruz).

**Descriptive notes.** 21-24.5 cm; 30-38 g. A slim, medium-sized woodcreeper with bill relatively long, slim and noticeably decurved distally. Nominative race has face finely streaked whitish-buff and dark brown, supercilium weak or lacking; blackish-brown crown and nape with small teardrop-shaped buff spots, smaller on forehead and larger on nape; back and wing-coverts olive-brown, with fine buff streaks over much of back; rump and remiges rufous-chestnut, tail somewhat darker, edges of primaries olive-brown, tips dusky; throat pale buff to buffy whitish, blackish feather edges on lower throat (producing a scaly appearance), blackish malar stripe; underparts olive-brown, slightly paler than above, upper breast with bold teardrop-shaped buff spots with blackish edges, grading into elongate buff streaks on lower breast and belly that fade on lower belly and flanks, and reduced to a few fine shaft streaks on undertail-coverts; underwing-coverts ochraceous; iris ashy brown to dark brown; bill dark brown to blackish, lower mandible pale greyish; legs and feet greenish or grey to brownish. Very similar to *X. ocellatus* but crown spotted rather than streaked, back finely but conspicuously streaked, lower throat with bolder pattern of scaling, dark malar stripe, underparts extensively streaked instead of with limited spotting, throat paler, and overall coloration darker, more olivaceous. Differs from races of *X. elegans* in SE Peru (which have similarly weak streaks on back) by buffier throat, larger spotting on breast and different vocalizations; in Bolivia also by shorter, paler bill. Female is like male, but slightly smaller. Juvenile resembles adult, but underparts more heavily spotted, spots more poorly defined. Race *napensis* has crown spots smaller than nominate, streaking on back narrower and more linear, throat more richly coloured and more extensively scaled, belly less distinctly and less extensively streaked; *brevisrostris* is smaller and browner overall than nominate, streaks on back broader and more pronounced, those on underparts broader but more poorly defined, throat paler and largely unmarked, bill paler, slimmer, shorter and more deeply curved. **VOICES.** Song apparently given somewhat intermittently (often only few songs in a bout), primarily at dawn and dusk (less frequently during day, then often partial songs), in E Ecuador described as a fast, descending series of nasal notes with terminal ones sharply emphasized, "whe-whe-whe-whe-whe-chéchécheow"; either the descending series or the emphasized notes sometimes given alone, espe-

On following pages: 27. Ocellated Woodcreeper (*Xiphorhynchus ocellatus*); 28. Chestnut-rumped Woodcreeper (*Xiphorhynchus pardalotus*); 29. Spix's Woodcreeper (*Xiphorhynchus spixii*); 30. Elegant Woodcreeper (*Xiphorhynchus elegans*); 31. Striped Woodcreeper (*Xiphorhynchus obsoletus*); 32. Buff-throated Woodcreeper (*Xiphorhynchus guttatus*); 33. Cocoa Woodcreeper (*Xiphorhynchus susurrans*).

cially when excited. Typical call a sharp, but slightly slurred “kleer!”, also, a series 1-2 seconds long of 7-15 short, squeaky notes, “wik-di-di-di-di-di”, during territorial interaction in SE Peru. **Habitat.** Evergreen forest, primarily on lower Andean slopes, but also in adjacent lowlands. Principally montane evergreen forest and cloudforest, but *terra firme* forest, floodplain-forest and seasonally flooded forest, occasionally wooded swamps, frequented in lowlands; in Bolivia, also semi-deciduous forest in Andean valleys. Seems to prefer interior of mature forest, but also occurs in marginal habitats (mid-successional vegetation, second growth, thickets of *Guadua* bamboo, or forest edge) at some lowland sites. Apparently most common in upper tropical zone of Andean foothills, where it reaches 1800 m.

**Food and Feeding.** Presumably insectivorous, but diet not described in detail. Most prey relatively small (average 0.5 cm), but larger items to 4 cm in length also taken. Singletons, less frequently pairs, regularly associate with mixed-species flocks of forest understory. In one study, individually marked birds spent on average 75% of time with flocks, but total amount variable, 17-83% depending on individual. Daily movement likewise highly variable, with most birds shifting among two or more flocks, despite spending majority of time with primary flock. Tracking data further revealed not only that a “floater” moved over larger home range (despite moving shorter distance each day) than did territorial birds, but also that it spent less time with flocks despite trying to join as many as 8 different ones. Flocks frequented by this species moved through forest at c. 30 m every 10 minutes, significantly more rapidly than those frequented by *X. elegans*; this, however, appears to reflect preference to join flocks moving at this rate, rather than the species itself setting rate of flock movement. Only infrequently encountered at army-ant swarms. Forages while hitching up trunks and branches, primarily from understory to subcanopy. Most prey gleaned or picked from surface of trunks or limbs (c. 75% in one study), also taken by probing into live foliage (less than 10%), or into bark crevices, knotholes, palm fronds and dead leaves (less than 15% combined). Highly aggressive, even for a *Xiphorhynchus*, regularly beginning fights not only with subordinate species, but also with larger, dominant ones (e.g. *X. guttatus* and *X. elegans*); also attacks non-woodcreepers, especially foliage-gleaners of genus *Philydor*. High degree of overlap in diet and substrate use with both *X. elegans* and *X. obsoletus*, resulting in aggression at almost every encounter and interspecific territoriality, producing checkerboard pattern of distribution among flocks in SE Peru. Defends territories including 2 or sometimes more mixed-species flocks of forest understory. Reciprocal turnover of territories with *X. elegans* also documented. Territorial defence requires significant effort, this due in part to defence against dominant *X. elegans*; habitat preferences similar to those of latter, but occurs in lower numbers, with fewer territories per unit area, and often occupies territories that may be smaller than optimal; moreover, a much larger percentage of population appears to consist of non-breeding “floaters”.

**Breeding.** Virtually unknown; nothing published on nest, eggs or even of timing of breeding. Juvenile in early Dec in Peruvian Andes. In one study, courtship behaviour was evident only in pairs maintaining territories that included a minimum of two mixed-species flocks.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout range; at least in Peru, appears to be more common in lower montane forest above c. 1000 m than in adjacent lowlands. Estimated densities in mature floodplain-forest in SE Peru 5 pairs/100 ha, with home range 11-27 ha; in less productive, mid-successional vegetation at same site only 0.5-1.5 pairs/100 ha. As with most flocking species, believed to be highly sensitive to loss and fragmentation of forest. An indicator of upper tropical montane evergreen forest of C Andes.

**Bibliography** Alverson *et al.* (2001), Berlepsch & Leverkühn (1890), Brace *et al.* (1997), Chapman (1924, 1926), Cory & Hellmayr (1925), Dunning (1993), Elliot (1890a), Foster *et al.* (1994), Graves & Gotelli (1993), Hellmayr (1903b), Hilty & Brown (1986), Karr, Robinson *et al.* (1990), LeCroy & Sloss (2000), Meyer de Schauensee (1950a, 1964), Munn (1985), Parker *et al.* (1982), Perry *et al.* (1997), Pitman *et al.* (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Salaman *et al.* (1999), Selater (1871), Servat (1996), Stotz *et al.* (1996), Iacozanowski (1884), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Zimmer (1930, 1934d).

27. Ocellated Woodcreeper

*Xiphorhynchus ocellatus*

**French:** Grimpar ocellé **German:** Augenflecken-Baumsteiger **Spanish:** Trepatroncos Ocellado

**Taxonomy.** *Dendrocolaptes ocellatus* Spix, 1824. Piaui; error = mouth of Rio Madeira, Amazonas, Brazil.

Molecular data support placement as sister to *X. pardalotus*, to the exclusion of *X. chunchotambo*. Considered conspecific with *X. chunchotambo* by most recent authors, but morphological and genetic differences support original treatment as a separate species; race *napensis* treated here within *X. chunchotambo*, despite suggestion by some authors that it may be closer to *X. ocellatus*. Race *weddellii* considered synonymous with nominate by most authors, but genetic and vocal data support treatment as a separate taxon; nomenclature complicated, however, by fact that type specimens of the two were found to be identical when compared directly and, in addition, precise locality data are lacking for both. Range of *lineatocapilla* uncertain; taxon known only from unique type, said to be from Ciudad Bolívar, in C Venezuela, but that evidently erroneous. A thorough taxonomic review is badly needed for this poorly known species. Four subspecies recognized.

**Subspecies and Distribution.**

*X. o. lineatocapilla* (Berlepsch & Leverkühn, 1890) - uncertain, but believed to be from somewhere along R Orinoco, in Venezuela.

*X. o. weddellii* (Des Murs, 1855) - NW Amazonia, N of Amazon, in E & SE Colombia (E Guainia, I Vaupés, S Amazonas), extreme S Venezuela (SW Amazonas), NE Peru and NW Brazil (E to R Negro); may occur W to lowlands of E Ecuador.

*X. o. perplexus* J. T. Zimmer, 1934 - W Amazonia, S of Amazon, in NE Peru (E from lower R Ucayali, possibly from R Huallaga) and W Brazil (E at least to R Tefé, probably to R Purús, and S to Acre).

*X. o. ocellatus* (Spix, 1824) - patchily distributed in S Amazonian Brazil, S of Amazon, from R Purús E to both banks of lower R Tocantins.

**Descriptive notes.** 20-23 cm; 32-42 g. Slim, medium-sized woodcreeper with relatively long, slim bill sharp-tipped and nearly straight. Nominative race has crown and nape dark brown, crown with fine buff streaks, these becoming sparse on nape, with at most a few fine streaks on upper back; back reddish-brown to olive-brown and essentially unmarked; rump and wings cinnamon-rufous, tail similar but darker; throat deep buff, feathers edged darker (especially on lower throat); underparts olive-brown, becoming more rufescent on undertail-coverts, upper breast with large, teardrop-shaped spots of buff only weakly bordered darker, these fading into a few weak streaks on lower breast, with belly largely unmarked; iris dark brown; bill blackish, lower mandible pale grey; legs and feet grey. Easily confused, with most important characters being relatively small size, dark bill, a virtually unmarked back (having at most a few narrow shaft streaks), rich buffy throat usually with scaly pattern, and finely spotted rather than streaked underparts. Differs from *X. chunchotambo*

conspicuously margined dusky; birds tentatively considered under name *weddellii* have spots on breast larger and with darker margins, upperparts warmer brown and more heavily streaked, with streaks sometimes expanding into drops distally, and shoulders more strongly and more deeply rufescent. **VOICE.** Song, usually given only intermittently (often only few songs in a bout), primarily at dawn and dusk (less frequently in day), poorly known and geographically variable: in S Amazonia E of R Madeira a rapid trill that descends slightly before rising at end, “re-e-e-e-e-e-e-e-e-eet”, much like shortened version of *X. obsoletus* song; in S Colombia a rapid trill that descends slightly, then ascends for most of duration, and accelerates at end; also whinnying trill with emphatic final squeak, “r’r’r’r’r’a’a’a’ek”. Most common call a loud, sputtering series of 4-5 notes, “tri-p, pi, pit, pit”.

**Habitat.** Chiefly evergreen forest. At most sites occurs in tall *terra firme* forest, but at some mostly near rivers or swamps (*várzea* at some sites) or in forests associated with sandy soils. Frequents primarily interior of mature forest, less often in disturbed forest, second growth (including younger growth), and forest edge. Patchy distribution possibly related to habitat preferences that are poorly known, and perhaps geographically variable. Chiefly Amazonian lowlands, mostly below 500 m.

**Food and Feeding.** Presumably insectivorous, but diet not described in detail. Single individuals or pairs regularly associate with mixed-species flocks of forest understory; also frequently encountered away from flocks, and occasionally in association with swarms of army ants (principally *Eciton burchelli*). Forages while hitching up trunks and branches, primarily in lower and middle levels of forest; appears to obtain prey largely by gleaning from surface of trunks or limbs, or by peering and probing into bark crevices, epiphytes or clusters of leaves. Over ants, forages in understory within 8 m of ground while quietly hitching up slim trunks 3-25 cm in diameter; attempts at prey capture involved sallies to both the ground and a vine, and gleaning from both a trunk and a nearby leaf. Foraging behaviour typical of others in genus, though possibly more sluggish than *X. pardalotus*, *X. spixii* and *X. elegans*. Rather aggressive at ant swarms; seen to supplant *Dendrocincla merula*, but supplanted by White-breasted Antbird (*Rhegmatorhina hoffmannsi*).

**Breeding.** Specimens in breeding condition in mid-May in E Colombia. No other information published on nest, eggs or any other aspect of breeding biology.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Status not well known; appears to be fairly common to common, but inconspicuous and local, throughout most of range. Believed to be highly sensitive to loss and fragmentation of forest. Encounter and capture rates significantly lower in young second growth than in mature forest at Amazonian sites in Colombia and Brazil; the Brazilian study, however, documented comparable encounter rates in primary and selectively logged forest.

**Bibliography** Aleixo (2002), Andrade & Rubio (1994), Berlepsch & Leverkühn (1890), Borges *et al.* (2001), Canaday (1997), Clements & Shany (2001), Cory & Hellmayr (1925), Elliot (1890a), Gyldestoipe (1945a), Haffer (1997), Hellmayr (1903b, 1910), Hilty (2003a), Hilty & Brown (1986), Johns (1991), LeCroy & Sloss (2000), Menegaux & Hellmayr (1906a), Meyer de Schauensee (1950a, 1964), Meyer de Schauensee & Phelps (1978), Olivares (1964b), Parker *et al.* (1982), Peres & Whittaker (1991), Phelps & Phelps (1963), Pinto (1978), Ridgely & Tudor (1994), Schulenberg & Awbrey (1997a), Slater (1871), Sick (1993), Snethlage (1914), Stotz *et al.* (1996), Willis (1983d), Zimmer (1934d).

28. Chestnut-rumped Woodcreeper

*Xiphorhynchus pardalotus*

**French:** Grimpar flambé **German:** Beigekehl-Baumsteiger **Spanish:** Trepatroncos Silbador

**Taxonomy.** *Dendrocopus pardalotus* Vieillot, 1818. “Cayenne”.

Molecular data support placement as sister to *X. ocellatus*, to the exclusion of *X. chunchotambo*. Affinities with *X. spixii* and *X. elegans* have also been suggested. Two subspecies recognized.

**Subspecies and Distribution.**

*X. p. caurensis* Todd, 1948 - tepui region from S & SE Venezuela (Amazonas, Bolívar) and adjacent N Brazil E to W Guyana; possibly also W to extreme E Colombia.

*X. p. pardalotus* (Vieillot, 1818) - NE Amazonia, N of Amazon, in the Guianas and N Brazil (R Negro E to Amapá); purported records S of Amazon (lower R Tapajós) probably based on mislabelled specimens.

**Descriptive notes.** 21.5-23.5 cm; male 32-49 g, female 27-46 g. Medium-sized woodcreeper with slim, relatively long bill only slightly decurved. Nominative race has face and auriculars finely streaked deep buff and brown throughout, buff supercilium and eyering; crown and nape blackish-brown, crown with small, teardrop-shaped spots of deep buff that lengthen on nape; back and wing-coverts reddish-brown to olive-brown, entire back marked sparingly with elongate drop-like streaks with narrow blackish borders; rump, wings and tail rufous-chestnut, tips of outer primaries dusky; throat cinnamon-buff, feathers edged dusky,

narrowly in middle, more boldly along lower edge; olive-brown below, breast, sides and upper belly with blackish-edged cinnamon-buff streaks, these fading on belly and flanks, with lower belly and undertail-coverts more rufescent and with brownish mottling; underwing-coverts cinnamon-buff; iris dark brown; bill dark brown to black, lower mandible largely pale grey to pale brownish; legs and feet bluish-grey or grey, sometimes clear blue or blackish. Distinguished from *X. guttatus* by much smaller size, slimmer build, slimmer bill, streaking above and below narrower

and with bolder margins; from *X. ocellatus* and *X. elegans* by more richly coloured throat and streaking (cinnamon instead of buffy), breast more spotted and less streaked; *X. ocellatus* further differs by virtually unmarked back. Female is like male, but slightly smaller. Juvenile resembles adult, but bill shorter, streaks with weaker dark borders. Race *caurensis* has upperparts more rufescent, weaker streaking above and below, dark edges of streaks narrower. Voice. Song, given intermittently, most often at dusk and dawn, a series c. 2-5 seconds long of c. 15 notes, begins with 3-4 sharp "chip" notes but usually accelerates into rattle that fades at end, "chipl, chip, chip, chi-i-i-i-i-i-p" or "zut, zut, zut-zut-zut-t'l'l't'e'e e". Song and some calls similar in quality to call of *X. elegans* but lacking terminal whine. Alarm call a loud "peet, peet, peet"; other calls include squeaky, twittered "ik" that may be repeated, variable rattle of sharp "chip" notes, and a "long call" much like that of other dendrocolaptids, "che-e-e-e-e-ee-ee-pool-pool-ee-ee-e...".

**Habitat.** Primarily lowland evergreen forest, but also lower montane forest in tepui region. Occupies mostly tall *terra firme* forest, less often floodplain-forest; also wooded savanna in N of range. Principally in interior of mature forest, but regularly frequents older second growth, plantations, and forest edge. Mostly lowlands below 500 m; reaches lower subtropical zone to 1800 m on slopes of tepuis.

**Food and Feeding.** Chiefly insectivorous. Prey taken over ants often too small to identify, but larger items have included spiders, grasshoppers (Acrididae), cockroaches (Blattodea), beetles, ants, a large centipede (Chilopoda) and a large stick-insect (Phasmida); also attracted to emergences of winged ants, but few captures made. Stomach contents included beetles, crickets, hemipteran bugs, caterpillars, spiders, millipedes (Diplopoda), and a small scorpion. Core member, in pairs or, less often, individually, of mixed-species flocks of forest understorey, occasionally of those in canopy; marked preference for flocks led by *Thamnomanes* antshrikes, e.g. in Brazil present in 55% of such flocks in Roraima and 96-100% near Manaus, but in 0 and 27% of flocks lacking *Thamnomanes* at each respective site. In French Guiana prospected flocks for minimum of 521 days before settling to breed, with 2 ringed adults each switching flocks and settling 350-450 m from point of first capture; breeding birds apparently spend more time with flocks than do non-breeders. Forages while rapidly hitching up trunks and branches, primarily from understorey to subcanopy, sometimes into canopy; prey obtained mostly by gleaning from surface of trunks or limbs, or by peering and probing into bark crevices and knotholes, among vines and epiphytes, palm fronds, or clusters of live or dead leaves; sometimes pries or flakes off loose bark, or pecks on dead wood. Occasionally encountered away from flocks; a facultative ant-follower that sometimes forages in association with swarming army ants, then generally in pairs, but sometimes 3 or, rarely, 4 birds together. Over ants, most prey gleaned from trunks or nearby foliage, usually 0.5-5 m up but regularly to 10 m (occasionally 20 m or higher), while hitching up near-vertical trunks of small trees, less frequently larger ones; gleaning and pecking more frequent, but regularly sallies short distances (usually less than 1 m) to foliage, sometimes to ground, occasionally other substrates; apparently too restless to forage effectively over ants, and usually remains with them only short periods. Rather aggressive but, owing to its smaller size, supplanted or displaced at ant swarms by most other woodcreepers (e.g. *Dendrocincla merula*, *Nasica longirostris*, *Dendrocolaptes certhia* and *D. picumnus*, and *Hylexetastes perrotii*); regularly supplants or displaces only *Dendrocincla fuliginosa*; intraspecific disputes at swarms infrequent.

**Breeding.** In French Guiana, eggs in late Jul to mid-Sept, hatching at one nest on 22nd Sept and fledging at another on 26th Sept; in Manaus (Brazil), nest with single nestling in early to mid-Dec, and dependent young recorded mid-Oct to early Feb; apparently breeds during Sept-Jan dry season throughout range, but specimens in breeding condition early Oct to mid-Jun and in non-breeding condition Feb-Jun and late Oct to early Nov. Apparently requires c. 4-5 months to complete wing molt; a female was molting rectrices while incubating. May remain paired throughout year. Nest in natural cavity, often in rotting stump less than 5 m tall, entrance hole usually 2-4 m up and generally taller than wide (e.g. 9 × 3 cm and 8 × 3.5 cm), at one nest, cup 6 cm below entrance and egg placed atop bed of bark flakes. Clutch 1 egg, average 26 × 21 mm; nestling fed by both parents; fledgling stayed with parents for at least 3 months (near Manaus). In French Guiana, pairs raised average of 0-18 young per year, and estimated average annual survival 70%; success rate lower (10%) for nests observed near Manaus.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in lowland forest throughout range. Estimated densities in primary forest in French Guiana 7-12 pairs/100 ha. As most flocking and ant-following species, generally considered highly sensitive to loss and fragmentation of forest; abundance significantly decreased at sites in S Venezuela and French Guiana 5-12 years after selective logging (despite increase less than 1 year after harvest in one study, and only modest decrease after 1-2 years in the other). These findings suggest that slight increases in capture rates following isolation of 1-ha and 10-ha fragments near Manaus (Brazil), where birds foraged alone after flocks disbanded following fragmentation, may need to be examined over longer time period. Another study at Manaus revealed that even narrow forest roads may represent a barrier to flocks accompanied by this species, but that its frequency of occurrence in these flocks did not differ between forest interior and roadsides. An indicator of tropical lowland evergreen forest in N Amazonia.

## 29. Spix's Woodcreeper

### *Xiphorhynchus spixii*

**French:** Grimpard de Spix      **German:** Spixbaumsteiger      **Spanish:** Trepatroncos de Spix

**Taxonomy.** *Picolaptes Spixii* Lesson, 1830, no locality = Pará, Brazil.

Forms a superspecies with *X. elegans*, the two regarded as conspecific by some authors but treated as separate species in most accounts; recent analyses based on genetic and morphological data support recognition of two species, a monotypic *X. spixii* and a polytypic *X. elegans*. Races *juruanus* and *insignis*, regarded by most authors as races of *X. spixii*, and by some as full species, here recognized as races of *X. elegans*. Monotypic.

**Distribution.** SE Amazonian Brazil, S of Amazon, from R Tapajós and N bank of R Teles Pires E to N Maranhão (including Marajó I); purported record from Ceará (NE Brazil) involved a misidentified subadult *X. picus*.

**Descriptive notes.** 18.5-21 cm; 27-36 g. Medium-sized woodcreeper with moderately long, slim bill only slightly decurved. Has dusky brown face finely streaked buff; pale supercilium and eyering;

and undertail-coverts largely unmarked; underwing-coverts deep ochraceous; iris dark brown; bill dark brown, paler tip; legs and feet bluish to grey. Differs from *X. elegans* in more heavily streaked back, unmarked wing-coverts, duller coloration at bend of wing, streaked rather than spotted breast and belly; plumage patterns similar to sympatric races of *X. guttatus*, but size much smaller, bill slimmer, and markings more deeply buff; distinguished from *X. obsolitus* by largely dark bill, habitat, vocalizations. Sexes similar. Juvenile resembles adult, but margins of streaks below poorly defined. Voice. Song a rapid and slightly descending trill ending in terminal whine, 30 notes in 3-3.5 seconds, "twe-tee-ti-ti-ti...-ti-ti-it, wheu", similar to song of *X. elegans* but somewhat faster. Calls also quite similar, possibly given somewhat more rapidly.

**Habitat.** Chiefly evergreen forest, mainly *terra firme* forest, but ranging into *várzea* forest at some sites. Primarily interior of mature forest, less often second growth, only occasionally visiting forest edge. Roosts alone in cavities like those used for nesting; one roost 2 m up, near top of rotten palm stump covered with mosses and epiphytes. Amazonian lowlands below 500 m.

**Food and Feeding.** Largely insectivorous; various orthopterans, including a large grasshopper (Acrididae), observed being taken over ant swarms. Stomach contents included beetles, spiders, ants, pentatomid and other hemipteran bugs, flies and fly larvae, and caterpillars. Most prey quite small, but one stomach contained caterpillars up to 50 mm in length. Single birds (less frequently pairs) are regular associates of mixed-species understorey flocks, but sometimes encountered alone or in association with army ants (principally *Eciton burchelli*). Forages while rapidly hitching up trunks and branches, primarily in lower and middle levels of forest; prey apparently obtained largely by pecking at surface of trunks or limbs, or by briefly peering and probing into bark crevices, rotten limbs, epiphyte roots, vine tangles, palm fronds, or clusters of living or dead leaves; less frequently pries up loose bark strips to expose hidden prey. Foraging manoeuvres similar to those of *X. guttatus*, but moves rapidly, instead of deliberately searching for prey. Seems to be an indirect follower of army ants, attracted more to accompanying birds than to the ants and the prey they flush; usually singly, sometimes 2 (very rarely 3), at swarms, where seen to forage within 5 m of ground (occasionally to 10-15 m), by hitching up slim, vertical trunks 5-25 cm in diameter. Attempts to capture prey over ants involve sallies to foliage, less frequently to the ground or air, but more often pecking from trunks, foliage or vines; also observed to dig into rotten trunks. Suggested as foraging too actively for efficient exploitation of slow-moving ants, which it usually follows for only short periods. Rather aggressive towards conspecific and other woodcreepers; seen to supplant *Dendrocincla fuliginosa* and even attack larger *Dendrocolaptes certhia*, but usually supplanted by latter species and by *X. guttatus*, *Dendrocincla merula* and *D. fuliginosa*; also seen supplanted by both Olive-backed Foliage-gleaner (*Automolus infuscatus*) and Black-spotted Bare-eye (*Phlegopsis nigromaculata*).

**Breeding.** Poorly known. Specimens in breeding condition in late Nov to late Feb (Marajó I), and nests with eggs in mid-Dec to early Mar; moulting remiges in late May and completing moult in early Jul near Belém. Nest in cavity, one in dead branch of *Inga* tree, another 1 m above ground in dead stump, both lined with bark chips and wood dust. Clutch 2 white eggs.

**Movements.** Presumably resident; some individually marked birds remained within relatively small area for up to 2-5 years.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in lowland forest throughout limited range. Believed to be highly sensitive to loss and fragmentation of forest. An indicator of tropical lowland evergreen forest in S Amazonia.

**Bibliography.** Aleixo (2002), Elliot (1890b), Gyldestolpe (1951), Halfer (1997), Hellmayr (1905), Meyer de Schauensee (1966), Novaes (1969), Oniki (1970, 1971b, 1972a, 1974), Oren & Henriques (1994), Pinto (1953, 1978), Ridgely & Tudor (1994), Ridgway (1888b), Schubart *et al.* (1965), Sick (1993), da Silva *et al.* (1990), Sneathlage (1914, 1935), Stotz *et al.* (1996), Teixeira, Otch *et al.* (1993), Willis (1983d).

## 30. Elegant Woodcreeper

### *Xiphorhynchus elegans*

**French:** Grimpard élégant      **German:** Schmuckbaumsteiger      **Spanish:** Trepatroncos Elegante  
**Other common names:** Hellmayr's Woodcreeper (*insignis*); Ihering's Woodcreeper (*juruanus*); Ornate Woodcreeper (*ornatus*, *buenavistae*)

**Taxonomy.** *Dendroornis elegans* Pelzel, 1868, Engenho do Gama, Mato Grosso, Brazil.

Forms a superspecies with *X. spixii*; regarded as conspecific by some authors, but recent genetic and morphological data support recognition as a full species. Races *insignis* and *juruanus* regarded by most authors as races of *X. spixii* or by some as a full species; however, genetic evidence supports treatment of *juruanus* at least as a subspecies of *X. elegans*. Race *buenavistae* poorly differentiated from *ornatus*, and *juruanus* poorly differentiated from *insignis*, but remaining taxa inhabit large regions of Amazonia, show little or no clinal variation and intergrade along narrow zones of contact. Plumage variation further shows a "leap-frog" pattern, with similarly appearing *ornatus* and nominate separated geographically by phenotypically different *juruanus*. Five subspecies recognized.

**Subspecies and Distribution.**

*X. e. buenavistae* J. T. Zimmer, 1948 - E slope of E Andes in SC Colombia (upper R Orinoco drainage in W Meta and Caquetá); unverified (but widely cited) report from upper Magdalena Valley (Huila).

*X. e. ornatus* J. T. Zimmer, 1934 - NW Amazonia, N of Amazon, in SE Colombia (E Vaupés, S Amazonas), E Ecuador and NE Peru (N of R Marañón), and immediately adjacent NW Brazil (E to R Iça, possibly farther; specimens allegedly from São Paulo de Olivença, S of Amazon, probably originate from adjacent N bank or a nearby river island).

*X. e. insignis* (Hellmayr, 1905) - Andean foothills of EC Peru (S of R Marañón, W of R Ucayali); intergrades with *juruanus* in valley of R Ucayali.

*X. e. juruanus* (H. von Ihering, 1905) - SW Amazonia, S of Amazon, in E & SE Peru (E of R Ucayali), W Brazil (E to R Purús and upper R Madeira, S to Acre) and NW Bolivia (Pando, Beni, La Paz); populations between R Purús and R Madeira intermediate with nominate.

*X. elegans* (Pelzeln, 1868) - S Amazonia, S of Amazon, in Brazil (R Madeira E to R Tapajós and S bank of R Teles Pires, S to SW Mato Grosso) and adjacent E Bolivia (extreme NE Santa Cruz).

**Descriptive notes.** 18-22.5 cm; male 31-38 g, female 29-35 g (nominate). Medium-sized woodcreeper with relatively long, slim, nearly straight bill. Nominata race has blackish-brown face boldly streaked buff, weak supercilium, whitish lores; crown and nape dark olive-brown with small blackish-edged buff spots, these becoming more elongate on nape; back and scapulars somewhat paler brown, marked throughout with large teardrop-shaped buff spots having conspicuous blackish margins; rump, wings and tail cinnamon-rufous to rufous-chestnut, lesser and median coverts, less frequently also greater coverts, with buff shaft

stripes or subterminal spots, primary tips blackish, bend of wing cinnamon-rufous; throat buff whitish, lower edge with dusky feather margins producing scaly appearance; underparts greyish olive-brown, becoming somewhat more ochraceous on lower belly, breast and sides with relatively large, teardrop-shaped spots or chevrons that are buff with blackish edges, these fading by lower breast, leaving belly, flanks and undertail-coverts weakly streaked to largely unmarked; iris light chestnut to dark brown; upper mandible dark brown to black, lower mandible grey to dirty bluish-grey with brownish tip; legs and feet dark grey, greenish-grey or bluish olive-grey. Much smaller and weaker-billed than any race of *X. guttatus*. Race *juruanus* similar to sympatric races of *X. chunchotambo* but spots on breast smaller, throat somewhat paler, vocalizations different and, in SE Peru and N Bolivia, bill longer, darker; other races differ from *X. ocellatus* in having back more extensively and more conspicuously marked. Differs from *X. spixii* in having rounded spots rather than streaks on back, spotted wing-coverts, more rufescent bend of wing, and underparts with rounded spots (rather than elongate streaks) that are largely restricted to breast. Female is slightly smaller than male. Juvenile resembles adult but darker, with fine shaft streaks on scapulars and wing-coverts. Race *ornatus* is closest to nominate, but spots both above and below larger, coloration at bend of wing duller, general coloration warmer, and rump, wings and tail deeper rufous; *huenavistae* is also most similar to nominate but bill much paler, shoulder less rufous, streaking on scapulars and coverts less conspicuous; it is apparently greyer than *ornatus*, with spotting above and below smaller and less ochraceous. Races *insignis* and *juruanus* both differ from nominate in having unmarked wing-coverts, markings above narrower, more elongate, largely restricted to upper back; *insignis* has spots above deeper and more ochraceous in colour, bill more strongly decurved and grey, becoming blackish at base and whitish distally; race *juruanus* is most like *insignis*, but bill similar to nominate in shape and colour, spots below significantly smaller and largely confined to upper breast, size slightly larger than others. **VOICE.** Song, given primarily at dawn and dusk, 4-5-5 seconds long, a descending series of c. 30 ringing whistles that begins softly and slows at end, "whit, whit, wit, wit, wit, wit, wee, wee, wit, wit, wit, wit, wit, wew"; also distinctive series 3-4 seconds long of 10-20 sharp whistles that begins with 1-2 forceful notes, then descends and slows, before ending in terminal whine, "chip, chip, cher-cher-che-che-che-che-che-che-che, weeur", and extended series of "eek" notes that slide up and down in frequency and vary in quality from musical to harsh; song appears not to vary much geographically. Most common call an explosive series of 2 (sometimes more) sharp "chip" notes followed by whine, "chip, chip, eerh"; calls very like those of *X. spixii*, but possibly given more slowly.

**Habitat.** Chiefly humid evergreen forest, principally *terra firme* and on floodplains, occasionally also seasonally flooded forests (both *várzea* and *igapó*) and even forested river islands; along S fringe of Amazonia continues a short way into Cerrado region, frequenting gallery forest and woodlands on sandy soils; may extend into montane evergreen forest at upper end of elevational range. Prefers interior of mature forest, but occasionally occurs in second growth, in thickets of *Guadua* bamboo, or at forest edge. Mostly in Amazonian lowlands below 600 m, but ranges up E Andean slopes into subtropical zone locally to 1500 m.

**Food and Feeding.** Diet chiefly arthropods, but small vertebrates occasionally taken. Stomach contents primarily beetles and orthopterans of various types, each representing 25-30% of total, with lesser quantities of spiders, ants, larvae, bugs, and a few small vertebrates; in relation to prey availability, seems to prefer orthopterans and larvae, while avoiding cockroaches (Blattodea). Over ants, also seen to take a large scorpion, which was pounded and chewed before being swallowed. Most prey relatively small, generally less than 1 cm, often much smaller, but largest items 4 cm in length. Single birds, less frequently pairs, are core members of mixed-species flocks of forest understorey. In study in SE Peru individually marked birds spent most of time with flocks (average 83%), but also switched among two adjacent flocks within the territory (about twice as much time spent in primary flock as in secondary flock); seems to show marked preference for flocks with *Thamnomanes* antshrikes over those without, and in SE Peru seems to prefer flocks led by Dusky-throated Antshrike (*T. ardesiacus*) to those led by Bluish-slate Antshrike (*T. schistogynus*), possibly because these flocks forage in lower strata. Found with flocks that move through forest at c. 20 m in 10 minutes, significantly more slowly than those frequented by *X. chunchotambo*; however, this appears to reflect preference to join flocks moving at that rate, rather than the species itself setting rate of movement. Forages primarily while rapidly hitching up trunks and branches from understorey to subcanopy, most often at 2-10 m, less frequently to 15-20 m above ground. Most prey gleaned or pecked from surface of trunks or limbs (40-75% in various studies); items also taken by probing into epiphytic mosses and lichens (20%), vine stems (15%), dead leaves (10-15%), and occasionally from live foliage (10%) or other substrates; sometimes pries off strips of loose bark. Encountered relatively infrequently at army-ant swarms, then usually in pairs (sometimes alone), foraging primarily within 4 m of ground (most often below 1 m), occasionally to 15 m; even when with ants, most prey pecked from trunks, with some items gleaned from nearby leaves or taken in sallies to the ground or trunks, occasionally during mid-air sallies after falling prey. Suggested as being too active to forage efficiently in association with army ants, and usually does not follow them for long periods; probably an "indirect" ant-follower, attracted more by other birds than by the ants and the prey they flush. Relatively aggressive, begins fights not only with subordinate species but also at times with larger ones; seen to be supplanted by *Dendrocolaptes hoffmanni* and *D. certhia*, and by *X. guttatus*, but supplants other small *Xiphorhynchus* and *Dendrocincla fuliginosa*; aggressive interactions with conspecifics not uncommon. High degree of overlap in diet and substrate use with both *X. chunchotambo* and *X. obsoletus* results in intolerance (i.e. aggression at almost every encounter when among flocks), also in interspecific territoriality producing checkerboard pattern of distribution among flocks in SE Peru; reciprocal turnover of territories with *X. chunchotambo* documented. Pair defends territories of two mixed-species flocks, and largely disregards intruders away from immediate area of these flocks. Territories did not appear to expand or change in location once established; with all new territories established by individuals previously unknown at site. Birds were never displaced from primary flock, and only rarely displaced from secondary flock, during interactions with *X. chunchotambo*.

**Breeding.** Specimens in breeding condition in mid-Aug to mid-Oct in Brazil (N Mato Grosso); adult incubating in late Sept, eggs hatching in early Oct and a chick fledging in late Oct at a nest in SE Peru. Nest in tree cavity; only one nest described in detail, c. 65 cm above ground in dead stump 1.5 m tall, with covered top, elongate side entrance 18 x 3 cm, no nest material visible at bottom of cavity. Clutch 2 white eggs; incubation period at least 16 days; hatchling with short yellow bill, fluffy grey down, eyes open and feather sheaths appear on back and wings at c. 1 week, feathers on head 4 days later; nestling period 18-19 days, but one chick disappeared from nest at c. 10 days of age. In SE Peru, one individual was at least 8 years old at end of study, occupied same territory for 7 of those years; three others at site were at least 6 years old.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in lowland forest throughout core of range in Brazil, Peru, and even N Bolivia; rare to uncommon and quite local in lowlands of E Ecuador and possibly SE Colombia. Estimated density in mature floodplain-forest in SE Peru 4-6 pairs/100 ha of occupied habitat, where home ranges 4-5-10 ha (average 7 ha), significantly smaller than those of *X. chunchotambo* at same time. Dependent on forest, and thus believed to be highly sensitive to loss and fragmentation of this habitat. An indicator of tropical lowland evergreen forest in S Amazonia, and more specifically of *terra firme* forest and floodplain-forest in SE Peru.

## 31. Striped Woodcreeper

### *Xiphorhynchus obsoletus*

**French:** Grimpard strié

**German:** Streifenbaumsteiger

**Spanish:** Trepatorncos Loco

**Taxonomy.** *Dendrocolaptes obsoletus* M. H. K. Lichtenstein, 1820, no locality = state of Pará, Brazil.

Relationships uncertain; on basis of molecular data, apparently ancestral to a morphologically variable clade that includes *X. guttatus*, *X. susurrans*, *X. flavigaster* and *X. lachrymosus*, possibly also *X. erythropygius* and *X. triangularis*. Assessment of race *notatus* complicated by marked individual variation in coloration, and intergradation over seemingly wide area with both nominate and *palliatius*; birds from R Purús drainage (possibly also R Madeira), in W Brazil, sometimes recognized as race *multiguttatus*, but intermediate between nominate and *palliatius*. Validity of poorly differentiated race *caicarae* (relative to nominate), with biogeographically unlikely range, is uncertain. Four subspecies recognized.

**Subspecies and Distribution.**

*X. o. notatus* (Eyton, 1852) - drainages of R Apure, upper R Orinoco, lower R Caura and upper R Negro in E Colombia, W & S Venezuela and adjacent NW Brazil; birds from lower R Negro intermediate with nominate.

*X. o. caicarae* J. T. Zimmer & Phelps, Sr., 1955 - middle Orinoco Valley in C Venezuela (NW Bolívar). *X. o. palliatius* (Des Murs, 1855) - W Amazonia, both N & S of Amazon, in SE Colombia (Meta, Caquetá), E Ecuador, E Peru, W Amazonian Brazil (E to R Negro and to R Jurua) and N Bolivia (S to N La Paz and NW Beni); birds from R Purús intermediate with nominate.

*X. o. obsoletus* (M. H. K. Lichtenstein, 1820) - E Amazonia, in E Venezuela (Delta Amacuro), the Guianas and N Brazil (lower R Negro E to Amapá and, S of Amazon, from R Madeira E to R Tocantins and S to W & N Mato Grosso); populations in NE Bolivia (NE Santa Cruz) and NE Venezuela (E Monagas) likely represent this race.

**Descriptive notes.** 18-20.5 cm; male 27-37 g, female 24-36 g. Medium-sized woodcreeper with slim, slightly decurved bill and about as long as width of head. Nominata race has face finely but evenly streaked creamy buff and dark brown, becoming bold scaling on side of neck, pale supercilium indistinct or lacking; crown and nape blackish to dark olive-brown, extensively marked with teardrop-shaped whitish-buff spots with dusky margins, back olive-brown (sometimes slight rufous tone), almost throughout with elongate dusky-margined whitish-buff streaks, rump, wings and tail cinnamon-rufous to rufous-chestnut, lesser coverts olive with fine

shaft streaks, primary tips dusky to dark brown; throat buff white, often with weak scaling; underparts greyish olive-brown (sometimes more rufescent) with black-edged streaks of buffy-white extending boldly across breast and upper belly, before narrowing and weakening on lower belly and undertail-coverts; underwing-coverts cinnamon; iris brown to dark brown; upper mandible pale brownish to greyish-brown, base and culmen darker, cutting edges ivory-coloured, lower mandible pale bluish-grey to light brown; legs and feet slate-grey, blue-grey, greenish-grey or dark brown. Similar to *X. picus* but bill duskier and slightly decurved, overall coloration more olive, back and underparts more extensively streaked, latter also with streaks more linear and usually with blackish edges; *X. pargalotus* has bill black, throat and streaks more cinnamon in colour, and is largely restricted to *terra firme* forest. Female is slightly smaller than male. Juvenile resembles adult, but margins of streaks and spots on nape, back and underparts more poorly defined. Races differ mainly in general coloration, but with substantial individual variation both above and below: *notatus* is more rufescent than nominate, with throat and streaks (both above and below) deeper buff to ochraceous; also more finely and more narrowly streaked than *palliatius*; *palliatius* even more rufescent overall, with markings more deeply coloured, less contrast between back and rump, and bill heavier; *caicarae* is on average smaller than nominate, with underparts browner, less greyish, bill shorter. **VOICE.** Song, among first heard in flooded forests at dawn and last heard at dusk (also intermittently during day), a trill 1.5-3 seconds long, 20-35 sharp notes, first stuttering, then speeding up slightly, rises conspicuously at end, "che-e-e-e-e-e-e-e-e-e-e-ick!"; at some sites in E Colombia, song said to be instead a sharp "peep" followed by trill; similar but slightly descending trill sometimes given when agitated. Calls include "sip" note like that of hummingbird (Trochilidae), also "ti-dik" and dry twittering "tit-it-it" or "si-si-sip".

**Food and Feeding.** Diet chiefly arthropods, occasionally small vertebrates. Stomach contents included various beetles, ants, grasshoppers (Acrididae), spiders, scorpions, bugs, cicadas, cockroaches (Blattodea), caterpillars, centipedes (Chilopoda), millipedes (Diplopoda), a small crab, and either small frogs or lizards. Most prey relatively small (less than 15 mm), especially for the bird's size, but items over 20 mm in length and sometimes to 60 mm regularly taken. In relation to prey available in clusters of dead leaves, selects for various orthopterans but avoids cockroaches and, to lesser degree, spiders. Overlap in diet high with smaller *X. elegans* and *Dendrocincla fuliginosa*, less so with *D. merula*. Forages singly, occasionally in pairs; rarely 3 together at ant

swarms. Regular associate of mixed-species flocks frequenting mid-levels and subcanopy, sometimes those in understorey or even canopy. Radio-tracked birds at site in SE Peru spent 16% of time with flocks, accompanying them in transitory fashion; present in 26% of flocks observed in E Amazonia, 18–21% in S Amazonia, 39% in SW Amazonia, and 16–65% in E Brazil. One study documented marked preference for flocks led by *Thamnomanes antshrikes* in E Brazil but not in S Amazonia; strong association with Spot-winged Antshrike (*Pygiptila stellaris*) found in another study. Regularly follows ant swarms (*Eciton burchelli*, sometimes *Labidus praedator*) but, unlike “professional” ant-followers, does not investigate bivouacs. Forages while hitching up trunks and branches, primarily from mid-levels to subcanopy, sometimes higher and often lower, especially when over ants; mean foraging height in one study 11 m, with range 1–21 m. Most prey taken either from surface of trunks or limbs by gleaning or pecking (10–45% depending on study), or from clusters of suspended dead leaves or palm fronds by probing (35–63%); occasionally searches epiphytes, vine stems, live foliage or other substrates; sometimes pries off bark flakes, manipulates or thrashes substrate with bill, or pecks on dead wood or termite (Isoptera) nests to expose prey from interior. Routinely searches larger leaves than do other dead-leaf specialists, and regularly hangs from palm fronds or clings to large *Cecropia* leaves. When over ants, uses medium-sized trunks (mostly 5–20 cm diameter), typically vertical ones, but sometimes uses angled or even horizontal perches; at some sites forages mostly 2–10 m up (occasionally higher or lower), above zone of high competition near ground, but at others forages extensively within 1 m of ground; pre-capture techniques when associated with ants mostly similar to those used away from them, but also makes regular sallies to take items on ground or nearby foliage, sometimes in mid-air. Quite aggressive, beginning fights not only with smaller species but also with larger ones; aggressive interactions with conspecifics not uncommon. Constantly supplanted only by much larger *Hylexetastes perrotti*; occasionally seen to initiate fights with, and sometimes supplant, larger *Dendrocolaptes* (*D. picumsum*, *D. hoffmannsi*, *D. platyrostris*, *D. certhia*) and *X. promeropirhynchus*, but clearly dominant over smaller *Dendrocincla fuliginosa*, less so over *D. merula*, congeners and *Lepidocolaptes albolineatus*. Also aggressive towards non-woodcreepers, sometimes displacing various antbirds (Thamnomphiliidae), picids such as Yellow-tufted Woodpecker (*Melanerpes cruentatus*) and Chestnut Woodpecker (*Celeus elegans*), Grey-headed Tanager (*Eucometis penicillata*) and, especially, foliage-gleaners of genera *Philydor* and *Hylocistis* (Furnariidae). Overlap in diet (high) and substrate use (moderate) with *X. promeropirhynchus*, *X. chunchotambo*, *X. picus* and *L. albolineatus*, resulting in partial tolerance (i.e. fights when encountered among flocks on occasion, but often foraging in close proximity).

**Breeding.** Breeds during main dry season in French Guiana, in Mar in Guyana, and eggs in Jul in Surinam; birds in breeding condition in Jan–May in S Venezuela, N Brazil and the Guianas, in Feb in S Amazonia and in early Oct in N Bolivia; adults with dependent young in mid-May in E Amazonia and mid-Sept to early Dec in French Guiana, and juveniles in mid-Oct to early Feb in S & SW Amazonia and mid-May in E Amazonia. Nest usually low in natural cavity in dead tree or in old woodpecker (Picidae) hole; one nest was 7–8 m above ground. Clutch 1–3 white eggs, usually 2, apparently 27–22 mm (some published measurements believed too small for this species, more likely pertain to *X. picus*). Adults sometimes seen with a dependent juvenile at ant swarms.

**Movements.** Apparently resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common in lowland forests in most of range. At site in SE Peru, densities highest in mid-successional vegetation (27.5 pairs/100 ha), slightly lower in late-successional growth (22.5 pairs/100 ha), and lower still in mature floodplain-forest (9–21 pairs/100 ha of occupied habitat); home ranges in mature floodplain-forest at site averaged 6 ha. More abundant than smaller members of genus in SE Peru, apparently reflecting use of richer foraging substrates and possibly its ability to repel smaller species from these substrates. Largely dependent on intact but not necessarily undisturbed forest, with most populations inhabiting a region with much forest remaining and probably only moderately sensitive to disturbance; nominate race, however, largely restricted to scattered fragments of lowland Atlantic Forest, and likely to be moderately to highly sensitive to continued loss of forest.

### 33. Cocoa Woodcreeper

#### *Xiphorhynchus susurrans*

**French:** Grimpai cacao

**German:** Kleiner Fahlkehl-Baumsteiger

**Spanish:** Trepatroncos Cacao

**Other common names:** Lawrence’s Woodcreeper (“*namus* group”)

**Taxonomy.** *Dendrocolaptes susurrans* Jardine, 1847, Tobago.

Sister to *X. guttatus* and treated by most authors as conspecific, but recently elevated to full species on grounds of differences in calls and body size; geographical patterns in songs, however, more complex than previously realized, and size differences do not correspond to species limits as presently recognized. No published data support recognition by most recent authors of “*namus* group” with *X. susurrans* instead of *X. guttatus*. Two subspecies groups, differing markedly in plumage patterns: “*susurrans* group” (with *jardinei* and *margaritae*) in E of range (Trinidad, Tobago, Margarita I. and adjacent Venezuelan mainland), and “*namus* group” (including all remaining races) in Central America, N Colombia and N & W Venezuela. Preliminary molecular analyses suggest close affinity of “*namus* group” to nominate *X. guttatus* and allied race *polystictus*, but populations in “*susurrans* group” were not included in the analyses. Birds from NE Colombia and adjacent NW Venezuela, described as race *demonstratus*, considered inseparable from *namus*. Eight subspecies recognized.

#### **Subspecies and Distribution**

*X. s. confinis* (Bangs, 1903) - Caribbean slope of E Guatemala and N Honduras.

*X. s. costaricensis* (Ridgway, 1888) - Central America, on both slopes, from St. Honduras to W Panama (W Chiriquí, W Bocas del Toro).

*X. s. marginatus* Griscom, 1927 - Pacific slope of C Panama (E Chiriquí, Veraguas and W Azuero Peninsula).

*X. s. namus* (Lawrence, 1863) - both Caribbean and Pacific slopes of E Panama (W to Canal Zone and E slope of Azuero Peninsula), N Colombia (E to W Guajira, Atrato Valley, lower Cauca Valley, upper Magdalena Valley S to Tolima, and E of Andes in NW Arauca) and W & N Venezuela (Zulia, Táchira and W Apure E to E Miranda).

*X. s. rosenbergi* Bangs, 1910 - upper Cauca Valley in Valle (W Colombia).

*X. s. jardinei* (Dalmás, 1900) - NE Venezuela (NE Anzoátegui, N Monagas, Sucre).

*X. s. margaritae* Phelps, Sr. & Phelps, Jr., 1949 - Margarita I. off N Venezuela.

*X. s. susurrans* (Jardine, 1847) - Trinidad and Tobago; also one record from adjacent NE Venezuela (SE Sucre).

**Descriptive notes.** 22.5–25.5 cm, male 43–57.5 g, female 41.5–48 g (“*susurrans* group”); 18.5–24.5 cm, 35–58 g (“*namus* group”). Medium-sized woodcreeper with long, relatively heavy bill slightly decurved and prominently hooked at tip. Nominative race has dusky lores and auriculars, the latter with buffy streaks, dusky-bordered whitish supercilium; crown and nape dark brown to blackish, feathers with elongate buff spot, becoming streaks on neck and nape; upper back and wing-coverts olive-brown to brown, with blackish-edged buff elongate spots on upper back, narrowing to streaks on middle of back and disappearing altogether on

lower back; lower back, rump, remiges and tail rufous-chestnut, primaries with dusky tips; throat whitish to pale buff with narrow blackish scaling; underparts greyish-olive to buffy brown, upper breast with dusky-edged spots of buffy-white, becoming elongate on lower breast and fading by belly and undertail-coverts, which are weakly barred to largely unmarked; underwing-coverts cinnamon; iris dark brown; bill black, base of lower mandible pale greyish to horn; legs and feet dark blue-grey, greenish-grey or slaty. Most likely confused with *Lepidocolaptes souleyetii*, which is more likely to be found in open habitats, and is much smaller with bill slimmer, more decurved and extensively pale. Members of “*susurrans* group” distinguished from both “*namus* group” and *X. guttatus* by whiter throat and spotted instead of streaked pattern on breast. Members of “*namus* group” distinguished from geographically nearest populations of *X. guttatus* (race *polystictus*) by smaller size, throat mostly unmarked and more richly buff, plumage more olive. Female resembles male, but smaller. Juvenile of “*namus* group” is darker than adult, throat faintly scaled dusky, crown less spotted, streaks below broader and often tending towards bars, bill shorter and blacker. Race *jardinei* similar to nominate, but throat and underparts deeper buff, back more rufescent; *margaritae* slightly smaller than both *susurrans* and *jardinei*, lacks scaly pattern on throat, has fewer and larger spots on throat and breast; members of “*namus* group” are less similar to “*susurrans* group” of present species than to *X. guttatus* because underparts broadly streaked rather than spotted; *costaricensis* is similar to *namus*, but back and rump darker and more deeply reddish, darker and more olive below, streaking both above and below somewhat reduced; *confinis* similar to *costaricensis* and *namus*, but throat paler and more whitish (less buffy), breast streaks weaker but extending farther down belly; *marginatus* also like *costaricensis* but has wings and tail darker chestnut, sooty tips of primaries darker and more extensive, throat brighter buff, edges of crown and nape feathers more blackish; *rosenbergi* is most like *namus* but has streaks on breast wider and much more boldly edged black. **VOICE.** Remarkably vocal for a woodcreeper often singing incessantly in early morning and late afternoon (sometimes for much of day when breeding) from concealed perch high in canopy. Song, a loud series of 7–20 clear but upward-inflected whistles (each described as “doy”, “wick” or “weet”), given at 3 notes per second, either on same pitch or beginning fast and rising slightly, before fading and descending, e.g. “ki, ki, kuee, kuee, whe, whe, whe, whe, whe, whe”. Long call, given intermittently throughout day by both sexes, a loud descending series that gradually loses intensity, e.g. “peer, peer, peer, peert”, “she-you, she-you, cherp chew” or “che-e-e-r, che-e-e-r, che-e-e-r”; short call, given most frequently when going to roost or when incubating (but not when feeding young), a sharp, piercing whistle described as “peepeer” or “pyewl”; similar but drier “chu” or “choe” may be given in alarm; calls generally similar to those of *X. guttatus*. Many adult calls given by fledglings, but with less volume.

**Habitat.** Chiefly humid evergreen forest of lowlands, occasionally into adjacent foothills. Principally gallery forest, deciduous woodland, older second growth, and forest edge; sometimes interior of mature forest, or outside forest in younger second growth, plantations, or clearings with scattered trees. Some coastal populations inhabit mangroves, and occupies arid scrub on Margarita I. Primarily lowlands below 900 m, but ranges in small numbers into subtropical zone in foothills; to 1350 m in NW Colombia and 2400 m in N Venezuela. Occurs syntopically with *X. flaviventer* in Caribbean lowlands of Honduras. Roosts alone in tree cavities, natural one apparently preferred over old woodpecker (Picidae) hole; one documented roost 1 m above ground, another at 4.5 m up; leaves roost at first light, returns in near darkness.

**Food and Feeding.** Diet chiefly arthropods, but occasionally takes small vertebrates. Prey observed taken or found in stomachs includes beetles, cockroaches (Blattodea), grasshoppers (Acrididae), crickets (Gryllidae), caterpillars and other insect larvae, cicadas (Cicadidae), spiders and their egg sacs, earwigs (Dermaptera), moths, scorpions, spiders, centipedes (Chilopoda), small isopods, also occasionally frogs and small lizards. Prey often of moderate size, with many items 1–1.5 times length of bill (smaller prey often not identified). Most often forages alone (occasionally 2 individuals together), but sometimes with mixed-species flocks or in association with swarms of army ants (*Eciton burchelli*, occasionally *Labidus praedator*, once *E. hamatum*). In one study in SW Costa Rica, present at 21% of ant swarms monitored; most swarms attended by single bird, sometimes 2, very rarely 3 together. Occasionally checks inactive bivouacs and approaches play-back of calls of Bicoloured Antbird (*Gymnophaps leucaspis*), both types of behaviour typical of “professional” ant-followers. Forages intently while hitching up trunks and branches, often in spiral motion, from understorey to canopy (mostly mid-levels and subcanopy when away from ants); unlike some congeners, seems to prefer uppersides of limbs to undersides. Most prey either gleaned from crevices or under bark of trunks or branches, or taken by probing into or rummaging among dead leaves, epiphytes, clumps of moss, or knot-holes; sometimes pecks with open bill at rotting wood or flakes bark to expose hidden prey, and has been observed at dawn to take moths attracted by lights left on at night. Over ants, descends trunks to undergrowth, mostly below 2 m, infrequently above 5 m, regularly dropping to ground to take flushed prey, but forages higher in presence of competing antbirds; in Panama uses slim to medium-sized trunks (mostly 5–50 cm diameter), favouring near-vertical perches, but uses uppersides of limbs more often than undersides; in Trinidad, where fewer competing antbirds, even slimmer and often angled or even horizontal perches used, and most prey taken from ground. Over ants, food captured both by gleaning and by short sallies to ground or foliage. Relatively aggressive, especially when attending army ants; usually supplanted by larger *X. lachrymosus* and *Dendrocolaptes sanctithomae* (occasionally supplants

both), but persistently supplants the smaller *Dendrocincla fuliginosa*. Similar encounters with non-woodcreepers include instances of being supplanted by aggressive thamnophilids (*Phaenostictus mcleannani* and *Gymnophaps leucaspis*), and supplanting smaller Spotted Antbird (*Hylophylax naevioides*), Grey-headed Tanager (*Eucometis penicillata*), and Swainson's and Grey-cheeked Thrushes (*Catharus ustulatus* and *C. minimus*). Also quite aggressive toward conspecifics.

**Breeding.** Breeds in Apr-Jun in N Venezuela and Mar-Aug in Trinidad and Tobago; nests with eggs in Mar-Jul in Costa Rica and Panama, early Apr to late Jun in Trinidad; elsewhere, birds in breeding condition in Jan-May in N Colombia and early Jul-early Aug in Nicaragua; juveniles in Apr in Trinidad, in late May in Panama and in early Jul in Nicaragua. Nest in existing cavity, including hollow trunk, dead stump, large bamboo stalk, gap between roots of strangler fig, cavity in building, and even within partly covered box, natural cavity seemingly preferred, 1-6.5 m up but often near ground (often below 2.5 m), entrance usually an elongate slit and can be quite large in diameter; may enlarge entrance or otherwise modify existing cavity; lined (probably by female only) with bits of bark and wood, or with weed stems, dead leaves, foliose lichens or plant down, deeper cavities sometimes filled with many fragments of bark and wood (18 cm deep in one nest), but chamber still can be as much as 1 m below entrance. Clutch 2 white eggs, average 30 × 22.5 mm in Trinidad, 28.5 × 19.5 mm in Costa Rica; limited data suggest that pair bonds are brief and that young raised by single parent, presumably female; incubation in long sessions, at various nests averaging 42-145 minutes (range 18-181 minutes), with much shorter recesses (average 21-38 minutes, range 3-48 minutes); one bird was in attendance for 80% of active period during an entire day at one observed nest, another for 70% during morning hours; incubating bird regularly returns with bark flake or flakes; incubation period 18 days; hatchling has eyes closed and dark grey down c. 2 cm long, pin-feathers erupt on dorsum at 1 week, body and wings largely feathered (head mostly naked, rectrices mostly ensheathed) at 17 days; nestlings brooded 25-30% of time when less than 4 days old, progressively less with age, until not brooded at all after 9-10 days; nestlings fed chiefly with insects, sometimes spiders or small *Anolis* lizards, always brought one at a time in

parent's bill, at an hourly rate of 0.5 meals for each 2-day old nestling, increasing to 1 meal when young 1-2 weeks old, larger young also receive larger meals; nestling period 19-20 days; young do not return to nest after fledging. Annual adult survival estimated at 76% at sites in Trinidad and 67% in Panama.

**Movements.** Apparently resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout most of extensive range, including Trinidad and Tobago; uncommon to rare and local at upper end of elevational range, in semi-arid NW Costa Rica, and in N portion of distribution in parts of Honduras and, especially, Guatemala. In Panama, estimated density at one site 20 pairs/100 ha, and estimated home range of marked individual at another more than 2.2 ha. A study on Barro Colorado I, also in Panama, produced estimate of 250 individuals present, with the species occupying 80% of the island. Generally a common and widespread species, with preference for forest edge and second growth at many sites suggesting relatively low sensitivity to human disturbance; does, however, require at least patchy forest nearby.

PLATE 36

## PLATE 36

## Family DENDROCOLAPTIDAE (WOODCREEPERS) SPECIES ACCOUNTS

### 34. Ivory-billed Woodcreeper

#### *Xiphorhynchus flavigaster*

French. Grimpur à bec ivoire

German. Strichelbaumsteiger

Spanish. Trepatroncos Picomarfil

Other common names. Laughing Woodcreeper; Stripe-throated Woodcreeper ("striatigularis")

**Taxonomy.** *Xiphorhynchus flavigaster* Swainson, 1827. Temascaltepec, México, Mexico. Sister-species relationship with *X. lachrymosus* has been suggested on basis of molecular data. Assessment of geographic variation is complicated by marked individual variation in coloration, overall size, and pattern of streaking (width and shape) both above and below. Race *mentalis* poorly differentiated from nominate; *saltuarius*, *ascensor* and *ultimus* weakly differentiated from *eburneirostris*. Described form *striatigularis*, known from unique type specimen from S Tamaulipas

(Mexico), sometimes treated as a full species, but recently shown to represent an aberrant individual of present species. Eight subspecies recognized.

#### Subspecies and Distribution.

*X. f. tardus* Bangs & J. L. Peters, 1928 - NW Mexico (SE Sonora, N Sinaloa); intergrading with race *mentalis* in W Durango.

*X. f. mentalis* (Lawrence, 1867) - Coastal W Mexico (C & S Sinaloa S to Michoacán); intergrades with *tardus* in W Durango and with nominate in W Guerrero.

*X. f. flavigaster* Swainson, 1827 - SW Mexico (Guerrero, S Oaxaca).

*X. f. saltuarius* Wetmore, 1942 - NE Mexico (S Tamaulipas and SE San Luis Potosí S to N Veracruz).

*X. f. ascensor* Wetmore & Parkes, 1962 - Caribbean slope of S Mexico from S Veracruz and N Oaxaca E to Tabasco, possibly also N Chiapas E to adjacent Guatemala.

*X. f. yucatanensis* Ridgway, 1909 - Yucatán Peninsula; populations at base of peninsula S to N Belize, possibly to NC Guatemala (Petén), show signs of intergradation with *eburneirostris*.

*X. f. eburneostriis* (Des Murs, 1847) - Caribbean Slope of Central America from C Guatemala and Belize E to Honduras, also locally in N Costa Rica; Pacific slope from S Mexico (extreme SE Oaxaca, S Chiapas) S to NW Costa Rica.  
*X. f. ultimus* Bangs & Griscom, 1932 - hills of Nicoya Peninsula, in NW Costa Rica; possibly intergrading with *eburneostriis* in adjacent lowlands.

**Descriptive notes.** 20-26.5 cm; male 40-62 g, female 35-56g. Relatively large woodcreeper with long, moderately heavy and slightly decurved bill. Nominative race has face finely streaked buffy and blackish, indistinct buffy supercilium and eyering contrasting with weak dark postocular stripe; crown and nape deep greyish-brown with conspicuous pale buff spot-like streaks; back and scapulars light greyish-brown to olive-brown, broadly and extensively streaked buff, each streak narrowly edged blackish; tawny-brown rump contrasts little with cinnamon-rufous to rufous-chestnut wings and tail; median and greater coverts like

back, lessers more rufescent, lesser and median coverts having fine pale shaft streaks, those on medians edged blackish; remiges lighter than tail, outer primaries paler still, less rufescent, with dusky tips; buffy throat finely streaked dusky, separated from submoustachial region by dusky malar stripe; upper breast slightly paler than throat, with blackish-edged feathers producing scaly appearance; rest of underparts light buffy brown with broad dusky-edged buff streaks that weaken towards lower belly; underwing-coverts ochraceous buff; iris light reddish-brown to dark brown; bill pale horn-white, greyish-ivory or pale flesh, base of upper mandible brownish or bluish; legs and feet yellowish-green to olive-grey or brownish. Distinguished from other woodcreepers in range mainly by combination of large size, heavy and relatively straight bill that is largely pale, boldly streaked upperparts, dark malar stripe. Female is slightly smaller than male. Juvenile resembles adult, but slightly darker, throat more boldly streaked, streaks on breast and back duller and with broader black edges, bill brownish. Race *mentalis* is very like nominate, but smaller, with conspicuously shorter bill; *tardus* is much smaller, and paler and greyer both above and below; *yucatanensis* is similar in coloration to *mentalis* but slightly smaller, throat pale buff and unmarked; *eburneostriis* is like nominate but has throat markings limited to a few fine streaks at lower edge, overall coloration darker and browner (less greyish), crown and nape sooty black, back deeper brown, streaking above and below richer buff; *ultimus* is like *eburneostriis* but larger, with bill longer and heavier, upperparts slightly darker, underparts richer buff, streaks below with blacker edges; *saltuarius* is also similar to *eburneostriis* but paler, especially on belly, with streaks above much larger and more prominent, those below less sharply defined; an aberrant individual had throat heavily streaked black, breast streaks with wavy black edges, back streaks broader, wing-covert streaks more broadly edged black and underwing-coverts mottled ("X. striatigularis"); *ascensor* is darkest of all, upperparts richer and darker brown, wings and tail deep chestnut, crown streaked rather than spotted, streaks both above and below broader and more boldly margined with black, those below extending farther down belly. Voice. Song in W Mexico c. 2.5 seconds long, 15-20 piercing whistles in loud cascade that first ascends slightly and increases in volume before descending and slowing, "t-t-t-ttttttt-tewtewtew-tew-tew"; in rest of range a "laughing" whinny 4-7 seconds long, 25-45 clear whistles reaching peak pitch, fastest tempo and greatest volume in first second, then steady for a short period, and eventually fading, slowing and falling, slower than in W Mexico and often likened to song of Canyon Wren (*Catherpes mexicanus*), but sometimes ending in upward-inflected "whee whee-weep" or "weet, weet". Calls include sharp, almost explosive "tchee-oo", "skweel" or "squirp", which in W Mexico can be softer "chehr"; also explosive, descending series of 4-12 notes, "tyew-tyew-tyew" or "s-keé, kee, kee, kee, kee, kee, kur", similar to calls of *X. susurrans*; also a dry rattle like that of woodpecker (Picidae).

**Habitat.** Occupies a variety of wooded habitats from lowlands to middle elevations of foothills. Apparently most common in deciduous woodland, but occurs also in lowland and montane evergreen forests, gallery forest, thorn-scrub, lower reaches of cloudforest, pine-oak (*Pinus-Quercus*) or pine woodland, and both mangroves and freshwater swamps. Found not only in mature forest, but also in second growth, forest edge and plantations; not nearly so dependent on true forest as are most woodcreepers. Unlike most members of family, probably more common in drier situations than in humid forest. Occurs over a wide elevational range, mainly tropical lowlands and foothills from sea-level to c. 1500 m, but at least occasionally into subtropical zone to 2800 m; possibly more common at lower elevations in N, but in foothills in S.

**Food and Feeding.** Diet mostly arthropods, but small vertebrates (principally lizards) also taken. Prey taken over army-ants included a large green orthopteran, also a significant number of lizards (20% of all prey observed taken in one study). Stomachs contained a high diversity of prey; in a study in S Mexico primarily snails (taken in significantly greater quantities than by other woodcreepers at site), beetles, spiders, various orthopterans, ants and caterpillars, but also scorpions and pseudoscorpions, bugs (Hemiptera), planthoppers and cicadas (Homoptera), flies, wasps, and a few lizards. Most prey less than 10 mm in length, but spiders, orthopterans and some beetles on average larger, and caterpillars on average c. 35 mm. Usually alone, but sometimes in pairs, and often as attendant of mixed-species flocks. Considered a core follower, with high propensity for flocking; present in 5-25% of flocks studied at one site in E Mexico, and in 16% of flocks at site in W Mexico (where 82% of observations involved birds with flocks); one study demonstrated significant preference for larger flocks over smaller ones. Also regular attendant of army-ant swarms (*Eciton burchelli*, rarely *Labidus praedator*); single birds present at nearly 30% of swarms studied at site in S Mexico. Forages while hitching in spiral motion up trunks and, especially, branches, mainly from mid-levels to subcanopy, but regularly to canopy, and occasionally down to fallen logs or ground; sometimes reverses downwards or creeps along undersides of branches, like smaller *Lepidocolaptes*. Forages mainly by probing bark crevices, bromeliads and other epiphytes, and, at least on occasion, clusters of dead leaves; at times observed to pry off loose bark to expose hidden prey, tapping lightly on dead branches, or dropping to ground to rummage among dead leaves. An ecologically plastic species that has even been seen to forage for insects on coastal mudflats among stumps left after mangroves were cleared. Over ants, alights low on trunks, dropping to ground to take prey.

**Breeding.** Specimens in breeding condition in late Mar to mid-Aug in N & C of range (Mexico to Honduras); in Mexico, nests with eggs in late Apr to early Jun in NW & E, nestlings in Jun in S, and fledglings being fed in mid-Jun to late Jul in W & S. Nests described have been low, 1-1.7 m up, in cavity amid snag or in gap between fig (*Ficus*) roots and tree, lined with fibres, wood chips or bark

flakes, in one case c. 7.5 cm across. Clutch 2-3 white eggs, average 29 × 21 mm. Annual moult in Aug-Sept overlaps with later nesting attempts.

**Movements.** Apparently resident throughout range; possibly some upslope movement in non-breeding season.

**Status and Conservation.** Not globally threatened. Fairly common to common over most of range (primarily lowlands in Mexico, Belize, Guatemala and Honduras, but in foothills in NW Costa Rica); uncommon and local at upper end of elevational range, and in lowlands of NW & N Costa Rica; now very rare at N limit of range in W Mexico (S Sonora), where previously not uncommon. Estimated density at site in NE Mexico 17.5 pairs/100 ha; home range at site in S Mexico estimated at 4 ha. A generalist species, frequenting both open and closed environments; far less dependent on true forest than are most woodcreepers, possibly an adaptation that allows it to survive at N limit of dendrocolaptid distribution. Consequently, appears only moderately sensitive to human disturbance, provided that patches of forest remain: numbers captured during study on Yucatán Peninsula increased after area was hit by a hurricane (at least where not subsequently burned).

## 35. Black-striped Woodcreeper *Xiphorhynchus lachrymosus*

French: Grimparr maillé German: Schwarzzücken-Baumsteiger Spanish: Trepatroncos Pinto

**Taxonomy.** *Dendroornis lachrymosus* Lawrence, 1862, no locality = Atlantic side of Isthmus of Panama, along line of Panama Railroad, Canal Zone, Panama.

Sister-species relationship with *X. flavigaster* has been suggested on basis of molecular data. Race *eximius* synonymized with nominate by most recent authors, but this resulted in part from apparently mistaken belief that specimens from Caribbean slope in W Panama represented *eximius* instead of nominate. Three subspecies recognized.

### Subspecies and Distribution.

*X. l. lachrymosus* (Lawrence, 1862) - Caribbean slope of Central America in E Nicaragua, Costa Rica and Panama (locally also Pacific slope from Canal Zone E to Darién), also W Colombia (in lower Atrato Valley and along Pacific coast) and NW Ecuador (S to N Pichincha, once to N Manabí).  
*X. l. eximius* (Hellmayr, 1903) - Pacific slope of SW Costa Rica and adjacent W Panama.

*X. l. alarum* Chapman, 1915 - lowlands of N Colombia (valleys of upper R Sinú, lower R Cauca and middle R Magdalena E to Santander).

**Descriptive notes.** 21.5-25 cm; 51-66 g. Strikingly marked, robust woodcreeper with bill relatively long, nearly straight, slightly decurved at tip. Nominative race has brownish-black face evenly streaked buff and without apparent supercilium; crown and nape brownish-black with buff centres of feathers, producing bold pattern of teardrop-shaped spots and broad streaks; back and scapulars similar, but more broadly streaked with deeper buff; lower back, rump and remiges dark cinnamon-rufous, outer primaries tipped dusky; inner greater coverts and lesser coverts at shoulder dark cinnamon-rufous, contrasting with re-

maining wing-coverts, which are mostly brownish-black but with a buffy central streak on medians and rufous centres of greater; tail rufous-chestnut; throat pale to deep buff, posterior feathers narrowly tipped blackish; breast and belly pale buff with brownish-black feather edges, producing scaled effect on breast but more streaked appearance on belly; sides and flanks greyish-brown with indistinct streaking, undertail-coverts brownish (sometimes rufescent) with pale buff streaks; underwing-coverts deep ochraceous buff to tawny-buff; iris dark reddish-brown to dark brown; bill dark brown to black, lower mandible silver-grey to bluish-white (base sometimes yellowish or pinkish); legs and feet green to bluish-grey or dark grey. Sexes similar. Juvenile resembles adult but pattern more muted, black edges duller and browner, also whiter below, throat more heavily scaled with sooty black, bill shorter. Size and striking pattern of black and pale-buff streaking unique among woodcreepers. Race *eximius* is similar to nominate, but black streaking below more distinct and more extensive (continuing boldly throughout belly), upper back more extensively blackish, wings and tail deeper rufous; *alarum* differs from nominate in having buffy spots on back smaller, with feathers margined narrowly with black and then more broadly with dark brown, outer web of greater coverts edged brown rather than black, also spots below smaller. Voice. Song a soft, descending whinny 2.5-4.5 seconds long, comprises 10-35 clear whistles that begin slowly, speed up, then slow at end, "wi, di, di, di, di-di-di-di-di, di, di, dev". Most common call a series of 2-4 loud, descending whistles with laughing quality, described as "weep-weep-whup", "weé-hir-hir" or "weé, ha-há"; also a loud emphatic "doweeet" or "choo-reep" with upward inflection, a descending "cheer" or "chirrrw" with rolling quality and, when agitated, a rapid series of sharp notes that rise and fall in frequency and speed, and vary from clear whistled "weet" to harsh "wik". Juvenile gives a hissing "chwahh", squeaking "screieth", and a squealing "cheir cheir cheir" that may grade into a trill.

**Habitat.** Chiefly humid lowland forest; largely tied to evergreen forest, but ranges into ecologically different mangrove forest at some sites. Mostly in interior of tall, mature forest; also regularly visits forest edge or gaps, older second growth, occasionally tree plantations. Requires somewhat patchy to continuous forest, usually with tall trees nearby. Mostly tropical zone from sea-level to 1000 m; locally higher, in subtropical zone to 1200 m in Costa Rica and 1500 m in Colombia.

**Food and Feeding.** Diet primarily arthropods, but small vertebrates also taken. Most prey caught in association with ant swarms were quite small, but larger items included cockroaches (Blattodea) and grasshoppers (Acrididae), isopods, millipedes (Diplopoda) and centipedes (Chilopoda); stomach contents comprised small to medium-sized beetles, crickets (Gryllidae), ants, cockroaches, Hemipteran bugs, cicadas (Cicadidae), moths, centipedes, spiders and spider egg sacs, also small lizards and a small frog. Larger prey (30-80 mm) often hammered on trunks and crushed in beak before being swallowed whole. Forages singly, sometimes in pairs, rarely three together (usually adults with dependent young). Regular associate of mixed-species flocks of forest canopy, less frequently those in understorey; present in only 11-14% of flocks studied at one Panamanian site, where even roosted in close proximity to other flock-members. Seen away from flocks more often than are many congeners, and noted by some authors as being found alone more often than with flocks. Relatively frequent attendant at swarms of army-ants (mostly *Eciton burchelli*, also *Labidus praedator*). Forages intently while hitching spirally up near vertical trunks and along large horizontal branches, in upper strata of forest from subcanopy to canopy (often 10-20 m up, sometimes to 30-40 m); over ant swarms, most observations of foraging 2-8 m above ground, only rarely below 1 m. Creeps along horizontal limbs far more often than do most woodcreepers, and seems to show special preference for undersides of epiphyte-laden limbs; seems also to prefer larger trunks and limbs, seen mostly on branches 6-25 cm in diameter (few observations on branches less than 5 cm across), occasionally on trunks with diameter in excess of 1 m. Most prey either gleaned from surface of trunks or branches, or caught by probing in vine tangles, clusters of dead or live leaves, epiphytes, clumps of moss, bark crevices or snags; sometimes pries off loose strips of bark, digs into rotten wood with open bill, rummages through dead leaves or debris caught in tree crotches, uses gaping to expose prey hidden in epiphytes; occasionally sallies after flying prey. Over ants forages using techniques similar to those used away from them; prey usually pecked from trunks, vines and leaves, but sometimes dives to take falling prey in mid-air, or sallies to nearby foliage; unlike most ant-following woodcreepers, seems never to sally to the ground to capture prey. Relatively aggressive over ant swarms, where regularly seen to supplant or displace smaller *Dendrocincla fuliginosa*; interactions with *X. susurrans* less frequent and less one-sided, although present species generally dominant; by contrast, usually dominated by larger *Dendrocolaptes sanctithomae*. Other birds attacked on occasion include various antbirds (Thamnophilidae), tanagers (Thraupidae), even puffbirds (Bucconidae) and trogons (Trogonidae). Intraspecific aggression also frequent, with multiple birds only rarely seen together at ant swarms, these usually adults with dependent young.

**Breeding.** Breeds Mar-Jun in Costa Rica; specimens in breeding condition in Feb-May in NW Colombia; fledged young in mid-Jul to mid-Oct in Panama. Pairs rarely observed, prompting one author to suggest that present species may remain unmated for much of year. In mid-Apr to early Jun in Panama, seen to enter narrow slit 1-1.5 m above ground in tree trunk, presumably entrance to nest-cavity; elsewhere, nest located in palm stub or hole in tree, entrance usually 0.6-6 m up, lined with wood chips and bark flakes. Clutch 2 eggs; most observations of families involved single dependent young, but some apparent families with 2 and 3 young.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon to fairly common, or locally common, throughout its range; absent from drier habitats, such as those in NW Costa Rica. Estimated densities at a Panamanian site 5 pairs/100 ha. Study of individually marked birds suggested that they had large and widely overlapping home ranges. Requires relatively continuous forest with tall trees and, therefore, believed to be at least moderately sensitive to forest fragmentation and other forms of human disturbance.

**Bibliography.** Aleixo (2002), Anon. (1998a), Carriker (1910), Chapman (1915b, 1917), Cory & Hellmayr (1925), Dunning (1993), Eisenmann (1952), Elliot (1890a), Gradwohl & Greenberg (1980), Granizo (2002), Greenberg (1981a), Hellmayr (1903b, 1911), Hilty & Brown (1986), Jones (1977), Karr (1971b), Karr, Robinson *et al.* (1990), Lawrence (1862), LeCroy & Sloss (2000), Loiselle (1988), Meyer de Schauensee (1950a, 1950b, 1964), Olivares (1958), Parker & Carr (1992), Peters (1931), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1909, 1911), Robbins *et al.* (1985), Slud (1960, 1964), Stiles (1983b, 1985), Stiles & Levey (1994), Stiles & Skutch (1989), Stone (1918), Sturgis (1928), Wetmore (1972), Willis (1972b, 1980, 1983c), Willis & Eisenmann (1979).

## 36. Spotted Woodcreeper

### *Xiphorhynchus erythropygius*

**French:** Grimpar tacheté **German:** Olivkappen-Baumsteiger **Spanish:** Trepatroncos Manchado  
**Other common names:** Berlepsch's/Ecuadorian/Spot-throated Woodcreeper ("aequatorialis group")

**Taxonomy.** *Dendronis erythropygia* P. L. Slater, 1860, Veracruz and Oaxaca = Jalapa, Veracruz, Mexico.

Suggested sister-species to *X. triangularis* based on genetic comparison using "aequatorialis group". The two sometimes regarded as forming a superspecies, or as conspecific; treatment as separate species supported by molecular evidence, vocalizations, apparent lack of intergradation, and elevational replacement where ranges approach (with at most, very limited sympatry on W slope of Andes in SW Colombia and W Ecuador). On basis of plumage and, to a lesser degree, voice and elevational preference, races divided into "erythropygius group" (including *parvus*) and "aequatorialis group" (including *punctigula* and *insolitus*); races within each group poorly differentiated. Five subspecies recognized.

#### Subspecies and Distribution.

*X. e. erythropygius* (P. L. Slater, 1860) - highlands of C & S Mexico (extreme SE San Luis Potosí and Hidalgo S to C Oaxaca, also Guerrero).

*X. e. parvus* Griscom, 1937 - S Mexican Highlands (extreme SE Oaxaca, Chiapas) and extreme NW El Salvador S to NC Nicaragua; also locally in S Belize.

*X. e. punctigula* (Ridgway, 1889) - SE Nicaragua S to C Panama (E to Veraguas).

*X. e. insolitus* Ridgway, 1909 - C & F Panama (W to Canal Zone) and NW Colombia (S along coast to N Chocó, also lower Cauca Valley (C Antioquia) and middle Magdalena Valley S to N Caldas).

*X. e. aequatorialis* (Berlepsch & Taczanowski, 1884) - Pacific slope of W Andes from W Colombia (S from C Chocó, also upper Atrato Valley) S to SW Ecuador (S to W Loja).

**Descriptive notes.** 19-24 cm; male 40-54 g, female 40-46 g. Medium-sized woodcreeper with bill relatively long, slightly decurved and gradually tapering. Nominate race has distinct buff eyering continuous with buff supercilium, dusky lores, auriculars dusky olive streaked buff; crown and nape dark olive to brownish-olive, feathers finely spotted buff and with narrow dusky fringe; back and wing-coverts brownish-olive to tawny-brown, back broadly streaked or spotted buff, rump deep cinnamon-rufous; remiges rufous-chestnut, most edged olive-brown, primaries tipped dusky; tail rufous-chestnut; throat and foreneck buffy with feathers tipped dark olive, producing a narrowly barred effect; underparts pale greenish-olive with large teardrop-shaped spots of buff that fade on flanks and undertail-coverts, which are cinnamon distally; underwing-coverts deep buff; iris dark brown; upper mandible blackish to dark brown with a whitish to pale grey stripe along cutting edges (at least in Central American birds), lower mandible whitish-horn

to pinkish-grey; legs and feet blue or greenish-grey to slate-grey. Distinguished by olive to brownish-olive coloration, buffy eyering, and boldly spotted underparts combined with long, bicoloured bill: "aequatorialis group" similar to *X. triangularis* but crown largely unmarked (at most a few fine streaks on forehead), eyering and throat buffier, throat finely spotted instead of scaled, back more heavily streaked, spots below larger, rump more extensively rufous. Female is slightly smaller than male. Juvenile is similar to adult, but browner overall, spotting below less distinct, especially on throat and belly. Race *parvus* is

similar to nominate but smaller, more rufescent above, more greenish-olive below, and throat slightly buffier and spotted rather than barred. Members of "aequatorialis group" are smaller, more greenish-olive overall, crown with only fine streaks limited to forehead, back unmarked or with finer streaks on upper back only, throat more yellowish-buff and with small dusky spots (not bars), fewer and smaller spots below, bill relatively straight and abruptly tapering only at tip; *punctigula* is very similar to *aequatorialis*, but underparts deeper olive with spots smaller and less rounded, throat more densely spotted, rump and wings lighter rufous; *insolitus* is like *punctigula* but may average slightly darker above and browner overall. **Voice.** Relatively vocal. Song, given intermittently, mostly at dawn and dusk (less frequently during day), a series 4-6.5 seconds long of 2-5 (usually 3-4) long descending whistles, each at progressively lower pitch, and sometimes followed by 1-2 additional notes at same pitch; notes either clear, rather plaintive whistles transcribed as slowing "wheeeoo, wheeeoo, wheeeoo, wheeeoo" in Mexico ("erythropygius group"), or quavering whinnies as "piiiiiiiiiiiiir, piiiiiiiiiiiiir, piiiiiiiiiiiiir", "d'ddrear, d'ddrear, d'ddrear, whew, whew" or "d-d-d-r-reeuw, d-d-d-r-reeuw, d-d-d-r-reeuw" from Costa Rica S to Ecuador ("aequatorialis group"). Calls include whistled "wheeeoo" or "hee-e-e-e-cw", a descending "jeeu" or "djeer" that is weaker and shorter than call of *X. susurrans*, and a low, hen-like "cut-uck".

**Habitat.** Humid forest in both lowlands and upper elevations. Elevational preferences vary geographically, with N populations chiefly in montane evergreen forest, cloudforest, and pine-oak (*Pinus-Quercus*) and pine woodlands of upper elevations; S populations also frequent tall evergreen forest of tropical lowlands. Seems to prefer forest heavily laden with mosses and epiphytes, not only in mountains but also where it occurs in lowlands; has been suggested as being better adapted than *X. susurrans* to traversing epiphyte-covered branches as a result of its short legs and tail, but long claws. Generally in canopy and interior of mature forest, but regularly visits forest edge, older second growth, and even tree plantations or scattered trees near forest. Mostly in upper tropical and lower subtropical zones at 600-1800 m, locally to 2200 m (occasionally 2500 m) or down to 300 m; exceptionally, near sea-level in Costa Rica, W Colombia and W Ecuador.

**Food and Feeding.** Diet mostly arthropods, but small vertebrates and, occasionally, vegetable matter also taken. Primarily cockroaches (Blattodea), beetles, crickets (Gryllidae), earwigs (Dermaptera), and spiders, less frequently small frogs and salamanders; seen feeding a large katydid (Tettigoniidae) to grown young. Stomach contents included mainly medium-sized beetles, but also a cockroach and other insects, and even seeds and fruit pulp from an unidentified melostome (Melostomataceae). Larger prey often beaten vigorously before being swallowed. Forages singly, less often in pairs, occasionally in family groups. Regular associate of mixed-species flocks of both understorey and canopy; marked seasonal variation in length of time spent with flocks, with individually marked birds at site in Costa Rica dropping out of flocks entirely in Jun-Jul, but remaining with them for average of 90 minutes at a time in Feb; present in 13% of flocks at site, but left when flocks reached boundary of its home range on 49% of occasions. Significant preference for flocks containing Golden-crowned Warbler (*Basileuterus culicivorus*), Common Bush-tanager (*Chlorospingus ophthalmicus*) and Lined Foliage-gleaner (*Syndactyla subalaris*). Adults with fledged young usually join flocks separately, each adult accompanied by a juvenile. Sometimes attends army ants (*Eciton burchelli*), usually singly. Forages primarily while hitching up trunks and especially along large branches, often with spiralling motion and regularly on undersides of horizontal branches, from mid-levels to canopy; less frequently closer to ground, down to 0.5 m, especially when at ant swarms. Most prey taken either from surface of trunks or branches by gleaning, or from clusters of dead leaves, epiphytes, clumps of moss, tree-ferns, bark crevices or snags and vine tangles by probing or rummaging; sometimes pries or flakes bark. In association with ant swarms, forages while hitching up near-vertical trunks, usually in excess of 6 cm in diameter and at heights 0.5 to 11 m above ground, by using techniques similar to those used away from ants. Special interest in epiphytes has been suggested.

**Breeding.** Breeds Mar-Jun in Costa Rica and in Panama (where also seen feeding young out of nest in late Aug); in NW Colombia, breeding-condition birds in Feb-May and nest found in mid-Sept; birds in breeding condition in Apr in S Mexico and late Jun in W Panama. Nest in cavity of palm stub or dead stump, entrance usually 2-10 m up. Clutch 2 eggs.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common or locally common in humid foothill and lower montane forests throughout range; decidedly scarce or absent in drier habitats, and uncommon near lower elevational limit. One individually marked bird in Costa Rica had a home range of 3 ha. Requires continuous to somewhat patchy forest, and thus believed to be at least moderately sensitive to forest fragmentation and other forms of human disturbance. An indicator of upper tropical montane evergreen forest of Madrean and Chiriqui-Darién Highlands in Central America, and of N Andes of South America.

**Bibliography.** Aleixo (2002), Anon. (1998a), Berlepsch & Taczanowski (1883), Binford (1989), Bjelland & Ray (1977), Blake, E.R. (1953), Blake, J.G. (1989), Blake, J.G. & Loiselle (1991), Buskirk (1976), Carriker (1910), Chapman (1917, 1926), Cory & Hellmayr (1925), Davis (1972), Edwards (1972), Edwards & Lea (1955), Eisenmann (1955), Elliot (1890a), Gómez de Silva *et al.* (1999), Griscom (1932b, 1937), Hartman (1961), Hellmayr (1911), Hilty (1997), Hilty & Brown (1986), Howell & Webb (1995a), Jones & Valley (2001), Karr, Robinson *et al.* (1990), Land (1962, 1970), Marshall (1943), Meyer de Schauensee (1950a, 1964), Miller *et al.* (1957), Monroe (1968), Navarro (1992), Orians (1969), Parker (1993), Parker & Carr (1992), Paynter (1957), Peterson & Chalif (1973), Powell (1979), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1889, 1909, 1911), Robbins *et al.* (1985), Slater (1889), Slud (1960, 1964), Stiles (1983b, 1985), Stiles & Levey (1994), Stiles & Skutch (1989), Stotz *et al.* (1996), Sturgis (1928), Wetmore (1944, 1972), Willis (1983c).

## 37. Olive-backed Woodcreeper

### *Xiphorhynchus triangularis*

**French:** Grimpar à dos olive

**Spanish:** Trepatroncos Dorsioliva  
**German:** Olivrücken-Baumsteiger

**Taxonomy.** *Dendrocolaptes triangularis* Lafresnaye, 1842, Bolivia; error = "Santa Fe de Bogotá", Colombia.

Sister-species to *X. erythropygius*. The two sometimes regarded as forming a superspecies, or as conspecific; treatment as separate species supported by molecular evidence, vocalizations, apparent lack of intergradation, and elevational replacement where ranges approach (at most, very limited sympatry on W slope of Andes in SW Colombia and W Ecuador). Described race *distinctus* (from W Andes of Colombia) synonymized with nominate; *hyalodromus* differs only slightly from nominate, but is geographically disjunct; *intermedius* intergrades with and possibly indistinguishable from *bangsi*. Four subspecies recognized.

### Subspecies and Distribution.

*X. t. hylodromus* Wetmore, 1939 - coastal and interior mountains of N Venezuela (Andes in Trujillo and SE Lara, Yaracuy E to Miranda and Distrito Federal).

*X. t. triangularis* (Lafresnaye, 1842) - Andes of W Venezuela (Zulia, SW Táchira, Mérida), Colombia (W, C & E cordilleras except in W Nariño), E Ecuador and N Peru (N of R Marañón).

*X. t. intermedius* Carriker, 1935 - Andes of C Peru (Pasco, Junín).

*X. t. bangsi* Chapman, 1919 - E Andean slopes from SE Peru S to C Bolivia (La Paz, Cochabamba, W Santa Cruz), intergrades with *intermedius* in SE Peru.

**Descriptives.** 19.5-25 cm; male 40-52 g, female 32-48 g (57 g when laying). Medium-sized woodpecker with bill slightly decurved and about as long as head is wide. Nominate race has narrow buffy-white eyering and supercilium standing out against finely streaked face; crown and nape blackish-brown with elongate spots of pale buff; back, wing-coverts and most of rump bright olive to brownish-olive, upper back with scattered spot-like streaks of buff; uppertail-coverts cinnamon to rufous-chestnut; remiges with inner webs cinnamon to rufous-chestnut but outer webs bright olive (rufous in wings relatively inconspicuous), tips of

primaries dusky; tail dark rufous-chestnut; throat buffy-white, feathers with blackish-brown margins producing heavily spotted appearance (especially on lower throat); dark olive below, slightly paler than above, breast heavily spotted buffy whitish, spots becoming longer and more triangular towards belly, flanks largely unmarked, undertail-coverts finely streaked; underwing-coverts ochraceous; iris dark brown; upper mandible horn-black on culmen and base, whitish to bluish-ivory along side, lower mandible grey with paler spots on side (extent of black and whitish on bill may vary geographically); legs and feet blue-grey to grey with slight olive cast. Distinguished from "*aequatorialis* group" of *X. erythropygus* mainly by more olive upperparts: more boldly spotted crown; paler and more rufous rump, wings and tail; paler throat and breast with scaly instead of spotted pattern; uniformly darker bill. Female is slightly smaller than male. Juvenile is duller than adult, with smaller spots on breast. Race *hydrolodrum* is closely similar to nominate, but brighter olive-brown above, secondaries darker and less reddish, throat paler with finer scaling, underparts lighter, more greenish-olive, and more heavily spotted; *bangsii* is also like nominate, but upperparts more rufescent (less olive) with rufous extending onto rump, crown spots larger, back more distinctly streaked, throat more whitish with fringes more olive (less blackish), spots below smaller and not extending to belly (which is narrowly streaked), undertail-coverts more finely streaked and more rufescent, bill mostly whitish with black restricted to base and tip of upper mandible; *intermedius* is intermediate between nominate and *bangsii*, being slightly browner above than nominate, and with underparts paler and browner. VOICE. Poorly known, apparently rather quiet. Song a series of hard notes that accelerates then slows, "we we we-we-we-we-WE-WE-we-we-wa"; faint song, often given repeatedly, a weak and somewhat nasal series that accelerates into a slow trill, "quee, quee QUEE-que-que-e'e'e'e". Call most often described as penetrating downslurred "keeweeeuu" or shorter "wheeer" whistle with slightly nasal ending, sometimes interspersed with a string of semi-musical notes; another call a soft series c. 1 second long of c. 15 notes, "wik-ti-ti-ti....ti-tew".

**Habitat.** Primarily evergreen forest in middle elevations of Andes. Most common in humid and very humid montane evergreen forest and cloudforest; at upper elevations sometimes in slightly stunted forest. Largely in interior of mature forest, but sometimes in older second growth or forest edge. Chiefly upper tropical and subtropical zones at 1000-2400 m; occasionally to 2700 m in Colombia and Peru, and down to 800 m in W Colombia and to 400 m on E slope of Andes in SE Colombia and Bolivia.

**Food and Feeding.** Diet not described in detail; presumably mostly insectivorous. Forages primarily by hitching up trunks, moss-covered branches and large vines, from mid-levels to subcanopy, but sometimes into canopy or closer to ground (mostly 2.5-13 m). Like most members of genus appears to forage largely by inspecting clumps of moss, less often by gleaning prey from bark surface, or probing into bark crevices and epiphytes. Forages singly or in pairs, occasionally small groups, sometimes with mixed-species flocks; presence in flocks at some sites positively correlated with that of Linedate Foliage-gleaner (*Syndactyla subularis*). Hitches up trunks, branches and large vines, from mid-levels to subcanopy, sometimes into canopy, or at times closer to ground, mostly at 2.5-13 m; seeks food mainly on moss-covered branches. Appears to forage largely by gleaning prey from bark surface or by probing into bark crevices and epiphytes; methods seemingly as for most members of genus.

**Breeding.** Season Apr-Jun in N Venezuela; in Colombia, birds in breeding condition in Apr-Jun in W & C Andes, and both a breeding-condition bird in Sept and a juvenile also in Sept in E Andes; a laying female was in body moult in mid-Apr, as were birds in mid-Sept and mid-Dec (Colombia). No other information available.

**Movements.** Apparently resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in montane forests throughout its range. Largely restricted to mature forest, and therefore believed to be highly sensitive to human disturbance. An indicator species for montane evergreen forest in upper tropical zone of C Andes.

**Bibliography.** Aleixo (2002), Berlepsch & Stolzmann (1896), Bond (1953), Bond & Meyer de Schauensee (1940), Carriker (1935b), Chapman (1917, 1919), Clements & Shany (2001), Cory & Hellmayr (1925), Elliot (1890a), Ejlselds & Krabbe (1990), Hellmayr (1911, 1920), Hilty (1997, 2003a), Hilty & Brown (1986), Meyer de Schauensee (1950a, 1964), Meyer de Schauensee & Phelps (1978), Miller (1963), Parker & Bailey (1991), Parker *et al.* (1985), Phelps & Phelps (1963), Pitman *et al.* (2002), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schäfer & Phelps (1954), Selater (1889), Stotz *et al.* (1996), Taczanowski (1884), Taczanowski & Berlepsch (1885), Wetmore (1939).

**Other common names:** Plain-throated Woodcreeper ("*picrostris* group")

**Taxonomy.** *Oriolus Picus* J. F. Gmelin, 1788, in Gujanae = "Cayenne".

formerly placed along with *X. kienierii* in a separate genus, *Dendroplex*, based on morphological differences, but both later merged with *Xiphorhynchus* because of problems with identification of sketch designated as type of *Dendroplex*; morphological distinction of *Dendroplex* supported by recent analysis of molecular data, which suggested that these species are distantly related to present congeners, and closer to *Lepidocolaptes* and *Campylorhynchus*. Holotype of *Dendrognis* [= *Xiphorhynchus*] *Kienierii*, subsequently recognized as a subspecies of *X. picus* by most authors, recently found to match more recently described "*Dendroplex necopinus*", which is supported as specifically distinct from *X. picus* by vocal, ecological and molecular data. Assessment of geographic variation is complicated by marked individual variation, at least in some populations. Races fall into two groups, "*picrostris* group" (also including *choicus*, *extimus*, *dugandi*, *paraguanae*, *longirostris*, *phalara*) in Panama and N & NW South America, with remaining races constituting "*picus* group" of Amazonia and E South America; these groups treated as separate species by some authors, but not by others because of apparent hybrids from lower R Orinoco region of Venezuela; further work needed. Races similar within each group. Purported races *bahiae* (NE Brazil) and *rufescens* (NC Brazil) described on basis of average differences from nominate, but individual variation so marked that neither is considered diagnosable. Described race *borreroi* from S Colombia (E base of Andes in Caquetá) apparently not distinguishable from *peruvianus*, which itself is possibly indistinguishable from *saturator*. Race *choicus* poorly differentiated from *picrostris*. Thirteen subspecies recognized.

### Subspecies and Distribution.

*X. p. extimus* (Griscom, 1927) - C & E Panama (Pacific slope from E Azuero Peninsula E to Darién, also Caribbean slope locally in Canal Zone) and NW Colombia (valleys of lower R Atrato and upper R Sinú, in Córdoba).

*X. p. dugandi* (Wetmore & Phelps, Sr., 1946) - NW Colombian lowlands from S Santa Marta region E to Perijá Mts. and S along Pacific coast to N Chocó and in Magdalena Valley to N Huila.

*X. p. picrostris* (Lafresnaye, 1847) - coastal lowlands of N Colombia (NW Santa Marta region E to Guajira Peninsula) and extreme NW Venezuela (E to mouth of L. Maracaibo).

*X. p. paraguanae* Phelps, Sr. & Phelps, Jr., 1962 - NW Venezuela (Falcón, N Lara).

*X. p. choicus* (Wetmore & Phelps, Sr., 1946) - coastal NC Venezuela (E Falcón E to Miranda).

*X. p. longirostris* (Richmond, 1896) - Margarita I, off N Venezuela.

*X. p. phalara* (Wetmore, 1939) - N Venezuela (Ilanos of interior from Portuguesa, W Apure and NW Bolívar E to E Anzoátegui, and along NE coast E to Sucre).

*X. p. saturation* (Hellmayr, 1925) - E base of E Andes in Colombia (Norte de Santander S probably to Meta) and W Venezuela (C & S Maracaibo basin in S Zulia, NW Táchira, W Mérida).

*X. p. duidae* (J. T. Zimmer, 1934) - upper R Orinoco and upper R Negro in E Colombia (E Vichada), S Venezuela (NW Bolivar, N Amazonas) and adjacent NW Brazil.

*X. p. altirostris* (Léotaud, 1866) - Trinidad.  
*X. p. deltanus* Phelps, Sr. & Phelps, Jr., 1952 - NE Venezuela (Delta Amacuro).

*X. p. picus* (J. F. Gmelin, 1788) - S Venezuela (S Anzoátegui, S Monagas, E Bolívar), the Guianas and N & E Brazil (lower R Negro E to Amapá and, S of Amazon, from R Madeira E to Ceará and

Pernambuco, S to Goiás and, on Atlantic coast, to N Rio de Janeiro); unclear whether birds in SW Brazil (Pantanal) or those in NW Brazil (N bank of R Solimões) and adjacent SE Colombia & NE Ecuador refer to nominate race or *peruvianus*.

*X. p. peruvianus* (J. T. Zimmer, 1934) - SW Amazonia, S of Amazon, from E Peru and W Amazonian Brazil (E to R Juruá, possibly to R Madeira) S to N & E Bolivia (S to Cochabamba and Santa Cruz).

**Descriptive notes.** 18–22 cm; male 34–42 g, female 33–45 g (mainland), female 51 g (*altirostris*). Slim, medium-sized woodcreeper with a distinctive bill combining straight culmen with upward-sweeping lower mandible. Nominate race has indistinct whitish eyering (most evident below eye) and weak supercilium contrasting with dusky postocular stripe, brown auriculars with bold buffy-white streaking; forehead whitish; crown and nape dark brown to blackish with buffy-white streaks, these increasing in size and length on nape; back, scapulars and lesser coverts warm olive-brown to reddish-brown, with at most a

new fine streaks on upper back, remaining wing-coverts mostly rufescent; lower back, rump, remiges and tail rufous-chestnut; primaries and outer secondaries tipped dusky brown, these tips increasing in extent on outermost primaries; central rectrices darker than outers, thus contrasting with rump; chin and throat buffy white, feathers of throat narrowly fringed dark brown to black, indistinct malar stripe separating buffy submoustachial region from throat; lower throat and upper breast with oval centres of feathers pale buff surrounded by black fringes that continue uninterrupted around tip, resulting in boldly scaled appearance; remaining underparts brown, sometimes more olive on belly; scaling of upper breast becomes narrower and more linear on lower breast, upper belly, sides and flanks, leaving belly largely unmarked but undertail-coverts again have buffy-whitish streaks; underwing-coverts cinnamon-rufous; iris reddish-brown to dark brown; bill light greyish-horn or brownish to dull whitish (sometimes with pinkish or lilac tinge), base of upper mandible dusky or blackish, lower mandible often paler; legs and feet various shades of green, grey, bluish-grey or brownish. Distinguished from very similar *X. kienerii* by straighter to slightly upturned bill, more scaly pattern on breast (more oval feather centres, complete fringes), more brownish or olive cast on belly, more rufescent tone of lesser coverts, proportionately shorter wings and tail, also by differences in vocalizations. Also similar to *X. obsoletus* but bill slightly paler and less decurved, back and underparts less boldly and less extensively streaked, overall coloration more rufescent (less olive), and vocalizations markedly different. Sexes similar. Juvenile similar, but plumage darker overall with patterns more muted, spots or streaks smaller, throat deeper buff, streaking below more extensive and deeper buff in color, and bill shorter and darker. Races vary in overall colour, face pattern, size and shape of breast spots, and throat colour. In "picus group", populations of nominate in SE Amazonia ("*rufescens*") and NE Brazil ("*bahiae*") on average more rufescent and with streaking above and below both broader and more extensive, but many individuals cannot be distinguished: *saturation* is like nominate but much darker, especially below, breast streaking more limited in extent, tail longer; *duidae* is also similar, but throat pure white, back browner, breast spotting more extensive and outlined with black, belly more strongly streaked; *deltanus* is similar to *duidae* but darker overall, with darker bill (also crown and tail darker, mantle more heavily streaked than nominate); *altirostris* is similar to nominate, but wing and bill longer, bill heavier and more strongly curved, spots on underparts larger, better defined and more extensive; *peruvianus* is brighter and more rufescent than nominate, especially above, with throat deeper

**Bibliography.** Aleixo (2002), Aleixo & Whitney (2002), Bangs & Penard (1921), Borges *et al.* (2001), Clements & Shany (2001), Cory & Hellmayr (1925), Griscom & Greenway (1941), Gyldenstolpe (1945a, 1951), Hellmayr (1910), Hilty (2003a), Marantz (1996), Mazar Barnett & Kirwan (2002b), Menegaux & Hellmayr (1906a), Meyer de Schauensee (1966), Pinto (1947, 1978), Ridgely & Tudor (1994), Sick (1993), Sneath (1908, 1909), Stone & Roberts (1934), Stoltz *et al.* (1996), Zimmer (1934c).

On following pages: 42. Lineated Woodcreeper (*Lepidocolaptes albolineatus*); 43. Spot-crowned Woodcreeper (*Lepidocolaptes affinis*); 44. Montane Woodcreeper (*Lepidocolaptes lacrymiger*); 45. Streak-headed Woodcreeper (*Lepidocolaptes souleyetii*); 46. Scaled Woodcreeper (*Lepidocolaptes squamatus*); 47. Scalloped Woodcreeper (*Lepidocolaptes falcinellus*).

**Descriptive notes.** 19–22 cm; 28–38 g. Relatively small to mid-sized, slim woodcreeper with slender slightly decurved bill. Nominate race has side of head and neck dusky brown with bold buff streaks; dark brown crown and nape boldly marked with buffy spots or diamonds (sometimes continuing as fine streaks onto upper back), back and wing-coverts plain brown, rump rufous-cinnamon, remiges and tail rufous-chestnut. remiges edged brown, primaries tipped dusky brown; throat unmarked buff.

conspicuous black malar stripe; underparts olive-brown, lowermost throat down to belly with broad black-edged buffy streaks, streaks becoming progressively weaker, and with dark edges less distinct, on flanks and undertail-coverts, the latter tinged cinnamon; underwing-coverts ochraceous buff; iris dark brown; bill bluish-flesh, pale grey, yellowish or dark brown, base often darker and browner, tip paler, silvery horn; legs and feet lead-grey to dull green. Distinguished from *L. lacrymiger* by somewhat larger size, more obviously streaked back, more richly buff throat; from closely similar *L. souleyetii* by spotted (not streaked) crown, less obviously spotted (not streaked) crown, less obviously spotted (not streaked) crown. Juvenile is similar to adult but darker overall, streaking below with less distinct borders, spotting on crown less conspicuous, bill shorter and darker. Race *lignicida* is much paler and greyer than nominate, both above and below; *neglectus* is browner, less olivaceous, with streaking below broader and paler, almost whitish, thus contrasting with deeper buff throat. Voice. Song a single nasal note followed by rapid, high-frequency trill of c. 20 notes that lasts 2-3 seconds, with last 4-5 notes slower and dropping in pitch, described as "syeehr, see-see-see-see-syn" or "deeeeee hihihihihihih". Other vocalizations are a series of 3-4 reedy squeaks, as "suc, swee-tswew-tswew" or "tsew, tsei-tsei"; also plaintive "cheeyup" or "deeee-deeeeh", and "huip" or squeaky "deek" that sometimes precedes a rattle like that of Hairy Woodpecker (*Picoides villosus*). All vocalizations sharper than those of *L. souleyetii*.

**Habitat.** Humid and dry forests, primarily in highlands. Most common in humid montane evergreen forest and cloudforest, and in drier deciduous, oak (*Quercus*), pine (*Pinus*) and pine-oak woodlands; reaches timber-line in some places, but during winter also descends rarely to upper reaches of lowland rainforest or arid hill country. Frequents interior of mature forest, but possibly more common in older second growth, fragmented forest, and forest edge; also occurs in plantations, and on scattered trees in highland clearings and pastures. Roosts singly in tree cavities, retiring late at dusk and leaving in pre-dawn hours. Mostly subtropical zone, less often upper tropical and temperate zones, 1200-3100 m, occasionally to 3600 m, or down to 750 m (rarely 400 m), especially during winter; apparently descends lower on Caribbean slope (to 1200 m, rarely 750 m) than on Pacific slope (to 1500 m) in Costa Rica. Elevational overlap with *L. souleyetii* minimal on Caribbean slope (and at elevation where both species are scarce), but the two completely separated on Pacific slope.

**Food and Feeding.** Chiefly insectivorous. Contents of one stomach 90% arthropods, with nearly 40% of total representing various beetles; in another study, with larger sample sizes, most prey were beetles or egg cases, with various orthopterans, spiders, insect larvae, earwigs (Dermaptera), bugs and other items also taken. Relatively little prey taken is of type that actively flies to escape predation. Single birds, less frequently pairs, are regular attendants of mixed-species flocks; present in 63-67% of flocks encountered in one study, but only 25% in another; more often associates with flocks than does *L. souleyetii*, but sometimes found in same flocks. Sometimes forages at swarms of army ants (both *Eciton burchelli* and *Labidus praedator*); at one Panamanian site, present at 20-25% and 8-10% of swarms encountered in continuous forest and shade-coffee plantations, respectively. Forages primarily on moss-covered and epiphyte-covered branches, mostly by rapidly hitching up trunks and large branches from mid-levels to subcanopy, often with spiralling motion; less frequently closer to ground or in canopy. At a site in Costa Rica, foraged in relatively open situations, mostly between half and two-thirds up trees, on branches with average diameter 25 cm. Most prey obtained from bromeliads and other epiphytes, lichens, mosses, bark crevices or other substrates, by probing with slim bill (c. 60% in one study); significant percentage also taken after prying or lifting substrates to extract prey hidden beneath (just over 15% of total). Specializes on epiphyte-searching, at least at some sites, with nearly 75% of foraging attempts involving epiphytes (especially mat bryophytes and foliose lichens).

**Breeding.** Breeds Mar-Jun throughout range; pairs inspecting nest sites in late Mar in Costa Rica and Panama; nests with eggs mid-Apr to early Jun and with young late Apr to late Jun in Mexico and Costa Rica, also nestlings in latter period in Guatemala; adult with dependent juvenile in late Jun in El Salvador. Adults in breeding condition in early Mar to mid-May in Mexico and El Salvador. Remains paired throughout year, but apparently only single brood reared annually. Nest, prepared by both adults, comprises small flakes of hard bark (new flakes brought when parents return to incubate, old ones removed when they leave), placed in natural cavity or old hole of woodpecker (Picidae) or barbet (Capitonidae) in tree or stump, nest often in clearing near forest edge, and usually at mid-level or below, 0.6-9 m above ground; one cavity was just over 25 cm deep, interior width 15-22.5 cm, entrance hole only 2.5 × 5 cm. Clutch 2 pure white eggs, sometimes 3, average 30 × 21 mm; incubation by both sexes over period of 17 days, adults at one nest incubated 82% of time under observation, in sessions of 6-47 minutes (average 27 minutes); hatching is covered with grey down and has mouth-lining deep yellow, gape-flanges whitish, eyes closed; young fed frequently, by both parents (with insect larvae, also spiders, cockroaches and other items), at one nest 15 food deliveries per hour when young 13 days old, nestling period 19 days during which young are quite vocal; fledglings fed by parents for at least 1 month, young do not return to nest after fledging.

**Movements.** Largely resident; after breeding season, a few birds may descend into lowlands on Caribbean slope.

**Status and Conservation.** Not globally threatened. Fairly common to common in humid forest throughout entire range from Mexico S to W Panama, including El Salvador; uncommon to rare at lower elevational limit. Densities in three habitats in El Salvador estimated at 0.26-0.40 pairs/ha. Although this species requires at least patches of forest nearby, it is apparently less dependent on continuous forest than are many woodcreepers; is therefore considered only moderately sensitive to human disturbance.

## 44. Montane Woodcreeper

### *Lepidocolaptes lacrymiger*

**French:** Grimpard montagnard **German:** Bergwald-Baumsteiger **Spanish:** Trepatroncos Montano

**Taxonomy.** *Dendrocolaptes lacrymiger* Des Murs, 1849, Mexico; error = "Santa Fe de Bogotá", Colombia.

Forms a superspecies with *L. affinis*, and treated as conspecific by most recent authors; separated on grounds of differences in plumage and voice, although vocal characters yet to be analysed in detail. Races can be divided into two groups based on morphology: N "*lacrymiger* group", also including *sneiderni* (which intergrades with nominate in Bogotá region of Colombia), *sanctaeartae* and *lafresnayi*; and S "*warszewiczi* group", also including weakly differentiated races *aequatorialis*, *carabayae*, *bolivianus* and *frigidus*. Nine subspecies recognized.

#### Subspecies and Distribution.

*L. l. sanctaeartae* (Chapman, 1912) - N Colombia (Santa Marta region).

*L. l. lacrymiger* (Des Murs, 1849) - E Andes of Colombia (from Norte de Santander S to Bogotá); also adjacent W Venezuela (Perijá Mts, Mérida Andes).

*L. l. lafresnayi* (Cabanis & Heine, 1859) - coastal cordillera of N Venezuela (Carabobo E to Miranda, and SW Sucre; recent sight record from Lara probably involved this race).

*L. l. sneiderni* Meyer de Schauensee, 1945 - Colombia S from Bogotá (except Nariño), on both slopes of W & C Andes and W slope of E range, also upper Cauca and Magdalena Valleys.

*L. l. frigidus* Meyer de Schauensee, 1951 - S Colombia (E Andean slopes in Nariño).

*L. l. aequatorialis* (Menegaux, 1912) - Pacific slope of Andes in Nariño (SW Colombia), both slopes in Ecuador (in W, S to Loja); unclear whether birds on W Slope in NW Peru refer to *aequatorialis* or *warszewiczi*.

*L. l. warszewiczi* (Cabanis & Heine, 1859) - E slope of Andes in extreme SE Ecuador and N & C Peru (Cajamarca and Amazonas S to Junin).

*L. l. carabayae* Hellmayr, 1920 - E slope of Andes in SE Peru (Cuzco, Puno).

*L. l. bolivianus* (Chapman, 1919) - E slope of Andes in NE & C Bolivia (La Paz, Cochabamba, W Santa Cruz).

**Descriptive notes.** 19-19.5 cm; male 31-35 g, female 29.5-33 g. Relatively small to medium-sized woodcreeper with slim, slightly decurved bill c. 1.5 times as long as head is wide. Nominative race has boldly streaked face, auriculars and neck, contrasting whitish supercilium (often broken); crown and nape dusky brown conspicuously dotted with whitish-buff and tipped black, these spots weaker and more streak-like on nape, and generally lacking on upper back; back uniformly rufous-brown, rump, wings and tail rufous-chestnut; throat feathers whitish to whitish-buff, edged black; underparts olive-brown with long, broad streaks of white to buffy whitish, each edged and tipped sharply with black (producing a somewhat scaly pattern); iris dark brown; bill dusky grey to bluish-horn, upper mandible more blackish, lower mandible pale grey to whitish; legs and feet olive-grey to dark horn. Differs from *L. affinis* in slightly smaller size, less richly buff throat, less obviously streaked back; Amazonian *L. albolineatus* lacks obvious spotting on crown, and *L. souleyetii* has crown streaked rather than spotted and this streaking is duller, fuzzier, and extends more extensively onto back. Male is slightly larger than female. Juvenile is similar to adult, but bill shorter and darker, streaks below less obviously tapered and only weakly edged with black dots. Members of "*lacrymiger* group" have throat feathers fringed black, and streaks below more rounded distally and both tipped and edged black, both resulting in a somewhat scaly pattern; race *sneiderni* is darker, more olive-grey overall, spots below fewer, smaller and more drop-like; *sanctaeartae* is similar to nominate, but throat paler and less obviously marked, underparts slightly greyer with streaks broader, whiter and edged (but not tipped) blackish; *lafresnayi* is similar to nominate but much paler below and more olive-brown overall, lacking rufescent tones of other races. Most members of "*warszewiczi* group" darker and more rufescent both above and below, with back more obviously streaked, throat buffy and largely unmarked, markings below deeper buff and more streak-like (more linear, and edged but not tipped black); *aequatorialis* is closely similar to *warszewiczi* but slightly more rufescent below, with throat more buffy, streaking below broader; *frigidus* is similar to *aequatorialis* but with bill darker, upperparts more olivaceous, wings longer; *carabayae* is like *warszewiczi*, but overall slightly darker, underparts more olive and more narrowly streaked, bill conspicuously shorter and more strongly curved, upper mandible largely whitish; *bolivianus* has bill shape and colour like *carabayae*, but throat more buffy, upperparts paler and less rufescent, underparts much more olivaceous with streaking broader and whiter.

**Voice.** Generally quiet. Song a 2-5 second series of 10-15 high-pitched whistles that accelerates and descends: "tsip, tsip, tsip, ts-ts-see-see, tsee, tsee-tsee-tsee-tsee" or "tsee, tsee, tsip-tsip, tsee-tsee-tsee-tsee". Other vocalizations described as series of 3 reedy squeaks ("tsee-tsee-tsee-see"), double-noted cry, and a rattle with introductory "ah".

**Habitat.** Occurs in a variety of forested habitats, primarily in middle and upper elevations. Most common in montane evergreen forest and cloudforest, but also occurs in more open woodland, montane deciduous forest, and stunted forest at high elevations (almost to tree-line). Frequents interior of mature forest, but possibly more common in older second growth and forest edge, and even found on scattered trees in highland pastures and other clearings. Mostly in subtropical zone at 1750-3000 m; less frequently upper tropical zone, rarely down to 900 m in N Venezuela and 1000-1200 m in N & W Colombia and W Ecuador, and lower temperate zone, where once to 3400 m in Colombia.

**Food and Feeding.** Diet comprises arthropods, but details not known. Usually encountered singly or in pairs among mixed-species flocks (over 70% of all observations in one study); more common in larger flocks than in smaller ones, and often associated with Montane Foliage-gleaner (*Anabacerthia striaticollis*). At one Colombian site where resident, largely dropped out of flocks during Jan and, to lesser degree, late Sept. Forages primarily by hitching rapidly up relatively slim, moss-covered branches (often 7.5-15 cm diameter) from mid-levels to subcanopy, less frequently larger trunks closer to ground, frequently creeps along undersides of branches. Although uses all levels, from near ground to 20 m up, average foraging height seems to be c. 8 m, which was about two-thirds up most trees at one site; tends to exploit lower strata when in presence of flock. Branch-climbing behaviour results in foraging in more exposed situations than is typical of most cloudforest species. Most prey picked from surface, or taken from epiphytes, crevices, mosses or other substrates by digging or probing with slim bill; specializes on epiphyte-searching at some sites. Somewhat aggressive towards other dendrocolaptids, especially larger *Xiphorhynchus triangularis*.

**Breeding.** Season Apr-Jun in N Venezuela; apparently during dry seasons in Colombian Andes, where nests with eggs in early Aug (Huila) and with young in Jul (Valle), and fledglings and juveniles seen in Dec-Jan; otherwise, birds in breeding condition in Colombia in Apr-Jul in N (Perijá Mts), May-Aug in C Andes and Mar-Jun in W Andes. Presumably remains paired throughout year, as does *L. affinis*. Nest from low to high in tree, either in natural cavity or old hole of woodpecker (Picidae). One clutch comprised 3 white eggs, 27 × 22 mm; parental care presumably by both sexes.

**Movements.** Mostly resident, but some seasonal movement to lower elevations in Venezuela (especially during wet season).  
**Status and Conservation.** Not globally threatened. Uncommon to fairly common, and locally common, in humid forest almost throughout range, but apparently rare where present in montane dry forest in N Bolivia. This species' ability to exist in second-growth and edge environments suggests that it is only moderately sensitive to human disturbance.  
**Bibliography.** Anon. (1998a), Bangs (1930), Berlepsch & Stolzmann (1896), Berlepsch & Taczanowski (1884), Boesman (1998), Bond (1953), Chapman (1912, 1917, 1926), Chipley (1976), Cory & Hellmayr (1925), Fjeldså & Krabbe (1990), Garcia & da Silva (1997), Hellmayr (1920), Hilty (2003a), Hilty & Brown (1986), LeCroy & Sloss (2000), Lönnberg & Rendahl (1922), Menegaux & Hellmayr (1906a), Meyer de Schauensee (1945, 1950a, 1950b, 1952, 1964), Meyer de Schauensee & Phelps (1978), Miller (1963), Niethammer (1953, 1956), Parker & Bailey (1991), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Pearman (1993a), Phelps & Phelps (1963), Renssen (1985), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Schäfer & Phelps (1954), Selater & Salvin (1879), Stotz *et al.* (1996), Taczanowski (1882, 1884), Todd & Carriker (1922b), Willis (1986), Zimmer (1934c).

45. Streak-headed Woodcreeper  
*Lepidocolaptes souleyetii*

**French:** Grimpard de Souleyet      **Spanish:** Trepatorncos Cabecirrayado  
**German:** Lanzettstrichel-Baumsteiger  
**Other common names:** Souleyet's Woodcreeper

**Taxonomy.** *Dendrocolaptes souleyetii* Des Murs, 1849, Paita, Piura, north-west Peru. Appears to be closely related to *L. affinis*, *L. lacrymiger* and *L. albolineatus*. Races *lineaticeps*, *littoralis* and *uaireni* poorly differentiated from one another, whereas nominate and *esmeraldae* appear to represent extremes in a cline. Assessment of geographical variation complicated by marked individual and age-related variation in size, in width and extent of streaking above and below, in shade of upperparts, and in intensity of buff coloration on throat and underparts. Birds from SE Mexico to N Honduras often recognized as race *insignis*, said to differ from *compressus* in deeper buff throat and broader streaking both above and below, but neither character seems geographically related and considered better merged with latter; variation in Middle America most evident as cline of decreasing size from N to S. Seven subspecies recognized.

**Subspecies and Distribution.**  
*L. s. guerrerensis* van Rossem, 1939 - W Mexico (Sierra Madre del Sur, in Guerrero and SW Oaxaca).  
*L. s. compressus* (Cabanis, 1861) - lowlands on both slopes of Middle America from S Mexico (S Veracruz, SW Campeche, SW Chiapas) S to W Panama (E Chiriquí, W Bocas del Toro).  
*L. s. lineaticeps* (Lafresnaye, 1850) - C & E Panama (E from Canal Zone), N & E Colombia (except Santa Marta region) and W Venezuela (Táchira, W Mérida, extreme W Barinas).  
*L. s. littoralis* (Hartert & Goodson, 1917) - NW Colombia (Santa Marta region, Atlántico), N & C Venezuela (NW Zulia E to Sucre, S to Orinoco region), Guyana and extreme N Brazil (upper R Branco); also Trinidad.  
*L. s. uaireni* Phelps, Sr. & Phelps, Jr., 1950 - Known only from type locality on R Uairén, in extreme SE Venezuela (SE Bolívar).  
*L. s. esmeraldae* Chapman, 1923 - SW Colombia (Nariño) and W Ecuador (S through most of El Oro).  
*L. s. souleyetii* (Des Murs, 1849) - SW Ecuador (S El Oro, Loja) and NW Peru (S to Lambayeque).

**Descriptive notes.** 17-22 cm; 22-34 g. Slim, medium-sized woodcreeper with relatively long tail and slim, moderately long, slightly decurved bill. Nominative race has face finely streaked whitish-buff and dark brown, neck more boldly streaked, contrasting whitish-buff supercilium and eyering; forehead, crown and nape dark brown boldly streaked whitish-buff, with long narrow streaks often continuing onto upper back; back and wing-coverts rufous-olive to cinnamon-brown; rump, remiges and tail cinnamon-rufous to rufous-chestnut; primaries edged brown, tipped dusky; throat whitish-buff to pale cinnamon contrasting with greyish-olive to buffy-brown underparts, the latter heavily streaked whitish-buff, each streak edged blackish; streaks on breast and sides broad and somewhat rounded at tip, those on belly and flanks narrower and more weakly edged, those on undertail-coverts much reduced; underwing-coverts ochraceous to pale cinnamon-buff; iris dark brown; bill light brown, flesh-coloured or pale greyish-horn, base of upper mandible usually darker, base of lower mandible whitish, bluish or flesh-coloured; legs and feet greyish-green, bluish-slate or brown. Distinguished from closely similar *L. albolineatus* by mostly pale bill, paler upperparts, streaked crown; from similar *L. affinis* and *L. lacrymiger* by streaked (not spotted) crown, less extensively buffy throat not bordered by dark malar stripe, streaking more extensive on back and broader on underparts. Species of *Xiphorhynchus* that are heavily streaked below are larger and stockier, have a heavier and straighter bill, and generally are less extensively streaked. Female may be slightly smaller than male. Juvenile is dusker overall, with streaking on lower breast and belly narrower, more indistinct, and usually more weakly margined, throat duller buff with streaked or scaled appearance, undertail-coverts pale cinnamon-buff, bill shorter and usually darker. Race *esmeraldae* is like nominate, but throat and streaking below are a deeper buff in colour, streaks with less pronounced dusky margins, bill shorter. Races *lineaticeps*, *littoralis* and *uaireni* are also similar to nominate, but with upper mandible dark brownish, streaks on crown and underparts narrower, lower throat finely streaked dusky, and rufous of rump, wings and tail darker; *littoralis* differs from *lineaticeps* mainly in its smaller size, but also on average paler and less rufescent above, lighter and more buffy below; *uaireni* is darker above and below than either *lineaticeps* or *littoralis*, with throat and streaking on both crown and underparts more whitish (less buffy), crown streaks narrower, streaks below with blacker margins; *compressus* is like *lineaticeps* but darker, with broader streaking above and below, with streaks on back more extensive and often with dark margins, throat pale buff to whitish, variable, streaking sometimes even broader and throat darker buff ("insignis"); *guerrerensis* is slightly larger and somewhat paler than *compressus* (lighter red above, greyer below). **Voice.** Song, given by both members of pair, a rapid musical trill of 1-5-3 seconds, comprising 25-30 notes, sometimes on same pitch, usually with downward inflection, "quee-hee-hee-hee-hee-hee-heh"; little or no geographical variation apparent. Calls include various additional trills or chirps, some slurred, others piercing and staccato; also plaintive "pyuu" and doubled "trrew, trrew".  
**Habitat.** Occupies a variety of lowland habitats, preferring more open situations than those inhabited by most dendrocolaptids. Primarily open woodland, deciduous and gallery forests, wooded

savanna, mangroves, arid scrub, plantations, second growth, forest edge, and even rural areas with scattered trees; less often, interior of humid evergreen forest, lower montane forest, oak (*Quercus*) woodland and, in N of range, pine (*Pinus*) savannas. Roosts alone in tree cavities: enters in near darkness, leaves at first light. Mostly lowlands below 1000 m; locally in small numbers in foothills, to 1800 m in lower subtropical zone. Elevational range overlaps slightly with that of *L. affinis* on Caribbean slope (but generally not on Pacific slope) of Central America, and with that of *L. lacrymiger* in W Ecuador.

**Food and Feeding.** Feeds largely on insects, spiders and other invertebrates. Stomach contents primarily termites (Isoptera), ants and beetles, but also a variety of other items including wasps and bees, various orthopterans, pentatomid bugs, eggs and larvae of various arthropods, caterpillars and small moths, spiders, small crabs, scorpions, millipedes (Diplopoda), and even small quantities of fruit pulp from *Bromelia pinguin* (Bromeliaceae). Most prey examined in one study were 5-15 mm in size, with some items slightly larger. Usually encountered singly or in pairs, sometimes in families during breeding season; occasionally associates with mixed-species flocks (present in just over 20% of flocks at one site in Venezuelan llanos); found rarely in same flocks as *L. affinis* near upper elevational limit (especially during non-breeding season). Forages on branches and trunks (occasionally cactus stalks at some sites), mostly from mid-levels to subcanopy, sometimes higher or lower. Hitches rapidly up trunks and branches, often using spiralling motion; sometimes on larger trunks near ground or branches in canopy, and frequently creeps along undersides of branches. Seemingly more active than many woodcreepers. Most prey gleaned from surface, or taken from bark crevices, mosses or other substrates by probing with slim bill or by flaking or prying off bark or moss to expose hidden prey; only rarely digs into or pecks on decaying wood.

**Breeding.** Birds in breeding condition from mid-Mar to mid-Aug throughout range, also in Oct in Colombia; inspecting nesting cavities from late Feb, carrying nest material to cavities early Mar to early Jun, laying in late Mar to mid-Jun (mostly Apr), young in nest after mid-Apr, and juveniles in Jul-Aug; sometimes two broods per season. Remains paired throughout year. Nest in cavity of living or dead tree near (but usually not in) forest, natural cavities preferred over old woodpecker (Picidae) holes, entrance usually relatively high, 5-25 m up, exceptionally to 3 m. floor of nest-chamber usually lined with small to sometimes quite large fragments of stiff bark, in Trinidad possibly also weed stems and plant down. Clutch 2 glossy white eggs, average 26 × 19 mm; both sexes incubate but apparently only female at night; in one study sessions during day lasted 5-72 minutes (average 16-37.5 minutes), with nest unattended for periods of 2-41 minutes (average 17-21 minutes); in all, eggs attended for 60-65% of time under observation; during incubation parents frequently return to nest with a bark flake, less often leave with one; incubation period apparently 15 days; nestlings often quite vocal, fed by both parents, chiefly with insects at a rate of 1-6-4 visits per hour at one nest, depending on age of chicks; nestling period 18-19 days; neither young nor parents return to nest after fledging. At one nest, adults driven off by female *Dendrocincla anabatina*, which incubated their eggs and raised one chick to fledging. May molt before breeding cycle is completed.

**Movements.** Resident throughout range. Territories apparently settled immediately following breeding season at some sites.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of range; in Central America more common on drier Pacific slope than on humid Caribbean slope, and quite scarce at upper limit of elevational range. A widespread habitat generalist; its preference for second-growth, edge and other human-altered environments reveals a sensitivity to human disturbance that is lower than that of most woodcreepers.

46. Scaled Woodcreeper  
*Lepidocolaptes squamatus*

**French:** Grimpard écaillé      **German:** Fleckenbauch-Baumsteiger      **Spanish:** Trepatorncos Escamado

**Taxonomy.** *Dendrocolaptes squamatus* M. H. K. Lichtenstein, 1822, State of São Paulo, Brazil. Sister-species to *L. falcinellus*; previously regarded as conspecific, but three plumage characters (crown pattern, and coloration of back and of tail) and measurements differ significantly between populations on opposite sides of R Paraíba do Sul, in N São Paulo. Genetic distance between nominate race and *wagleri* relatively small, and one specimen has a blending of characters, these together suggesting that one biological species is involved. Two subspecies recognized.

**Subspecies and Distribution.**  
*L. s. wagleri* (Spix, 1824) - NE Brazil W of R São Francisco (S Piauí, W Bahia, N Minas Gerais).  
*L. s. squamatus* (M. H. K. Lichtenstein, 1822) - E & SE Brazil, S & E of R São Francisco, from C Bahia and Minas Gerais S to N bank of R Paraíba do Sul (N São Paulo).

**Descriptive notes.** 19 cm; 27 g (*wagleri*). Slim, medium-sized woodcreeper with slim, decurved bill. Nominative race has side of head dusky with whitish streaking, whitish supercilium often weak and broken; dark brown forehead and crown, the feathers each with buffy shaft spot (producing lightly spotted appearance that does not continue onto back); bright reddish-brown back, and cinnamon-rufous rump, wings and tail; whitish throat contrasts conspicuously with breast and belly, both of which are dusky brown with boldly black-edged whitish streaks; iris reddish-brown to brown; bill horn-coloured to mostly pinkish, upper mandible darker; legs and feet olive-grey to blackish. Confusion most likely with smaller *X. fuscus*, which is more buffy in face and below, has streaking on underparts more blurry (lacking crisp, black borders), and a more prominently streaked back. Distinguished from very similar *L. falcinellus* (nowhere sympatric) by weaker supercilium, weaker and less extensive crown streaking, whiter underparts, paler crown and upperparts.

Male has slightly longer wings and tail than female. Juvenile undescribed. Race *wagleri* is slightly smaller than nominate, brighter cinnamon-rufous above with minimal contrast between crown and back, crown spotting reduced to weak shaft streaks, underparts more brownish with less conspicuous dark borders to streaks. **Voice.** Song of nominate a slurred “peédeedir” or 1-2 “chip” notes followed by short series of loud, descending “cheew, cheew, cheeer” whistles, all in c. 2 seconds. Call a single rendition of the slurred note, described as a sharp, slurred “BEEarr” or “pyeer” that is often doubled. At least some calls and possibly song of *wagleri* similar to nominate.

**Habitat.** Nominata race occurs primarily in humid and semi-humid Atlantic Forest; most common in montane evergreen forest and lowland rainforest on Atlantic slope, less so in gallery forest along W fringe of range. Race *wagleri* occupies a drier region, where forest locally distributed; largely restricted to semi-deciduous and deciduous woodland, wooded *caatinga* and gallery forest, where most leaves lost during dry season. Frequents interior of mature forest, older second growth and forest edge. Mostly upper tropical zone, but from lowlands to 1600 m, occasionally to 2000 m or more.

**Food and Feeding.** Diet poorly known; presumably arthropods based on contents of two stomachs. Single birds, occasionally pairs, often encountered in mixed-species flocks, but tends to drop out of flocks during breeding season. Forages primarily while hitching up trunks and, especially, along slim branches, from mid-levels to canopy, less frequently closer to ground.

**Breeding.** Birds in breeding condition taken in Oct in Rio de Janeiro. Noted as nesting in buildings, as well as in more natural situations. No further information.

**Movements.** Apparently resident, but less conspicuous during breeding season.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common in humid forest at all elevations in S part of range, but scarce in lowlands to N; race *wagleri* more local in occurrence. Occurs in Cavernas do Peruagu National Park, in Minas Gerais, and in Augusto Ruschi Biological Reserve, in Espírito Santo. Requires relatively intact forest, and thus highly sensitive to human disturbance. This especially true within range of *wagleri*, where loss of forest through illegal fires, and through cutting for charcoal and agricultural development, represents a significant and continuing threat. Although *wagleri* is more common than globally threatened *Xiphocolaptes falcirostris*, it occupies habitats subject to same threats as those harbouring that species. Several recently created reserves in region may protect some populations.

**Bibliography.** Berlepsch & Ihering (1885), Brooke (1983), Cory & Hellmayr (1925), Davis (1945, 1946), Dunning (1993), Ferreira de Vasconcelos & Melo-Júnior (2001), Garcia & da Silva (1997), Goerck (1999a), Hellmayr (1929b), Ihering (1898), Kirwan *et al.* (2001), Meyer de Schauensee (1966), Mitchell (1957), Monteiro & Mattos (1984), Oniki (1980), Parker & Goerck (1997), Parrini *et al.* (1999), Pelzelin (1868-1871), Pinto (1978), Reiser (1926), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993), da Silva (1995b, 1996), da Silva & Straube (1996), Silveira (1998), Stotz (1993), Stotz *et al.* (1996), Willis & Oniki (1991).

## 47. Scalloped Woodcreeper

### *Lepidocolaptes falcinellus*

**French:** Grimpur festonné **Spanish:** Trepatroncos Festoneado  
**German:** Dunkelkappen-Baumsteiger

**Taxonomy.** *Thripobrotus falcinellus* Cabanis and Heine, 1859, Montevideo and Buenos Aires; error = probably São Paulo, Brazil.

Sister-species to *L. squamatus*; previously regarded as conspecific, but three plumage characters (crown pattern, and coloration of back and of tail) and measurements differ significantly between populations on opposite sides of R Paraíba do Sul, in N São Paulo; the depression associated with this river also represents a boundary for several other well-marked taxa. Monotypic.

**Distribution.** S Brazil from N São Paulo (S bank of R Paraíba do Sul) S to S Rio Grande do Sul, also adjacent SE Paraguay (Alto Paraná), NE Argentina (Misiones, NE Corrientes) and NE Uruguay.

**Descriptive notes.** 17-20 cm; 26-30 g. Medium-sized woodcreeper with relatively long, decurved bill. Adult has lores, face and bold supercilium creamy white, the last standing out conspicuously against blackish mottling of face; crown and nape dusky to dull black boldly spotted with rich buff (often continuing indistinctly as streaks onto upper back), contrasting sharply with olive-brown to cinnamon-brown back and wing-coverts, and rufous-chestnut rump and tail; outer webs of remiges brown, inner webs chestnut, tips of primaries blackish-brown; throat whitish; underparts olive, extensively and broadly streaked buff, each streak edged brown

to blackish (producing “scaly” pattern); underwing-coverts cinnamon; iris brown; upper mandible grey, light brown or pinkish (base often darker), lower mandible creamy white to light brown; legs greenish-grey to greenish-brown. Distinguished from closely similar *L. squamatus* by darker crown, darker and more chestnut tail, more conspicuous whitish supercilium, streaks on crown and underparts deeper buff, crown streaks also significantly broader. Also similar to *X. fuscus*, but larger, pale regions are more whitish, streaking on underparts has crisp blackish borders, and back is virtually unmarked. Female has slightly longer bill than male. Juvenile undescribed. **Voice.** Call a somewhat slurred rattle, described as “pit, eu-u-u”, “pee-u-u-u” or “peekku”, somewhat flatter in quality and more rattle-like than comparable calls of *L. squamatus*; lacks bubbling quality of *L. angustirostris*.

**Habitat.** Occurs in humid Atlantic Forest from lowlands into mountains; also in drier Planalto Forest in W part of range. Mostly montane evergreen forest and rainforest on Atlantic slope; also *Araucaria* forest in S of range and, less frequently, semi-deciduous forest in SW. Frequents interior of mature forest, older second growth and forest edge. Primarily upper tropical zone from lowlands to 1600 m, rarely to 2000 m.

**Food and Feeding.** Details of diet not known; presumably arthropods. Generally singly or in pairs, often in association with mixed-species flocks; present in nearly 10% of all flocks encountered at Atlantic Forest site in S São Paulo. Forages chiefly along trunks and branches from mid-levels to canopy, less frequently in understorey; sometimes creeps along undersides of horizontal branches. Most prey taken from epiphytes or bromeliads, bark crevices, mosses or other surfaces, but has been seen to sally to take aerial prey.

**Breeding.** In S of range (Rio Grande do Sul), birds in breeding condition from early Nov to early Dec, in non-breeding condition in early Mar, and possibly nesting in mid-Dec. Nest apparently in hole in tree; seen repeatedly to carry white objects to cavity 4 m up in a snag 8 m tall. Clutch 3 eggs, average 25 × 19 mm. Nothing more described of nest or other aspects of breeding biology.

**Movements.** Apparently resident throughout range.

**Status and Conservation.** Not globally threatened. Uncommon at some sites, but generally fairly common to common in humid foothill forest in core of range; possibly less common in lowlands and at W edge of range. Occurs in Itatiaia and Aparados da Serra National Parks, in Brazil, Ybicui National Park, in Paraguay, and Iguazú National Park, in Argentina. Generally believed to be highly sensitive to human disturbance; nevertheless, is able to exist in moderate numbers in older second growth and even relatively small forest fragments in S Brazil.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos & Graf (1993), dos Anjos *et al.* (1997), Azpiroz (2001), Belton (1984, 2001), Bencke & Kindel (1999), Berlepsch & Ihering (1885), Cory & Hellmayr (1925), Esteban (1948), Garcia & da Silva (1997), Höfling & Lencioni (1992), Ihering (1898), Laubmann (1940), Machado (1999), Mauricio & Dias (2001), Narosky & Yzurieta (1993), Narosky *et al.* (1983), Oniki (1981), Parker & Goerck (1997), de la Peña (1988), de la Peña & Rumboll (1998), Pinto (1978), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993), da Silva & Straube (1996), Stotz *et al.* (1996), Willis & Oniki (1981b).

PLATE 38

inches 3  
cm 8

## Genus *CAMPYLORHAMPHUS*

W. Berton, 1901

### 48. Greater Scythebill

#### *Campylorhamphus pucherani*

**French:** Grimpard de Pucheran

**Spanish:** Picoguadña Grande

**German:** Wangenstreif-Sensenschabel

**Taxonomy.** *Xiphorhynchus Pucherani* Des Murs, 1849, "Santa Fe de Bogotá", Colombia. Relationships uncertain; morphologically distinctive within genus. Variation in size, shade of rufous on upperparts, and extent of streaking on back and belly apparently individual and not geographically related. Monotypic.

**Distribution.** Locally in Andes from SW & C Colombia (in W mostly W slope in Valle and Cauca, also upper Magdalena Valley in W Huila, and along E Andean slopes S from Boyaca) S on W slope to NW Ecuador (S to Pichincha) and along E slope to SE Peru (S to Cuzco).

**Descriptive notes.** 24-30 cm; 63-78 g. Largest and heaviest-bodied scythebill, with bill stouter, shorter and not so deeply curved as that of congeners. Adult is dull rufous-brown to chestnut above, slightly darker on crown, and dark rufous-chestnut on rump, wings and tail; crown and nape with narrow buff streaks that sometimes extend to upper back; blackish-brown auriculars conspicuously framed by whitish supercilium and even bolder moustachial stripe; underparts rufous-brown to chestnut, with indistinct rusty-buff to greyish streaks on throat and breast, and sometimes upper belly; iris dark brown; bill dull pinkish-

horn to creamy grey, blackish base of culmen; legs and feet brownish-grey to dark brown. Differs from congeners especially in larger size, more boldly marked face. Sexes similar. Juvenile is more rufescent than adult, head, back and underparts with coarse, but poorly defined, buff streaking. Voice. Rarely heard. An alternating series of twitters and nasal "ik" notes, also described as "ee-ee-ee-ee-énh", and a more forceful and upward-inflected "oo-eeek" reminiscent of song of Ruddy Foilage-gleaner (*Automolus rubiginosus*); vocalizations unlike those of all congeners.

**Habitat.** One of few truly montane dendrocolaptids, occurring in variety of humid forest types from subtropical (rarely upper tropical) to lower temperate zones. Centre of abundance in mid-montane forest, where it frequents humid montane evergreen forest, cloudforest and elfin forest; at least occasionally outside forest, sometimes at forest edge, and has been found among banana trees. Primarily middle elevations of Andean slopes, 2000-2800 m; sometimes down to 900 m or up to 3250 m.

**Food and Feeding.** Diet poorly known, presumably mainly arthropods. One stomach contained small weevils, said to be common in banana trees on which bird was foraging. Only rarely encountered, then usually solitary, sometimes in large mixed-species flocks. Appears to forage largely in lower and middle strata of forest, often 1-5 m up, where it works moss-covered branches, tree-ferns, and trunks of larger trees. Hitches up trunks and branches; gleans prey from bark surface, or probes into mosses and crevices in bark.

**Breeding.** Almost unknown. Fledglings in Oct in E Ecuador; birds in Jul in Peru were in non-breeding condition and with partly ossified skull. No further information on nest, eggs or other aspects of breeding biology.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Also included in preliminary "blue list" of species at risk in Colombia. A moderate priority for future research. The most poorly known member of genus. Although linear range relatively extensive, occurs in a narrow elevational belt, and apparently quite rare and very local throughout range. Believed to be highly sensitive to human disturbance in a region where habitat loss is extensive and continuing, if not accelerating.

**Bibliography.** Chapman (1926), Collar *et al.* (1994), Dunning (1993), Fjeldså & Krabbe (1990), Goodfellow (1902), Gyldestolpe (1941a), Hilty (1985), Hilty & Brown (1986), Krabbe *et al.* (1997), Mazar Barnett & Kirwan (2002a), Meyer de Schauensee (1964), Negret (2001), Parker *et al.* (1982), Pitman *et al.* (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rodner *et al.* (2000), Salaman, Stiles *et al.* (2002), Stattersfield & Capper (2000), Stotz *et al.* (1996).

### 49. Black-billed Scythebill

#### *Campylorhamphus falcularius*

**French:** Grimpard à bec en faux

**Spanish:** Picoguadña Piquinegro

**German:** Dunkelappen-Sensenschabel

**Taxonomy.** *Dendrocopus Falcularius* Vieillot, 1822, Serra dos Órgãos, Rio de Janeiro, Brazil. Sometimes thought to form a superspecies with *C. trochilirostris*; regarded by some authors as conspecific, an arrangement disputed by most. Close relationship with *C. procurvoides* also suggested. Monotypic.

**Distribution.** SE Brazil from C Bahia (Chapada Diamantina) S to N Rio Grande do Sul, also adjacent E Paraguay (Alto Paraná, Itapúa) and NE Argentina (Misiones, NE Corrientes).

**Descriptive notes.** 24-28 cm, 37-42 g. Slim, medium-sized woodcreeper with exceptionally long, very slim, strongly decurved bill (curvature individually variable). Adult has face finely streaked clear buff and blackish, neck more coarsely streaked with similar colours, supercilium narrow and buffy-white; blackish crown and nape finely streaked whitish to ochre, with fine streaks extending onto upper back; back, wing-coverts and rump brownish to olive-brown, but wings, uppertail-coverts and tail rufous-chestnut; primaries tipped blackish-brown, rectrices with blackish shafts; whitish throat feathers edged dark olive-brown, resulting in streaked pattern; pale brown

to olive-brown below, more cinnamon on undertail-coverts, breast with narrow, indistinct whitish to creamy buff streaks that virtually disappear on belly, but appear again weakly on undertail-coverts; underwing-coverts rosy cinnamon; iris dark cinnamon-brown; bill brownish-black to black; legs and feet yellowish-green, greenish-grey or dark grey; populations from interior SE and S Brazil more rufescent overall, with crown somewhat browner, bill slightly paler. Differs most conspicuously from *C. trochilirostris* in dusky to black bill, more olive coloration above, with rufous of uppertail-coverts not extending over rump. Sexes similar. Juvenile resembles adult, but legs brown, bill shorter. VOICE. Song 3-5-4-5 seconds long, a series of 8-15 somewhat raspy or slurred notes that generally descends, but rises slightly at end, "bjeet, bjeet, bjeet, bjeet, bjeet, bjeet" or "jreet, jreet, jreet, jreet, jree-jree-jree-jree". Alarm a strident "spieh", sometimes doubled or tripled.

**Habitat.** Semi-deciduous and humid Atlantic Forest in mountains, less frequently lowlands, but also follows peninsulas and fragments of forest a short distance into somewhat drier habitats, including both *caatinga* and *cerrado*. Frequents mature evergreen forest and cloudforest, older second growth and edges; closely associated with thickets of *Guadua* bamboo. Lowlands and foothills to over 1600 m; frequents both tropical and subtropical zones but most common in upper tropical zone; in N of range largely restricted to mountains above 600 m.

**Food and Feeding.** Dietary details not known; believed to be insectivorous. Arthropods found in only stomach examined. Generally encountered alone, sometimes in pairs; regularly associates with mixed-species flocks that move through suitable habitat. Forages primarily along trunks, branches and bamboo stalks in undergrowth and mid-levels of forest, sometimes moving up into subcanopy. Moves among dense growth, probing deep into rectangular holes in hollow bamboo poles, cracks in trees, or bromeliads and other epiphytes. Prey items grasped between tips of long mandibles, before being swallowed as head jerked backwards.

**Breeding.** Nest with young ready to fly in late Sept in Paraguay (Alto Paraná); nest with eggs in late Nov and birds in non-breeding condition in Apr in NE Argentina. Nest a pile of relatively large (30-40 mm × 10-20 mm) wood chips or bark flakes, sometimes with layer of leaves on top, placed in tree cavity, in one case 1.5 m below entrance hole. Clutch 2 white eggs. Longevity records provided by two birds recaptured at site in C São Paulo, in Brazil, 5.5-6.5 years after banded.

**Movements.** Apparently resident throughout range.

**Status and Conservation.** Not globally threatened. Generally rare to locally uncommon in most of range, but fairly common at a few montane sites in SE Brazil; rare in Paraguay. Occurs in Itatiaia and Serra dos Órgãos National Parks and in Augusto Ruschi Biological Reserve, in Brazil. A forest-dependent species believed to be highly sensitive to human disturbance, which has been extensive throughout its range; present only in largest fragment surveyed in one study, and not recorded at all in most studies concentrating on forest fragments. One of relatively few woodcreepers for which monitoring of remaining populations has been recommended. An indicator species for both lowland and montane bamboo thickets, also for upper montane evergreen forest, all within Atlantic Forest region.

**Bibliography.** dos Anjos *et al.* (1997), Belton (1984), Berton (1901), Brooke (1983), Chapman (1889), Cory & Hellmayr (1925), Darrieu & Camperi (1990), Davis (1945, 1946), Dunning (1993), Esteban (1948), Ferreira de Vasconcelos & Melo-Júnior (2001), Fraga & Narosky (1985), Goerck (1999a), Hayes (1995), Ihering (1898), Lopes, L.E. *et al.* (2003), Lopes, O.S. *et al.* (1980), Machado (1999), Menges & Hellmayr (1906a), Meyer de Schauensee (1966), Narosky & Yzurieta (1993), Narosky *et al.* (1983), Olrog (1959a, 1979b), Oniki (1981), Parker & Goerck (1997), Parrini *et al.* (1999), de la Peña (1988), de la Peña & Rumboll (1998), Pinto (1978), Pinto & Camargo (1956), Reinert *et al.* (1996), Ridgely & Tudor (1994), Rodrigues *et al.* (1994), do Rosário (1996), Scott & Brooke (1985), Short (1975), Sick (1993), Sillett *et al.* (1997), da Silva (1996), Stotz *et al.* (1996), Teixeira, Otsch *et al.* (1993), Willis (1979b), Willis & Oniki (1991).

### 50. Curve-billed Scythebill

#### *Campylorhamphus procurvoides*

**French:** Grimpard à courbe **German:** Dunkler Sensenschabel **Spanish:** Picoguadña Amazónico

**Taxonomy.** *Xiphorhynchus procurvoides* Lafresnaye, 1850, "Cayenne".

Suggested as sister-species of *C. trochilirostris*, with relationships among some taxa in group unclear. Races form two groups, differing both vocally and morphologically: N "*procurvoides* group" (including poorly differentiated *sanus* and S "*multistriatus* group" (with *probat* and similar *successor*). Birds from SE Amazonia (*multistriatus*) are morphologically intermediate between *C. trochilirostris* and nominate of present species, and members of entire "*multistriatus* group" are vocally more similar to *C. trochilirostris*. Assessment of geographic variation complicated by marked individual variation in overall coloration, and extent and width of streaking on both back and underparts. Specimens from islands in lower Amazon R (near Obidos, Brazil) have been attributed to *successor*, but this is unlikely on grounds of both ecology and biogeography. Five subspecies recognized.

**Subspecies and Distribution.**

*C. p. sanus* J. T. Zimmer, 1934 - NW Amazonia, from SE Colombia (W Meta, W Caquetá), NE Ecuador (Sucumbios) and extreme NE Peru E to extreme NW Brazil (upper R Negro), S & E Venezuela (S Amazonas, NE Bolívar; sight record from Monagas) and N Guyana.

*C. p. procurvoides* (Lafresnaye, 1850) - NE Amazonia, in Surinam, French Guiana and Brazil N of Amazon (lower R Negro E to Amapá).

*C. p. successor* Todd, 1948 - SW Amazonia, S of Amazon in W Brazil from N Acre E to R Madeira; also reported from river islands in lower Amazon R in Pará (near Obidos).

*C. p. probatus* J. T. Zimmer, 1934 - SC Amazonian Brazil, S of Amazon, between R Madeira and R Tapajós, S to C Rondônia and NW Mato Grosso.

*C. p. multistriatus* (Sneath, 1907) - SE Amazonian Brazil, S of Amazon, from R Tapajós E to R Tocantins, S to NE Mato Grosso.

**Descriptive notes.** 22.5-25 cm; 30-40 g. Slim, medium-sized woodcreeper with exceptionally long, slim, strongly decurved bill. Nominate race has dark brown head and neck, olive-brown to reddish-brown wing-coverts and back, and contrasting rufous-chestnut rump, remiges and tail; fine whitish to buffy streaks on crown, face and nape, may extend narrowly and sparsely onto uppermost back;

streaks below arrow-shaped and lacking dark borders, throat scaly rather than streaked, darker and more olive (less rufescent) general coloration, strong contrast between brownish back and rufous rump, slightly smaller size and shorter legs, bill slightly darker and more deeply curved; race *multostriatus* even more similar to *C. trochilirostris* with streaking above and below just as bold, but bill much darker, more blackish, back and rump showing a marked contrast, and streaks below parrow to pointed tips. Female is slightly smaller than male. Juvenile undescribed. Race *samus* is distinctly smaller than nominate, more warmly coloured, with shorter and more strongly decurved bill, whiter throat and more streaked than scaled; *multostriatus* is quite different, with blackish head, dark rufous-brown back, darker chestnut rump and tail, whitish throat largely unmarked, streaking both above and below broader, that on upperparts black-edged and extending well down back, bill dark brown to reddish-chestnut with paler lower mandible; *probatas* and *successor* are both similar to *multostriatus*, but crown less blackish, back duller brown, throat duller and more obviously streaked (neither scaly like nominate nor unmarked like *multostriatus*), streaking both above and below usually narrower, less extensive, and with dark borders less distinct; *successor* differs from *probatas* in being both more rufescent and more heavily streaked above and below. Voice. Song, often given only in short bouts and mainly at dawn, is geographically variable. In nominate race an accelerating series 1.5-2.5 seconds long of 7-9 somewhat melancholy whistles on even pitch or falling slightly in both frequency and intensity before ending abruptly, "weeee, weé, wee, we, we, weew" or "kuweee, kuwee, kwee, wee-wee-we-we-we"; more musical and noticeably slower than that of *C. trochilirostris*. Song in Venezuelan (*samus*) begins as series of drawn-out whistles, rapidly accelerates into fast and relatively harsh rattle, "tweee, weee, weee, weee, weee, two-we-we-wi-wi-i-i-i-i-wik!" in S Amazonia (*probatas*) a rapid trill of 1.5-2 seconds and 15-25 notes, often (not always) with longer introductory note, "weeee, di, di-di-di-di-di-di-di-di-di-di-di-di-dew", more similar in quality to song of *C. trochilirostris* than to that of nominate, but trill usually ascends slightly before descending, and slows slightly at end. Most common call an explosive, relatively harsh "chit-di-dit".

**Food and Feeding.** Diet largely, if not exclusively, arthropods; stomach contents included beetle parts, a scorpion, and unidentified insects. Found singly or in pairs, usually among mixed-species flocks of understorey and, less frequently, subcanopy; at one site in French Guiana, 85-92% of observations involved birds in flocks, remaining longer than 15 minutes in 40% of flocks encountered; also found to switch between neighbouring flocks. No apparent preference for flocks led by *Thamnomanes* antshrikes (although sample limited). Forages primarily while hitching along slim to medium-sized trunks, relatively vertical limbs, large vines or bamboo poles from understorey to subcanopy, especially at 5-15 m. Most prey either gleaned from surface of trunks or branches, or taken by probing with exceptionally long bill into hidden recesses of dead bamboo stalks, ends of broken twigs and stubs, bark crevices, bromeliads and other epiphytes, clusters of hanging dead branches, or among vine tangles.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Generally uncommon and patchily distributed in core of C Amazonian range, but fairly common at a few sites with extensive bamboo thickets in S Amazonia: rare to very rare along W edge of range in SE Colombia, E Ecuador and NE Peru. Found at relatively low densities; only 1.25-2 pairs/100 ha estimated at one site in French Guiana. Highly sensitive to habitat modification, requiring nearly continuous forest. Near Manaus (Brazil) numbers much reduced following fragmentation, disappearing completely from fragments of 1 ha, and numbers significantly reduced in fragments of 10 ha. Similarly, at a site in French Guiana, the species disappeared completely following selective logging, returning only 8-12 years later, and then in much lower numbers. Considered an indicator species for tropical lowland evergreen forest in N Amazonia, and for bamboo thickets in both N & S Amazonia.

### Subspecies and Distribution.

*C. t. brevipennis* Griscom, 1932 - C & E Panama (N Coclé and E Panamá E to Darién) and NW Colombia (Pacific coast S to N Chocó).

*C. l. venezuelensis* (Chapman, 1889) - locally in N Colombia from Córdoba E to Magdalena Valley (S to N Huila), Caribbean lowlands and E of E Andes (Norte de Santander S to W Meta), and N & C Venezuela (E to Sucre, S to R Orinoco; locally in NW & S Bolivar); reports from French Guiana apparently refer instead to *C. procurvoides*.

*C. t. thoracicus* (P. L. Sclater, 1860) - coast of SW Colombia (SW Nariño) and W Ecuador.

*C. t. zarumillanus* Stolzmann, 1926 - coast of extreme NW Peru (Tumbes, Piura).

*C. l. napensis* Chapman, 1925 - W Amazonia in E Ecuador and E Peru.

*C. t. notabilis* J. T. Zimmer, 1934 - W Amazonian Brazil S of Amazon, between lower R Purús and lower R Madeira.

*C. t. snethlageae* J. T. Zimmer, 1934 - C Amazonian Brazil, on both banks of Amazon from R Madeira F to R Tapajós, including islands in Amazon R.

*C. t. devius* J. T. Zimmer, 1934 - SW Amazonia in N Bolivia; populations in adjacent SE Peru & W Brazil (Acre, SW Amazonas) may represent this race.

*C. t. lafresnayanus* (d'Orbigny, 1847) - C South America in E Bolivia (Santa Cruz), SW Brazil (W Mato Grosso, W Mato Grosso do Sul, possibly farther E) and W Paraguay (S to R Pilcomayo).

*C. t. hellmayri* Laubmann, 1930 - SW Paraguay (Neembucú) and N Argentina (Salta, Formosa and W Corrientes, S to La Rioja, Santiago del Estero, N Santa Fe and Entre Ríos).

C. t. major Ridgway, 1911 - interior E & S Brazil, from Piauí and Ceará S to Minas Gerais and extreme W Paraná

*C. t. trochilirostris* (M. H. K. Lichtenstein, 1820) - coastal E Brazil from Pernambuco S to SE Bahia (Ilhéus).

**Descriptive notes.** 22–28 cm; 30–55 g. Slim, medium-sized woodpecker with very long, slim, strongly decurved bill. Nominative race has finely streaked face and neck, weakly defined supercilium; brownish-olive crown and nape darker than reddish olive-brown back, crown with elongate whitish to ochraceous spots narrowly edged blackish, these becoming narrower and more elongate on nape, and reduced to fine shaft streaks on upper back; brown of back blending into cinnamon-rufous rump; remiges rufous-chestnut, tail slightly darker, wing coverts heavily edged reddish olive-brown, secondaries lightly edged with similar

colour, tips of primaries dusky; chin and throat white, throat with fine brownish streaks; underparts brown, slightly lighter than above, breast heavily streaked with buff (lacking dark marginals), streaks becoming narrower and shorter on belly and disappearing on lower belly and undertail-coverts; underwing-coverts light cinnamon to ochraceous; iris dark brown to hazel; bill bright red or reddish-brown, often dusky at tip and towards base; legs and feet greyish-olive to dull pea-green. Differs from nominate group of *C. procurviroides* in weaker contrast between back and rump, more extensive streaking on upper back, streaks above and below broader to tip (not narrowing to fine arrow-like point), legs slightly longer, bill paler, redder and less strongly curved; even more similar to "multistriatus group" of *C. procurviroides*, which is also heavily streaked above, but retaining characters still separate the species, and bill of *multistriatus* is dark-brown to reddish-chestnut; *C. falcularius* is darker overall, with back more extensively olive and rufous limited to uppertail coverts, streaking below narrower and more limited, crown and bill blackish; *C. pusillus* is also darker and more olive overall, more narrowly streaked above and below, with crown blackish, and bill brownish (less reddish) and shorter. Female is slightly smaller than male. Juvenile resembles adult, but plumage less richly coloured, streaking less clearly defined and more ochraceous, bill markedly shorter and darker (dusky blackish basally, reddish-brown distally). Within "*trochilostriis* group", race *lafresnayanus* is larger and especially longer-billed than nominate, has underparts bright tawny-ochraceous, back brighter rufous (almost same color as rump, wings, tail); *hellmayri* is larger still, with longer and more robust bill; *major* is most similar to *lafresnayanus* but links it with nominate morphologically (and geographically) in having upperparts less rufous and bill much shorter; size and bill length similar to nominate, but overall coloration slightly paler, wings and tail more cinnamon or rufous, lower throat may be more boldly streaked. Within Amazonia, *race devius* is similar to *lafresnayanus* but with bill much shorter, plumage decidedly darker, and lower throat strongly washed with buff; *sneathlageae* is similar to *devius* but underparts darker and with rufescent tinge, streaks on crown narrower, and throat whiter; *notabilis* is similar to *sneathlageae* but overall coloration paler brown, and streaking above and below both broader and whiter. Despite its Amazonian distribution, race *nepensis* is most similar to *thoracicus* but bill more strongly decurved, crown browner (less black), dark borders of streaks narrower and less conspicuous. Members of "venezuelensis group" are longer-billed than nominate, also darker overall, throat buffier and streaked more extensively and more heavily, crown blackish instead of brown, back and underparts darker olive-brown, and rump, wings and tail deeper rufous-chestnut; race *brevipennis* is darker and slightly smaller than *venezuelensis*, but has a proportionately longer bill. Birds of "thoracicus group" are similar to *venezuelensis* in coloration but streaks above and below have distinct, black borders; *zarumillanus* is said to be larger than *thoracicus*, with bill longer, more weakly curved. Voice. Song highly variable, both geographically and motivationally. Variation best documented in Venezuela, where two different songs may be given by same bird, one a rapid descending whinny of 10–25 somewhat musical notes lasting 2–2·5 seconds before ending with several slower notes, e.g., "we-he'he'he'he'-he'e'e'e'e'e'" or "tuwée-tuwée-toowa-tew-tew-tew-tew-tew-tew-tew-tew-", and the other (apparently given by agitated birds) a rapid staccato trill (30–35 notes, 2·2–5 seconds) sharply ascending, slowing slightly and sometimes doubled, "dedede'e'e'e'e'e'" or "stri'i'i'i'i'i'i'i'i'IKK!" (similar in quality and pattern to song of *Xiphorhynchus obsoletus*). In W Ecuador and NW Peru,

song is instead a descending and gradually slowing series of fewer whistled notes, "tuwee-tuweetoo-wa-tew-tew". In S of range a similar series of longer, clearer whistles that descend only slightly: in Brazilian Pantanal 13-15 notes are given in 2.5-3 seconds and described as "eep, eep, eep, eep, eep, eep, pee, pee, pee, pee, pee, pee, pee", in N Bolivia and N Argentina songs are similar in quality but possibly not in timing. When agitated, sometimes gives a descending series of loud, musical "chip" notes; when alarmed, often emits an explosive "chi-dik" that may be repeated.

**Habitat.** Occurs in a variety of wooded habitats, both in lowlands and adjacent foothills, but usually in relatively open situations. Frequents Chaco and other open woodlands, deciduous and gallery forests, *cerrado*, *caatinga*, forest islands in savanna, forest edge, second growth, and various other relatively scrubby habitats; some populations in humid evergreen forest in lowlands or premontane forest and cloud forest in foothills. In Amazonia, primarily seasonally flooded forest (especially *várzea*) and early-successional riverside cane (*Gynerium*), being replaced in adjacent *terra firme* forest by *C. procurviformis*; also in dense thickets of bamboo, where ecological separation from that species less clear. Mostly tropical lowlands and foothills to c. 1200 m; occasionally ranges into subtropical zone to 2100 m in Andean foothills and coastal cordilleras of N Venezuela.

**Food and Feeding.** Diet primarily arthropods and especially soft-bodied items such as spiders, but some vertebrate prey apparently taken. Stomach contents included various beetles, ants, flies, small Lepidoptera, cockroaches (Blattodea), millipedes (Diplopoda), parts of spiders, insect larvae, a small scorpion, a large cicada (Cicadidae), and tiny bones. Most prey for which size could be determined were relatively small, less than 20 mm, but some beetle larvae 18-25 mm. Larger items sometimes battered against tree trunks before being swallowed. Generally alone, occasionally in pairs, and often (but not always) with mixed-species flocks; present in 33% of flocks encountered at one site in Venezuelan llanos. Usually seen as it hitches up trunks and branches from upper undergrowth to subcanopy, sometimes higher or lower. At one site in SE Peru, occurred mainly in bamboo thickets, where foraging was concentrated 5-3 m above ground (about a quarter of way up 20-m canopy) and perches used had average diameter 8-3 cm; prey, however, were taken from slightly slimmer substrates averaging 6-3 cm; nearly 75% of foraging attempts were made on bamboo stalks (55-4% live stalks, 18-5% dead), with remaining 26% on other substrates. Forages primarily by probing holes and crevices in bark and bamboo poles, fallen logs, rotting wood, or clumps of moss, bromeliads or other epiphytes; in Peruvian study, over 90% of attacks on prey involved probing, with most of rest gleaning (but occasionally by prying off bits of substrate). Most prey taken from holes in bamboo poles made by, among others, various woodpeckers (Picidae). Amazon bamboo rat (*Dactylopsax dactylinus*) or Peruvian Recurvebill (*Simoxenops ucyalyae*) (46-8%), remaining substrates were bamboo nodes (19-4%) and internodes (8-1%), and non-bamboo stems (25-8%).

**Breeding.** Breeding in May-Jul in N Venezuela; nest with eggs in late Oct in Argentina (Santa Fe); immature in late Jan in Paraguayan Chaco; birds in breeding condition in Feb-Oct in Panama and N Colombia, and in Sept to mid-Nov in S Brazil (Mato Grosso do Sul, where moulting flight-feathers in May), N Bolivia, Paraguayan Chaco and N Argentina. Nest in cavity in tree or stump; one was located in hollow stump 1 m tall; another was 3-5 m up in a hollow *Gleditsia* tree, with lining of leaves and other herbaceous material from same tree. Clutch 2 smooth, white eggs, occasionally 1 or 3, size apparently varying, from 24 × 21 mm to 30 × 21 mm. A male found with a brood patch suggests extended pair-bond with parental care shared by both sexes.

**Movements.** Apparently resident and territorial throughout range.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common but locally distributed throughout most of range; quite scarce within limited region of Central America where it occurs, and scarce at upper end of elevational range. Densities at one site in SE Peru estimated at 17-6 territories/100 ha within stands of bamboo, but 8-5 territories/100 ha on site as a whole; another study in same region obtained comparable estimate of 9 territories/100 ha in early-successional growth along rivers. By contrast, much lower estimates for mature floodplain-forest, e.g. 0-5-1-4 pairs/100 ha, probably reflect patchy distribution of bamboo and presence of species only on small fraction of plot. At least some populations believed to be highly sensitive to human disturbance. Considered an indicator species for tropical lowland humid forest in Chocó lowlands of NW South America, and for bamboo thickets in both N & S Amazonia.

## 52. Brown-billed Scythebill

### *Campylorhamphus pusillus*

**French:** Grimpar à bec brun **German:** Brauner Sensenschnebel **Spanish:** Picoguadaña Andino

**Taxonomy.** *Xiphorhynchus pusillus* P. L. Sclater, 1860, in *Nova Grenada int.* = "Bogotá".

Central American races considered by some authors to represent a separate species "*C. borealis*". Assessment of patterns of geographical variation complicated by individual variation in general coloration and in extent of streaking. Races *borealis* and *olivaceus* poorly differentiated from one

another; variation upon which *tachirensis* and *guapiensis* based possibly individual rather than geographical. Five subspecies recognized.

#### **Subspecies and Distribution.**

*C. p. borealis* Carriker, 1910 - Costa Rica (Caribbean slope, also in SW on Pacific slope and adjacent lowlands) and W Panama (W Chiriqui, W Bocas del Toro).

*C. p. olivaceus* Griscom, 1927 - C & E Panama (Veraguas E to E Darién).

*C. p. tachirensis* Phelps, Sr. & Phelps, Jr., 1956 - Perijá Mts and extreme E Andes in NE Colombia and NW Venezuela (W Zulía, SW Táchira).

*C. p. pusillus* (P. L. Sclater, 1860) - N & C Andes on both slopes in Colombia (except extreme NE) and Ecuador, and on E slope in N Peru (S to Cajamarca and San Martín).

*C. p. guapiensis* Romero-Zambrano, 1980 - coastal lowlands of SW Colombia (Cauca).

**Descriptive notes.** 20-25 cm; 32-48 g. Slim, medium-sized woodcreeper with long, slim, strongly decurved bill. N nominate race has side of head and neck streaked blackish-brown and buff, supercilium buffy and inconspicuous; crown and nape dark brown, narrowly streaked deep buff (streaks extending sparsely onto upper back); back and wing-coverts deep reddish-brown, rump cinnamon-rufous, and wings and tail rufous-chestnut; primaries edged greyish-brown, tipped dusky; throat deep buff with dusky streaks; underparts dark brown to olive-brown, lower belly and undertail-coverts paler and often more rufescent; lower neck, breast

and upper belly narrowly streaked deep buff, undertail-coverts finely streaked buff; underwing-coverts cinnamon-buff to ochraceous; iris dark brown to reddish-brown; bill blackish-brown to brownish-horn, upper mandible dusky at base, lower mandible paler; legs and feet olive-green to blackish-brown. Distinguished from similar *C. trochilostrius* and *C. procurviformis* by slightly shorter and brownish bill, darker and more olive general coloration (blackish on head) and, from *C. trochilostrius*, also by less extensive, narrower streaking both above and below, and deeper buff throat and streaking. Sexes similar. Juvenile is darker and more olivaceous than adult, streaking above and below broader, less distinct, deeper buff in colour, bill markedly shorter and darker. Race *tachirensis* is similar to nominate but more olive, especially below; *guapiensis* is smaller, more brownish (less olive) overall than nominate, with ochraceous streaking limited to crown, nape, breast and upper belly; *borealis* is also similar but darker overall, more blackish on crown, more olive below, with deeper buff streaking narrower but more extensive (to both upper back and middle of belly), wings and tail deeper chestnut, upper mandible darker; race *olivaceus* is slightly smaller and even darker than *borealis*, with crown black, back deeper brown, underparts more olive. Voice. Song, given primarily at dawn and dusk, a rapid, complex and highly variable series of notes lasting 2-5-5 seconds, beginning with a soft, twittering trill that continues in background during a series of loud whistles that are usually descending (sometimes ascending) and somewhat quavering, e.g. "wheéwhipwhipwhipawéé, at-t-t-t-t-weeawéawéé" or "twe-weo-WEO-weo weo-we-we-we-we-we"; sometimes shortened to descending "whip aweé, aweé, aweé", and successive songs often connected by the soft "twe" or "we" notes of trill.

**Habitat.** Humid evergreen forest, primarily in hilly regions, locally in lowlands. Prefers interior and edge of wet, epiphyte-laden cloudforest at middle elevations, less frequently older second growth; once recorded in degraded dry forest in lowlands of W Ecuador during unusually wet conditions of El Niño season (then found sympatrically with *C. trochilostrius*). Chiefly in upper tropical and subtropical zones at 600-1700 m in S Central America, but generally at 1250-2000 m (2200 m at some sites and once to 2500 m) in N & C Andes; rare and local in tropical lowlands down to 200 m at various sites along Pacific slope, and exceptionally to sea-level in SW Colombia.

**Food and Feeding.** Arthropods, including variety of beetles, earwigs (Dermaptera), ants, insect eggs and larvae, and spiders. Stomach contents included mainly beetles, but also a spider and an unspecified orthopteran. Seen singly, occasionally 2 together, most often in association with mixed-species flocks, but present in only small percentage of flocks encountered at most sites; e.g. found in fewer than 6% of flocks followed during one study in N Costa Rica, but often remained with flock for extended period, generally more than 2 hours. Forages mainly while hitching along rugged trunks (often along underside) and vines from understorey to subcanopy, less frequently among fallen logs or in canopy; seems to avoid bare trunks and limbs. Most prey gleaned from surface of trunks or major branches, or taken by probing with exceptionally long bill into hidden recesses of bark crevices, moss tufts, bromeliads and other epiphytes, clusters of palm fruits or bases of palm fronds, or among vine tangles.

**Breeding.** Recently fledged juveniles in May-Jul in Costa Rica, and birds in breeding condition in May-Jun and late Dec in Colombia. Apparently forms extended pair-bond for breeding. No information on nest, eggs or other aspects.

**Movements.** Apparently resident throughout most of range; possibly an altitudinal migrant at some sites in N.

**Status and Conservation.** Not globally threatened. Generally rare to uncommon and local throughout its montane distribution; rarer and possibly even more local at edges of range in N Costa Rica and N Peru. Invariably rare wherever it occurs in the lowlands. Believed to be highly sensitive to human disturbance, requiring extensive tracts of unbroken forest. Considered locally at risk in Chocó of SW Colombia, where it is limited by lack of habitat. An indicator species for upper tropical montane evergreen forest in N Andes.

**Bibliography.** Anon. (1998a), Becker *et al.* (2000), Blake (1961), Buskirk (1976), Carriker (1910), Chapman (1889, 1917), Cory & Hellmayr (1925), Cuervo *et al.* (2003), Dunning (1993), Griscom (1927a), Hartman (1961), Hilty (1997, 2003a), Hilty & Brown (1986), Meyer de Schauensee (1945, 1950a, 1964, 1966), Meyer de Schauensee & Phelps (1978), Olivares (1958), Parker, Parker & Plenge (1982), Parker, Schulenberg *et al.* (1985), Phelps & Phelps (1956, 1963), Powell (1979), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1909, 1911), Robbins *et al.* (1985), Rodner *et al.* (2000), Romero-Zambrano (1980), Salaman (1994), Salaman, Stiles *et al.* (2002), Salvin (1870), Skutch (1962), Slud (1964), Stiles (1983b, 1985), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972).

## Class AVES

## Order PASSERIFORMES

## Suborder FURNARI

## Family THAMNOPHILIDAE (TYPICAL ANTBIRDS)

- Small to medium-large birds, most with shortish wings, strong legs and feet, many with short tail but some with long graduated tail, proportionately large bill, some with hooked bill; plumage soft, generally not bright, but many with bright or white patch on back.
- 7.5-34 cm.

- Neotropical Region.
- Forest and woodland.
- 45 genera, 209 species, 516 taxa.
- 25 species threatened; none extinct since 1600.

## Systematics

Morphological studies carried out in the middle of the twentieth century demonstrated that the Thamnophilidae are a well-defined lineage, and this is supported by recent molecular analyses. With regard to relationships within the family, however, taxonomic confusion is found at all levels. Recent studies have indicated that some currently accepted subspecies are simply points on clines of plumage variation, while others appear to represent unrecognized species. Many species complexes remain ill-defined, and, although some genera comprise clearly related species, others are being shown to be polyphyletic. Relationships among the genera are uncertain, and undoubtedly there are a number of errors in the way in which the current taxonomic sequence reflects evolutionary relationships within the family.

The current systematic order for the Thamnophilidae was promulgated over 150 years ago, when fewer than 100 species were known, and the sequence has remained essentially the same since then. A revision based on comprehensive phylogenetic analysis of the family and using modern techniques remains to be accomplished. Consequently, it seems prudent for the time being to maintain largely the traditional sequence and definitions of genera and species of the Thamnophilidae as reflected in the checklist of J. L. Peters, published in 1951. In a few cases, however, rearrangement of genera and the elevation of certain subspecies to species status have received widespread acceptance following publication of peer-reviewed analysis.

Early pioneers confused antbirds with Eastern Hemisphere species, because of a resemblance between the two in physical characteristics. For example, the heavy bill and hefty look of certain antbirds resembled those of Old World shrikes (Laniidae), hence the common name of "antshrike" for such thamnophilid species (see Morphological Aspects). In 1847, the German anatomist J. Müller discovered that the syrinx of birds in a number of New World families, including the antbirds, differed substantially from that of what were then presumed to be their Old World relatives, and a more satisfactory picture could be drawn. Shortly thereafter, on the basis of Müller's work and adding considerations of external morphology, J. Cabanis and H. Burmeister published the first "modern" arrangements of the antbirds. Building on this work, P. L. Sclater and his colleagues began, in the mid-1850s, to publish a series of papers describing new species and proposing relationships, which culminated in 1890 with an arrangement in the *Catalogue of the birds in the collection of the*

*British Museum*. Sclater's taxonomic arrangement of the antbirds, which included both "typical antbirds" and "ground-antbirds", was based on external morphology, primarily on characteristics of the bill and tarsi but also on overall size, length of tail, and presence or absence of feathers around the eye. R. Ridgway's 1911 publication *Birds of North and Middle America* and C. E. Hellmayr's 1924 *Catalogue of birds of the Americas* modified some portions of Sclater's sequence, but the essence of Sclater's arrangement remains standing today with just a few prominent exceptions, most notably the separation of the typical antbirds and the ground-antbirds into two families.

In all these early classifications, typical antbirds were considered a subfamily, Thamnophilinae, and were placed in the family Formicariidae, along with the ground-antbirds, then treated as the subfamily Formicariinae. In the 1960s, anatomical differences between the two groups were noted. An initial study by M. A. Heimerdinger and P. L. Ames revealed differences in the shape of the sternum, following which, and on the basis of several features of the syrinx, Ames found that the "Formicariidae" fell into two structurally divergent groups which he called "typical antbirds" and "ground-antbirds". Then, in the latter part of the century, apparent confirmation of differences between the two antbird groups emerged in molecular studies. Prominent among these were the DNA-DNA hybridization data of C. G. Sibley and J. E. Ahlquist, which led to those authors' recommendation that typical antbirds should be treated as a separate family from the ground-antbirds. Analytical reviews of those data and other molecular studies have constantly supported that conclusion. Today, it is widely accepted that the typical antbirds and the ground-antbirds should be recognized as distinct families, the Thamnophilidae and the Formicariidae, respectively. Some molecular evidence, which needs to be verified, suggests that the two families may not even be each other's closest relatives. In the following text, the simple term "antbirds" encompasses only typical antbirds of the family Thamnophilidae.

Relationships within the Thamnophilidae remain unclear, and, as noted above, their current taxonomic treatment rests entirely on morphology, essentially external features, especially on characters obtained from examination of bills and legs. Other types of information are now becoming increasingly available, enabling the reassessment of relationships among species. Of the new methods and data, few would argue that molecular studies offer the greatest potential. To date, however, such studies have focused on a limited number of antbird species. The two most

extensive molecular studies, the DNA-DNA work of Sibley and Ahlquist and the protein-electrophoresis study of antwrens by S. J. Hackett and K. V. Rosenberg, have been used repeatedly in the following account, where they are referred to simply as "DNA-DNA" and "protein-electrophoresis" studies.

The use of nest architecture in phylogenetic studies, as exemplified most recently by the study of the Neotropical ovenbirds (Furnariidae) by K. Zyskowski and R. O. Prum, has not yet been undertaken for the antbirds. Although differences among the latter are not so dramatic as in the Furnariidae, the architecture of thamnophilid nests appears to have some value in systematic studies (also see Breeding).

Behavioural information also offers potential characters for phylogenetic analysis, and for antbirds none has received so much attention as have body movements, such as tail-pounding or wing-flicking (see General Habits), the relevance of which to a reconstruction of antbird phylogeny has been an interest in the work of E. O. Willis over almost the past forty years. Other potentially relevant aspects of behaviour, such as intraspecific displays, are now being recorded on videotape. Although scientists have started to use characters derived from antbird songs and calls as a means of defining species limits (see Voice), the application of these characters above the species level is less clear. Some vocal characteristics do appear to be common to members of apparently related taxa. Examples of vocal characteristics with possible value in phylogenetic studies include differences between species

groups in the constancy of male and female songs, in temporal relationships of response between male and female songs in duetting, in the occurrence of more than one type of intense, or loud, multi-noted song in species' repertoires, and in the structure of calls and rattles (see Voice).

Although none of these characteristics has been applied comprehensively to the family, information obtained to date, including preliminary and partial results of research, provides useful insights for continuing phylogenetic studies. The following paragraphs outline emerging data and analytical findings that point to evolutionary relationships among the 209 species of typical antbird, currently placed in 45 genera. Identifying these phylogenetic indicators helps fieldworkers to pinpoint gaps in our knowledge that may be of use in systematic studies, and offers systematists a menu of possible characters that might be included in a reconstruction of the evolution of the Thamnophilidae. Some of these traits, of course, may reflect convergence or parallel evolution, rather than being due to a common origin, but they are worth bearing in mind as being potential data for phylogenetic studies. The discussion below summarizes these insights, following the order of the current taxonomic sequence. For convenience, this is best divided into eight sections, based around the three large genera *Thamnophilus*, *Myrmotherula* and *Myrmeciza*.

The taxonomic sequence of Thamnophilidae begins with 16 antshrikes in eight genera. These precede the genus *Thamnophilus*, and are placed there primarily because of the strong, hooked bill,

Antbird taxonomy is in a state of flux. In-depth exploration, both of remote regions and of systematic relationships, has resulted in a cascade of new species during recent years.

Two such species, the **Ash-throated Antwren** and the **Ancient Antwren**, are named in honour of Ted Parker and Al Gentry, biologists at the head of their fields who died together in a tragic plane crash in the forests of South America.

The Ash-throated Antwren occupies a tiny geographical range in the Andean foothills of northern Peru; the Ancient Antwren occurs in white-sand forests of the nearby lowlands. They escaped detection until recently because of their canopy-living habits in localized habitats.

although that of one species in the group, the White-bearded Antshrike (*Biatas nigropectus*), is an exception. Molecular studies of the species in this segment of the sequence have not been undertaken, and little behavioural information is available to suggest relationships among them. Nest architecture is known for eight of the species, the nest of which is a suspended cup like that of *Thamnophilus*, except that the cup-nest of the Giant Antshrike (*Batara cinerea*), rather than being suspended, is supported by strong branches, this probably being a relatively recent adaptation to the species' large size. Characteristic body movements have been recorded for only four of the 16 species: horizontal tail wags (see General Habits) for the Black-throated Antshrike (*Frederickena viridis*) and the Undulated Antshrike (*Frederickena unduligera*), and vertical tail wags for the Collared Antshrike (*Sakesphorus bernardi*) and the Black-backed Antshrike (*Sakesphorus melanotus*), suggesting that these two pairs of species are not closely related. *Sakesphorus*, the largest genus in the group, may prove to be polyphyletic as presently defined; some of its six species are very similar to the *Thamnophilus* antshrikes in vocalizations and behaviour, and are likely to be integrated with the latter species in new groupings.

The 26 *Thamnophilus* species fit the image of prototypical antshrikes. Nests are known for 15 of the species, and are all cup-nests, typically suspended from the fork of a branch. Although DNA-DNA analysis indicates some genetic diversity within *Thamnophilus*, it provides no insights into relationships within the genus. Only a few species groups can be discerned with clarity on the basis of morphology, vocalizations and behaviour. Prominent among these is the group surrounding the Barred Antshrike (*Thamnophilus doliatus*), the type of the genus and with a range that extends from Mexico to Argentina, making it one of the two most widespread antbirds, the other being the Great Antshrike (*Taraba major*). Closely related to the Barred Antshrike are six species in which at least one sex has heavily barred plumage. All deliver similar "Loudsongs" (see Voice), an accelerating series of notes ending with an emphatic "caw". The Rufous-winged Antshrike (*Thamnophilus torquatus*) and the Rufous-capped Antshrike (*Thamnophilus ruficapillus*) are now considered part of this group on the basis of their similarly structured loudsongs and barred underparts; formerly, they were placed at the end of the *Thamnophilus* sequence on account of the smaller bill, and sometimes were put in a genus of their own, *Rhopochares*. A second species group consists of the Northern Slaty Antshrike (*Thamnophilus punctatus*) and its allies, and this offers an exam-

ple of the possible use of body movements in considering thamnophilid relationships. This complex was formerly considered to constitute a single species, but studies in the late 1990s by M. L. and P. R. Isler and B. M. Whitney revealed that it would be better treated as consisting of six species. Five of these, however, exhibit a rapid downward flicking or quivering of the tail as they move about, whereas the sixth, the Western Slaty Antshrike (*Thamnophilus atrinucha*), does not. This suggests that the latter may not be a member of this clade, a possibility strengthened by the fact that its rattle-calls (see Voice) are more similar to those of species outside the "slaty antshrike complex", in the genera *Thamnophilus* and *Sakesphorus*, than to those of species within it. Beyond these two species groups, obviously close relationships based on morphology, vocalizations and behaviour are found only in species pairs. These include the Black (*Thamnophilus nigriceps*) and Cocha Antshrikes (*Thamnophilus praecox*), the Blackish-grey (*Thamnophilus nigrocinereus*) and Castelnau's Antshrikes (*Thamnophilus cryptoleucus*), the White-shouldered

Since 1990, altogether 19 new species of thamnophilid have been recognized; nine of these were previously undescribed, and ten were elevated from subspecies or synonymized taxa. The Allpahuayo Antbird and the race centunculorum of the Northern Chestnut-tailed Antbird are examples of the former category, although the Northern Chestnut-tailed Antbird as a whole is an example of the latter! The two taxa pictured here were described in 2002, following fieldwork in the white-sand forests which occur near the city limits of Iquitos, northern Peru. Discoveries such as these not only highlight the importance of soil and geology as factors determining bird distributions, but serve as a reminder of how much remains to be discovered about birds in South America, even in relatively well-studied and heavily populated regions.

[Above: *Percnostola arenarum*.

Below: *Myrmeciza castanea centunculorum*. Allpahuayo-Mishana Reserved Zone, Loreto, Peru. Photos: José Álvarez Alonso]

(*Thamnophilus aethiops*) and Uniform Antshrikes (*Thamnophilus unicolor*), and the Plain-winged (*Thamnophilus schistaceus*) and Mouse-coloured Antshrikes (*Thamnophilus murinus*). The strengths of relationships between species in these pairs remain to be tested in molecular studies, and relationships among them and with other antshrikes are uncertain.

Following *Thamnophilus* and constituting the third section are 19 species of antshrike, antvireo and bushbird, a pot-pourri consisting mostly of fairly large species with a moderately strong, hooked bill or an unusual bill. The group is quite diverse and, although discussed in current taxonomic order, undoubtedly includes some species the roots of which lie elsewhere. The placement here of the Spot-winged Antshrike (*Pygiptila stellaris*), the sole member of its genus, will almost certainly prove to be an error, but this species' relationships are quite a mystery. According to DNA-DNA studies, it is as genetically distant from *Thamnophilus* as is any other thamnophilid genus examined; further, protein electrophoresis also distanced

*Pygiptila* from the antshrikes and indicated a relationship with the *Myrmotherula* antwrens of the "stipple-throated group", discussed below. The only described nest of the Spot-winged Antshrike bears some similarity to nests of *Thamnomanes* species; on the other hand, its foraging behaviour, whereby it scurries along branches and dives into dead-leaf clusters (see Food and Feeding), differs completely from that of *Thamnomanes* and may be unique in the family, while its vocalizations are quite distinctive. *Pygiptila* is followed by the three bushbirds, which have the most unusual, upturned, bill. They are placed in the two genera *Neotantes* and *Clytactantes*, which differ principally in the extent of the upswing of the bill, but their relationships to other genera are completely unclear. Their nests are undocumented, but their loudsongs and calls, known only for *Neotantes*, are quite distinct from those of *Thamnophilus* species. The foraging behaviour of the bushbirds, which burrow into stems and vines, also suggests that they are unlikely to be close relatives of *Thamnophilus* antshrikes, but little is known that would shed light on the alternatives.

The next three species, each in a monotypic genus, more clearly fit the image of an antshrike. Whitney and G. H. Rosenberg first identified similarities in the sally-strike foraging behaviour between the Pearly Antshrike (*Megastictus margaritatus*) and the Speckled Antshrike (*Xenornis setifrons*); the perch-glean foraging behaviour of the Russet Antshrike (*Thamnites anabatinus*), however, is dissimilar. All three species build suspended cup-nests, but the single nest described for the Pearly Antshrike was decorated with leaves, showing some similarity to nests of certain *Thamnomanes* antshrikes, also sally-strike foragers, while the Speckled Antshrike's nest is built entirely of rootlets, which appears to be unusual for an antbird.

The placement of *Dysithamnus*, the largest genus in the section, seems less problematic. DNA-DNA data and protein electrophoresis both suggest that the Plain Antvireo (*Dysithamnus mentalis*) belongs on the same branch of the family tree as *Thamnophilus*. The cup-nests of *Dysithamnus* antvireos are similar in shape to, although more "decorated" (see Breeding) than, those of *Thamnophilus* antshrikes, but the vocalizations, especially the calls, of the former are quite distinct. It also appears possible that *Dysithamnus* is polyphyletic; the White-streaked Antvireo (*Dysithamnus leucostictus*), Plumbeous Antvireo (*Dysithamnus plumbeus*) and Bicoloured Antvireo (*Dysithamnus occidentalis*) may prove to be not closely related to the remaining five species centred around the Plain Antvireo.

A decade ago the scientific name "*Thamnophilus punctatus*" was used to refer to the "Slaty Antshrike", a variable species that ranged from Belize to south-east Brazil.

Following a taxonomic review based on precise locality mapping and analysis of geographical variation, this taxon was subdivided into six different species.

The original scientific name now refers only to the Northern Slaty Antshrike of Central America and northern South America. The form west of the Andes is now called the **Western Slaty Antshrike**. Its vocal

uniqueness is corroborated by differences in morphology, such as the crown colour of females being concolorous with that of the mantle, and in behaviour, for example the fact that it does not quiver its tail like other slaty antshrikes. Indeed, current evidence suggests that it is not closely related to the other slaty antshrikes.

The male **Planalto Slaty-Antshrike** is morphologically and behaviourally much more similar to other slaty antshrikes, but it is more easily differentiated by song.

The "*Herpsilochmus pileatus* complex" is indeed complex! Formerly treated as a single species, it has now been split into four. The **Black-capped Antwren**, the English name previously applied to the whole complex, is now used only for the form *atricapilla*, pictured here. Somewhat confusingly, the oldest scientific name within the complex, *pileatus*, has been found to apply to a form only very recently distinguished as a separate taxon, and now labelled as the *Bahia Antwren*. In their own turn, the populations formerly considered most characteristic of the whole complex have undergone changes in both scientific and vernacular names, and are now known as the *Caatinga Antwren* (*H. sellowi*).

[*Herpsilochmus atricapilla*,  
Jujuy, Argentina.  
Photo: Darío Podestá]

Turning to the final genus in this third section of the sequence, the sally-strike foraging behaviour of the four *Thamnomanes* antshrikes, as T. S. Schulenberg pointed out, differs from that of species placed in *Thamnophilus* and *Dysithamnus*, and the special role of *Thamnomanes* as leaders of mixed-species flocks (see Food and Feeding) makes them an outstanding and distinct element in the lowland Amazonian avifauna. Furthermore, DNA-DNA analysis indicates that the Dusky-throated Antshrike (*Thamnomanes ardesiacus*) is not closely related to *Thamnophilus* species. Nest architecture within *Thamnomanes* is, however, conflicting, with the Dusky-throated Antshrike and, probably, the closely related Saturnine Antshrike (*Thamnomanes saturninus*) constructing suspended cups simply decorated with leaves, whereas the Cinereous (*Thamnomanes caesi*) and Bluish-slate Antshrikes (*Thamnomanes schistogynus*) build finely wrought cups into aerial masses of leaves supported against tree trunks or on branches in the understorey. The two pairs of species differ also in the extent of bristle-like feathers around the bill (see Morphological Aspects). If future molecular studies confirm that they are each other's closest relatives, it would provide the only known example of closely related thamnophilid species that differ substantially in their nest architecture.

*Myrmotherula* antwrens, with 35 species, form the largest genus of the Thamnophilidae and constitute the fourth segment of the sequence. Nevertheless, the protein-electrophoresis study of Hackett and Rosenberg indicated that the genus was, in fact, polyphyletic, a conclusion supported by a study undertaken by J. M. Bates and co-workers, using mitochondrial-DNA sequencing, and in a cladistic analysis of morphology and vocalizations by L. A. P. Gonzaga. Hackett and Rosenberg, who examined by far the greatest number of *Myrmotherula* species, proposed that, with a few exceptions, these antwrens fall into three lineages, their recommendations being consistent with the growing knowledge of the natural history of these birds. The three groups are the "streaked", the "stipple-throated" and the "grey" assemblages. The "stipple-throated antwrens", which the results of the molecular studies suggest as being rather distantly related to their supposed congeners, are specialists in dead-leaf foraging; they differ further from other *Myrmotherula* species in plumage, especially the spotted throat, and in nest architecture, vocalizations

and territorial displays. The assemblage clearly includes eight species, from the Brown-bellied Antwren (*Myrmotherula gutturalis*) to the Rufous-tailed Antwren (*Myrmotherula erythrura*) in the current taxonomic sequence. A ninth species, the Star-throated Antwren (*Myrmotherula gularis*), has been placed in this group because of its spotted throat, but its behaviour and nest architecture suggest otherwise.

In the protein-electrophoresis study, the "streaked antwrens", named for a conspicuous aspect of the plumage not found in other *Myrmotherula* species, clustered tightly together and were more clearly related to the "grey antwrens" than to the "stipple-throated assemblage". Their nests, obviously different from those of the latter, may also differ from those of the "grey antwrens", although more data are needed. Vocally, as shown by Isler and colleagues, members of the "streaked antwren assemblage" fall into four species groups, which also differ in morphology and ecology; the variety of ecological niches which they occupy includes forest canopy, riparian habitats and Andean foothill vegetation.

The "grey antwren assemblage" is the largest of the three, and with the greatest possibility of being polyphyletic. Within the group, the Plain-winged Antwren (*Myrmotherula behni*), the Yungas Antwren (*Myrmotherula grisea*), the Unicoloured Antwren (*Myrmotherula unicolor*) and the Alagoas Antwren (*Myrmotherula snowi*) appear to form a species group, termed the "Plain-winged *Myrmotherula* Group" by Whitney and J. F. Pacheco, its members being related by morphology and vocalizations. These four species occupy a variety of habitats in a large area extending from the Andean slopes to south-east Brazil. Two of them were included in Hackett and Rosenberg's study, which indicated that they were closely related. The same authors identified the Slaty Antwren (*Myrmotherula schisticolor*), the Rio Suno Antwren (*Myrmotherula sunensis*) and Salvadori's Antwren (*Myrmotherula minor*) as another species group, also on the basis of morphology and vocalizations. The six other species in this widespread assemblage are the White-flanked Antwren (*Myrmotherula axillaris*), Ihering's Antwren (*Myrmotherula iheringi*), the Rio de Janeiro Antwren (*Myrmotherula fluminensis*), the superspecies formed by the Long-winged (*Myrmotherula longipennis*) and Band-tailed Antwrens (*Myrmotherula urosticta*), and the Grey Antwren (*Myrmotherula menetriesii*). Molecular

In line with its English name, some of the races of the **Variable Antshrike** look dramatically different, as illustrated by these two males, both from the Brazilian Atlantic Forest. Even more different are the races melanochrous from Peru, with the male mostly black, and aspersiventer from Bolivia, with the underparts scalloped with white. The complex variation in plumage pattern throughout its range, along with its unusual geographical distribution, suggest that the Variable Antshrike is a prime candidate for systematic study. The traditionally accepted eight subspecies are provisionally retained in the current format until their vocalizations are properly analysed, or until parapatry without intergradation is proven between them. On a broader scale, the relationships of the Variable Antshrike within the genus *Thamnophilus* are uncertain. Although it has been thought to form a superspecies with the Amazonian Antshrike (*T. amazonicus*), such a relationship is not supported by the evidence of behaviour or vocalizations, and indeed is considered unlikely.

In the antbirds, sexual dimorphism is the rule. Although a minority of species are monomorphic, males tend towards combinations of grey, black and white, whereas females tend towards brown, rufous and buff. In species that show patterns of bars or spots on the upperwing-coverts, these are often formed by white tips or fringes of black or grey feathers in males, whereas females tend to have golden, buff or rufous tips or fringes of brown feathers. In species that are heavily barred black and white in males, this pattern is often partially replaced with chestnut or brown in females. This replacement of piebald plumage in males with browner plumage in females is common in members of the "Thamnophilus doliatus complex", such as the **Bar-crested Antshrike**. It is also seen in the **Great Antshrike**, which belongs to a related monospecific genus. Traditionally, this type of dichromatism in other families is explained by the greater role played by the female in incubation, and therefore her greater need to be camouflaged. As both sexes typically share incubation and brooding in antshrikes, the explanation is less convincing in this case. Striking plumage must be so important in male-male competition, or female mate-choice, that it pays to be a bright male even if the likelihood of nest predation is increased.

The antshrikes are a diverse assemblage of species, often without obvious taxonomic relationships. Most, like this **Fasciated Antshrike**,

are chunky birds, with large heads, strong legs and robust, hooked bills.

The latter feature can inflict a painful bite (as anyone who has handled an antshrike will attest!), and caused early naturalists to assume a relationship with the true shrikes (*Lanius*). Although this assumption proved incorrect, the English name has stuck. Many antshrikes live in tangled lower growth, but the Fasciated Antshrike usually frequents the mid-storey or subcanopy of forest. In this regard it is unique amongst the small subset of antbirds with bright red eyes.

VIREO]

studies indicate a close relationship among these species, which is supported by similarities in the calls of a number of them. The suspended cup-nests built by members of the "grey antwren assemblage" are similar to those of *Thamnophilus* antshrikes, although smaller in size.

The three remaining *Myrmotherula* antwrens do not fall clearly into any of the three assemblages. The Rufous-bellied Antwren (*Myrmotherula guttata*) and the Plain-throated Antwren (*Myrmotherula huxwelli*) form a superspecies, as indicated by plumage, vocalizations, behaviour and ecology. Molecular studies and nest architecture suggest that they are closest to the "grey antwrens", but their relationships remain uncertain. The Lead-colored Antwren (*Myrmotherula assimilis*), an inhabitant of river islands, is an outlier; in the protein-electrophoresis study, it was the closest of any of the *Myrmotherula* species to the *Thamnophilus* antshrikes.

Following *Myrmotherula* as the fifth section in the taxonomic sequence are 40 species in four well-defined polytypic genera, three of them termed "antwrens", and four monotypic genera. All are presumably placed near one another because of their mostly small size and a similarity in bill morphology. Two species in monotypic genera, the Banded Antbird (*Dichrozona cincta*) and the Stripe-backed Antbird (*Myrmorchilus strigilatus*), lead the list. The first of those shares certain plumage aspects and the architecture of its suspended cup-nest with three species currently placed in the genus *Hylophylax*, which comes near the end of the family sequence. The Stripe-backed Antbird's ground-foraging behaviour and nest, as well as the qualities of its vocalizations, suggest that it is grossly misplaced at this point in the sequence, but its relationships are unclear.

The polytypic genus *Herpsilochmus*, the characteristics of which were reviewed recently by Whitney and J. Alvarez, is well defined, but its relationships with other genera are, once more, uncertain. Molecular studies, mostly employing only one species of *Herpsilochmus*, have variously located it on the same branches as *Dysithamnus* species, *Myrmotherula huxwelli* and *Drymophila* species. Nests of only two of the 15 *Herpsilochmus* antwrens are known, and they are cup-nests suspended in a fork, consistent with nests of the aforementioned species. Various relationships within *Herpsilochmus* have been suggested, these

based on vocalizations, plumage and geography. Clearest among them is a clade consisting of the Caatinga Antwren (*Herpsilochmus sellowi*), the Bahia Antwren (*Herpsilochmus pileatus*), the Black-capped Antwren (*Herpsilochmus atricapillus*), the Creamy-bellied Antwren (*Herpsilochmus motacilloides*) and the Ash-throated Antwren (*Herpsilochmus parkeri*). Superspecies are formed by Dugand's (*Herpsilochmus dugandi*) and the Spot-tailed Antwrens (*Herpsilochmus sticturus*) and by the Ancient (*Herpsilochmus gentryi*) and Todd's Antwrens (*Herpsilochmus stictcephalus*).

Placed in a monotypic genus, the Dot-winged Antwren (*Microrhopias quixensis*) is ripe for a study of species limits as it consists of a number of allopatric populations, most of which have distinct plumages and appear not to intergrade with their neighbours. Morphological characters have put *Microrhopias* close to *Formicivora*, and a suspended cup-nest is built by species in both genera. Gonzaga recently completed an extensive phylogenetic analysis, based on external morphology, syringeal morphology, vocalizations and natural-history characters, of *Formicivora* antwrens and its possible relatives, including the Marsh Antwren (*Stymphalornis acutirostris*). Results revealed that monophyly of *Formicivora* was supported only if the Marsh Antwren was included and the Narrow-billed Antwren (*Formicivora iheringi*) was excluded from the assemblage. The Marsh Antwren, the White-fringed Antwren (*Formicivora grisea*) and the Rusty-backed Antwren (*Formicivora rufa*) were found to form a clade, sister to a clade formed by the Serra Antwren (*Formicivora serrana*), the Restinga Antwren (*Formicivora littoralis*) and the Black-bellied Antwren (*Formicivora melanogaster*). A close relationship between the White-fringed and Rusty-backed Antwrens was also found in a molecular study by Bates and colleagues. The sister-group to *Formicivora* remains uncertain, but results of various molecular studies suggest that the "grey antwren assemblage" is a candidate.

In recent years, the genus *Drymophila* has also received intense study. In a phylogenetic analysis based on mitochondrial DNA, J. M. Goerck found close relationships between three pairs of species: the Ferruginous (*Drymophila ferruginea*) and Bertoni's Antbirds (*Drymophila rubricollis*), the Rufous-tailed (*Drymophila*

*genei*) and the Ochre-rumped Antbirds (*Drymophila ochropyga*), and the Striated (*Drymophila devillei*) and the Long-tailed Antbirds (*Drymophila caudata*). The analysis also indicated a close relationship between the genera *Drymophila* and *Hypocnemis*, as discussed a few paragraphs below here. Nests of *Drymophila*, while not well known, appear to be a deep cup or bag, suspended from above.

*Terenura* concludes the sequence of taxa popularly known as "antwrens". The six species in the genus are similar in size and plumage. On the basis of morphology and vocalizations, however, they are generally recognized as forming three groups: the superspecies comprising the Streak-capped Antwren (*Terenura maculata*) and Orange-bellied Antwren (*Terenura sicki*) of eastern Brazil; the species group made up by the Rufous-rumped (*Terenura callinota*), Chestnut-shouldered (*Terenura humeralis*) and Yellow-rumped Antwrens (*Terenura sharpei*); and, finally, the Ash-winged Antwren (*Terenura spodioptila*). Because *Terenura* antwrens are small and typically occur from mid-heights up to the canopy, much remains to be learned of their distribution and systematics. Indeed, the nest architecture of the genus remains unclear, and its relationships to other groups uncertain.

The thamnophilid sequence continues with 33 antbirds and fire-eyes. These are placed in ten genera, the relationships among which generally remain unclear. Five of the six polytypic genera consist each of species which, according to morphology and behaviour, are closely related. The exception is the genus *Cercomacra*. J. W. Fitzpatrick and D. E. Willard placed ten of the twelve *Cercomacra* antbirds into two species groups, distinguished by female plumage and vocalizations, which they named the "tyrannina group" and the "nigricans group"; the remaining two, the Grey Antbird (*Cercomacra cinerascens*) and the Rio de Janeiro Antbird (*Cercomacra brasiliensis*), were considered intermediate or of uncertain relationship. Salient differences between the groups are emerging. Antbirds in the "tyrannina group" have been found to build deep pouch-nests (see Breeding), whereas species in the "nigricans group" construct cup-nests resembling those of *Thamnophilus* antshrikes and other species discussed above. Furthermore, characteristics of vocalizations,

especially in the forms of duetting (see Voice), while constant within each group, differ between the two. These data suggest that the morphological characters that were used to unite these antbirds in *Cercomacra* could be convergent, and that the genus may not be monophyletic.

A nest architecture that is almost unique among the Thamnophilidae supports a close relationship between the three fire-eyes in the genus *Pyriglena* and the antbirds of the monotypic *Rhopornis* and the polytypic *Myrmoborus*, although the nest description for the Slender Antbird (*Rhopornis ardesiacus*) remains to be confirmed. The domed nest, composed mainly of large dried leaves, palm leaves and twigs and placed on the ground, is often described as an "oven" (see Breeding). Species in these genera regularly pound the tail emphatically downwards and then slowly raise it in a relaxed manner to just above the horizontal, before pounding it down again. This behavioural evidence corroborates the conclusion of Ridgway, who used the morphological characters of bill length, dense feathering of the forehead and lores and absence of rectal bristles when placing *Pyriglena* and *Myrmoborus* sequentially in the taxonomic sequence.

On the other hand, behavioural data suggest that it may have been a mistake to place the two *Hypocnemis* species immediately after *Myrmoborus*. *Hypocnemis* antbirds build suspended nests in the form of a pouch or deep cup, their tail motions are from side to side, and they flick their wings constantly. A recent analysis by Bates and colleagues, employing mitochondrial DNA, indicated that *Hypocnemis* antbirds were closely related to *Drymophila* antbirds, a relationship supported by similarity of nest architecture and of nearly all body motions, as well as by plumage pattern, although the suspended nests of *Drymophila* may not be so deep and the tail motions may vary somewhat among its species. As those authors also pointed out, genetic divergences among populations of the Warbling Antbird (*Hypocnemis cantator*) are substantial. The two species in the next genus, *Hypocnemoides*, may or may not be part of the same lineage as *Hypocnemis* and *Drymophila*. Although the suspended pouch is like most *Hypocnemis* nests, and continuous wing-flicking is also characteristic, the actions of *Hypocnemoides* antbirds differ in that the tail is held partially fanned and cocked at 10

In the traditional taxonomic sequence, the monotypic genus containing the **Spot-backed Antshrike** is placed directly after that of the Fasciated Antshrike (*Cymbilaimus lineatus*). Although there is no direct evidence that any true relationship between these species exists, their overall plumage pattern and bill morphology is similar. However, as the Spot-backed Antshrike appears to be an ecological replacement of the Fasciated Antshrike in the Atlantic Forest, their similarity might be due to convergent evolution. Both species are usually found foraging in tangles of vines in the mid-storey, where they presumably target the same types of invertebrate prey.

[*Hypoedaleus guttatus*,  
Fazenda Capricornio,

Brazil.  
Photo: Arthur Grosset]

The **Tufted Antshrike** belongs to another genus restricted to the Atlantic Forest region. The male of this species is entirely blackish, while the female is dark brown with paler bars. Both sexes possess elongated crown feathers, which are frequently raised into the crest that gives the species its English name. Although currently placed in the genus *Mackenziaena* with the Large-tailed Antshrike (*M. leachii*), the Tufted Antshrike possesses some vocal and plumage characters that suggest a closer relationship to the genus *Frederickena*, which is Amazonian/Guianan in distribution.

degrees above horizontal and is regularly flicked upwards to 30-45 degrees.

Three monotypic genera follow. The Black-and-white Antbird (*Myrmochanes hemileucus*) was thought by Hellmayr to be "nearly related" to *Hypocnemoides*, but evidence confirming this relationship does not yet exist. It is rather a mystery why the Bare-crowned Antbird (*Gymnocichla nudiceps*) was placed here; its large size, bright blue unfeathered ocular region (see Morphological Aspects) and tail-pounding behaviour, along with its domed nest supported by debris atop a broken-off palm, all point to a relationship with antbirds placed later in the sequence, especially *Myrmeciza* species. The Silvered Antbird (*Sclateria naevia*), having a long, thin bill, water-edge foraging habits and side-to-side tail motion, and with its nest unknown, is difficult to place; Hellmayr put it in the same genus as the Spot-winged Antbird (*Pernostola leucostigma*), but no information is available to support such a relationship, and the two species differ in their tail motions.

The final genus in this sixth section, *Pernostola*, seems rather clearly polyphyletic, as exemplified by tail actions. The Black-headed Antbird (*Pernostola rufifrons*) and the White-lined Antbird (*Pernostola lophotes*) pound the tail down and then slowly raise it, whereas the Spot-winged, Slate-coloured (*Pernostola schistacea*) and Caura Antbirds (*Pernostola caurensis*) flick the tail up and then lower it slowly. W. E. C. Todd proposed the shifting of those last three species into a newly erected genus, *Schistocichla*, not an unreasonable proposal and one which some recent authors have adopted, but it seems better to retain them within *Pernostola* pending peer-reviewed analysis of molecular and other characters. No stereotypical tail movements have yet been documented for the newly described Allpahuayo Antbird (*Pernostola arenarum*). The White-lined Antbird may be misplaced in this genus, but its foraging behaviour and tail movements accord with those of the Black-headed Antbird.

The genus *Myrmeciza*, here discussed as a separate section, has been thought by some to be polyphyletic, and Todd proposed placing its 20 species, together with the White-lined Antbird, into five genera. Any phylogenetic reconstruction and consequent taxonomic modifications should, however, consider the relationships of *Myrmeciza* species with antbirds of other genera that share phylogenetically relevant characters, especially *Myrmorchilus*, *Pyriglena*, *Rhopornis*, *Myrmoborus*, *Gymnocichla*, *Sclateria* and *Pernostola*. The diversity of behavioural characteristics within *Myrmeciza* suggests that some of its members are probably related more closely to species of these other groups than to one another. For example, nests are known for 13 *Myrmeciza* species, and all are supported atop substrates (see Breeding), but they vary in shape and location. Nests of the Scallop Antbird (*Myrmeciza ruficauda*), White-bibbed Antbird (*Myrmeciza loricata*), Squamate Antbird (*Myrmeciza squamosa*) and Goeldi's Antbird (*Myrmeciza goeldii*) are open cups placed on the ground. Three ground nests have also been documented for the Ferruginous-backed Antbird (*Myrmeciza ferruginea*), but one of them had a small overhanging cap of twigs and leaves, and this was an even better-developed feature of two ground nests of the Sooty Antbird (*Myrmeciza fortis*), each of which was a spherical chamber with a short entrance tunnel, resembling *Pyriglena* and *Myrmoborus* nests. Other recorded nest-sites were in debris or herbaceous vegetation just off the ground in the case of the Chestnut-backed (*Myrmeciza exsul*), Immaculate (*Myrmeciza immaculata*) and Black-throated Antbirds (*Myrmeciza atrothorax*); along tree trunks on palm rachides or spines or on epiphytic ferns for the Plumbeous Antbird (*Myrmeciza hyperythra*) and White-shouldered Antbird (*Myrmeciza melanocephala*); and in shrubby vegetation near the ground for the White-bellied Antbird (*Myrmeciza longipes*) and Dull-mantled Antbird (*Myrmeciza laemosticta*). The majority of *Myrmeciza* antbirds characteristically pound the tail downwards and then raise it slowly, but a variety of other tail movements has been noted

The genus *Sakesphorus* contains a group of six more or less crested antshrikes allied to the genus *Thamnophilus*. They are mostly inhabitants of drier woodland, gallery forest, flooded forest or scrub. The **Silvery-cheeked Antshrike**, for example, is an inhabitant of caatinga, a thorn-scrub formation in interior Brazil. Throughout the genus, males tend to be boldly marked with black, white or rufous, while the pattern of females is more subdued.

[*Sakesphorus cristatus*, Aracuaí, Mato Grosso, Brazil.

for the Yapacana Antbird (*Myrmeciza disjuncta*), the Grey-bellied Antbird (*Myrmeciza pelzelni*) and the Southern Chestnut-tailed Antbird (*Myrmeciza hemimelaena*), as well as for the Ferruginous-backed, Scalloped, White-bibbed, Squamate and Black-throated Antbirds.

Elements of vocalizations also point to relationships. For example, loudsongs consisting of series of doublets are given by the Ferruginous-backed, Scalloped, White-bibbed and Squamate Antbirds, a fact which, along with plumage similarities, suggests that these four form a closely related group. The loudsongs of the White-shouldered and Goeldi's Antbirds are similar, and the two species are considered to constitute a superspecies, although apparent differences between them in nest architecture require further study. These last two species are of large stature, and similar proportions are found in the Plumbeous, Sooty and Immaculate Antbirds. All five species have been considered related because of their large size and similarly plumaged black males, most with bare blue orbital patches, these being minimal and grey on Goeldi's Antbird, but monophyly of the group has not been demonstrated satisfactorily. The Dull-mantled Antbird and the Esmeraldas Antbird (*Myrmeciza nigricauda*) represent a superspecies, and together with the Stub-tailed Antbird (*Myrmeciza herlepsi*) appear to form a species group. Interestingly, the male of the Esmeraldas Antbird was until recently thought to be of a different species from the female and was even placed in a separate genus, as "*Sipia rosenbergi*", with the Stub-tailed Antbird its sole congener. If future studies show that *Myrmeciza* is polyphyletic, the resurrection of *Sipia* may be warranted.

Most of the remaining 20 species in the sequence, making up the eighth and final section of the Thamnophilidae, are obligate or near-obligate ant-followers. Exceptions are the Wing-banded Antbird (*Myrmornis torquata*) and three of the four species in the genus *Hylophylax*. The Spotted Antbird (*Hylophylax naevioides*), the Spot-backed Antbird (*Hylophylax naevius*) and the Dot-backed Antbird (*Hylophylax punctulatus*), as their names reflect, share similar plumage features; in addition, they all flick the tail up sharply, although shallowly, and drop it more slowly. These three and the Wing-banded Antbird do not appear to be closely related to the obligate ant-followers. Of the four, three have been found to construct suspended

cup-nests like those of the similarly plumaged Banded Antbird and of other species that are placed early in the taxonomic sequence, and unlike nests of remaining species in this final segment of the sequence. The nest of the Dot-backed Antbird is unknown.

The fourth *Hylophylax* species, the Scale-backed Antbird (*Hylophylax poecilinotus*), shares a number of behavioural attributes with members of the obligate ant-following assemblage in the genera *Pithys*, *Gymnopathys*, *Rhegmatorhina*, *Skutchia*, *Phlegopsis* and *Phaenostictus*. The nest of the Scale-backed Antbird and all known nests of the ant-followers are supported from below, rather than being suspended, and are generally placed in hollow stumps, making this the only group of thamnophilids regularly to use such nest-sites. Occasionally, however, some of these antbirds locate the nest elsewhere, including along a palm trunk in leaf sheaves, on the ground or sunk in bundles of sedge, or in the cavity of a live tree. With the exception of the Ocellated Antbird (*Phaenostictus mcleannani*), all of these species lower the tail slowly and then jerk it up rapidly to slightly above the horizontal. Otherwise, the Ocellated Antbird and the Black-spotted Bare-eye (*Phlegopsis nigromaculata*) appear to exhibit long-term relationships between parents and offspring which are perhaps unique within the family (see Breeding).

Aside from the Scale-backed and Ocellated Antbirds, members of the assemblage appear to fall into well-defined groups. Using molecular data, Hackett demonstrated the likelihood of monophyly in *Gymnopathys* antbirds, which she found to consist of two species pairs: the Bicoloured Antbird (*Gymnopathys leucaspis*) and the Rufous-throated Antbird (*Gymnopathys rufigula*) were each other's closest relatives, as were the White-throated Antbird (*Gymnopathys salvini*) and the Lunulated Antbird (*Gymnopathys lunulatus*). Similarities in vocalizations and behaviour support the continued consideration of the five *Rhegmatorhina* antbirds as a clade, while the three species in *Skutchia* and *Phlegopsis* are also probably closely related. More work is needed to define the relationship between the White-plumed Antbird (*Pithys albifrons*) and the very recently rediscovered White-masked Antbird (*Pithys castaneus*), although the latter has been confirmed to be an obligate ant-follower and the loudsongs of the two are similar in qualities.

Looking at the family as a whole, substantial behavioural and vocal differences exist among populations within many species. This is particularly so with a number of thamnophilids inhabiting Amazonia, and these, as Bates has shown, also exhibit a high level of genetic differentiation, which can reasonably be attributed to a combination of the antbirds' sedentary nature and a long history in much of their present locations. Typically, such inter-population differences are reflected less in morphology than in behaviour and vocalizations (see Voice). Isler and colleagues developed a yardstick, based on vocal differences between syntopic congeners with similar morphology, for the objective use of vocalizations as a means of defining species limits. Through this and other methodologies, species-level distinctions are now being found among allopatric populations, and cryptic sympatric

species are coming to light. Since 1990, altogether 19 new thamnophilid species have been recognized: nine of these were previously undescribed, and ten were raised from subspecies or synonymized taxa. Much more work of this nature is needed. Not only is a careful re-examination of species limits in antbirds required in order to provide the basic building blocks for studies of phylogeny and biogeography, but soundly based species definitions are essential to the determining of regions of endemism and land-conservation strategies that will ensure that the wonders of antbird natural history are preserved.

### Morphological Aspects

Antbirds are a morphologically diverse family, ranging in size from the tiny Pygmy Antwren (*Myrmotherula brachyura*), 7.5-8 cm in length and weighing a mere 6-8 g, to the Giant Antshrike, which, with the nominate race at 30-34 cm and 148-155 g, resembles a large cuckoo (Cuculidae) more than it does an antbird.

Structural characters that define the family are either internal, including construction of the syrinx and shape of the sternum, or external but not easily recognized by the non-specialist, such as scutellation of the tarsi, connection of the toes, and details of structure of the upper portion of the bill, or maxilla. With 209 species and such a spectrum of different sizes, other, more obvious aspects of thamnophilid morphology are difficult to summarize. This is reflected in the English names given to various genera and groupings of antbirds by early authors. Names such as "antwren", "antshrike" and "antvireo" reflect superficial similarities in size, shape or bill morphology of the member taxa to those of more familiar groups of Northern Hemisphere birds. Thus, antwrens are small and lively like wrens (Troglodytidae); antvireos are somewhat stockier and bigger-billed, and are generally more phlegmatic, like vireos (Vireonidae); and antshrikes, with their strong, distinctly hooked bills, are reminiscent of true shrikes (Laniidae).

In general, most antbirds have relatively short, elliptical wings, adapted for manoeuvrability in the densely vegetated habitats which they occupy (see Habitat). This is especially evident in two terrestrial species, the Banded Antbird and the Wing-banded Antbird, each of which has exceptionally broad, rounded wings

The genus *Thamnophilus*, the second most species-rich in the antbird family, can be subdivided into a few discrete species groups and species pairs.

Best known amongst these is the "*Thamnophilus doliatus* complex", named after and centred around the common and widespread Barred Antshrike. All members of this complex, such as the

**Chestnut-backed Antshrike**, tend to inhabit tangled undergrowth or secondary habitats, and have heavily barred plumage in at least one sex; they also share similar loudsongs. With its dull, unbarred plumage and more arboreal habits,

the **Mouse-coloured Antshrike** does not belong in the "*T. doliatus* group". Instead, it forms a species pair with the closely related Plain-winged Antshrike (*T. schistaceus*).

These two species are comparatively plain, prefer to forage with mixed-species flocks in the mid-storey of tall humid forest, and have much slower loudsongs than members of the "*T. doliatus* complex".

Below: *Thamnophilus murinus canipennis*, Taisha, Morona-Santiago, Ecuador. Photo: Doug Wechsler/VIREO]

Immediately after *Thamnophilus* in the antbird sequence comes a miscellany of species with obscure ancestries. The first of these, the **Spot-winged Antshrike**, is almost certainly misplaced as it is genetically distant from *Thamnophilus* according to molecular analysis, and possibly more closely related to *Myrmotherula* antwrens of the "stipple-throated group". With foraging behaviour and vocalizations that are unique in the family, this species' relationships remain a mystery.

[*Pygiptila stellaris stellaris*, Cristalino Jungle Lodge, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

for its size. With regard to flight, evolution has emphasized control and high lift efficiency over speed in the *Thamnophilidae*. Broad, rounded wings are "slotted" at the tips, further increasing lift for fast take-off, and are found in a number of birds that sally-glean insects from vegetation. The direct flight of most antbird species is typically somewhat slow and fluttering. It is somewhat faster and more darting in the aerial-hawking genus *Thamnomanes*, which has the same basic wing design as most antbirds but is relatively longer-winged, and in some of the obligate ant-following genera such as *Pithys* and *Gymnophithys* (see Food and Feeding).

Most antbirds possess proportionately large, strong feet and legs, and many have modifications of the toes and soles of the feet that facilitate gripping. These structural adaptations are particularly pronounced in species that cling laterally to the vertical stems and saplings so common in the understorey of tropical forests, and are perhaps best developed in ant-following species in the genera *Pithys*, *Gymnophithys*, *Rhegmatorhina*, *Phlegopsis*, *Phaenostictus* and *Skutchia*. These ant-followers are able to outcompete other birds at ant swarms, largely through their ability to monopolize choice positions close to the most active parts of the swarm. Strong legs and feet allow these birds to cling for long periods to vertical stems, to jump from perch to perch, and to make rapid and acrobatic adjustments to the escape manoeuvres of prey. Less adapted species not only are less manoeuvrable, but also are dependent on more horizontal perches, which are generally less common near the ground and therefore vertically more distant from the swarm front. Leg muscles are said to account for more than 13% of the body weight of one obligate ant-follower, the Bicoloured Antbird. This species and its relatives have the outer two toes of each foot fused at the base, which, along with the partial fusion between the base of toe II and the hind toe, serves to form a broad, flexible sole. This sole is covered by minute projections, which are smooth when the toes are extended, but rough and gripping when the toes are flexed. Antbirds which spend much time in clinging to perches and then flying from perch to perch, as do obligate followers of army ants, tend to have relatively longer claws than those species which spend more time hopping along branches or other substrates. Long legs are useful in allowing constantly moving, perch-gleaning

species, the majority of *thamnophilids*, to reach more foraging substrates from a single perch. In contrast, antshrikes of the genus *Thamnomanes* perch upright for relatively long periods, and then sally to hawk insects from the air or from vegetation. Their relatively shorter legs provide a lower centre of gravity that enhances balance and stability when scanning, at the expense of greater manoeuvrability.

Antbirds in general have a proportionately large bill. That of many of the antshrikes, particularly *Cymbilaimus*, *Frederickena*, *Batara*, *Taraba* and most *Thamnophilus* species, is strongly hooked. One of the longest antshrikes, the Large-tailed Antshrike (*Mackenziaena leachii*), is, however, relatively small-billed, and the bill of yet another large species, the White-bearded Antshrike, is not noticeably hooked. In all antbirds, the maxilla has a subterminal tomial notch, or "tooth", an adaptation that aids in the holding and crushing of chitinous arthropod prey. In larger species, the bill is strong enough to seize and macerate small vertebrates. Unique within the family is the chisel-like, upturned bill of the three species of bushbird, which are divided into two genera, *Neotantes* and *Clytoctantes*, partly on the basis of differences in the bill morphology. The upturned, chisel shape is more exaggerated in the two species of *Clytoctantes*, which have the subterminal tomial notch displaced significantly above the horizontal.

The shape and size of the tail vary widely within the family, and differences have often been used to define genera. Many *Myrmotherula* antwrens have a notably short tail, that of the Pygmy Antwren and Moustached Antwren (*Myrmotherula ignota*) appearing nearly non-existent. Others with a particularly short tail include the Spot-winged Antshrike, the Banded, Wing-banded and Black-and-white Antbirds, and some members of the genus *Hylophylax*. In contrast, the tail of *Drymophila*, *Cercomacra*, *Rhopornis* and *Pyriglena* species is proportionately long and graduated. The Giant Antshrike and the Large-tailed Antshrike have an outsized tail that is proportionately both long and broad.

Antbirds have notably soft plumage, particularly on the back, rump and flanks. The flank feathers of a few species, such as the White-flanked Antwren and males of most *Formicivora* antwrens, are long and silky, and are white or pale grey, contrasting with mostly black body feathers. White-flanked Antwrens of both sexes

display the flanks by constantly flicking the wings, revealing the flanks as a white flash with each flick. Many more antbirds have a contrasting, typically bright white, "interscapular patch" in the centre of the back, this being comprised of all-white feathers or white bases of dark feathers; in a small minority of species, the patch is buff, rufous or grey. Such interscapular patches are normally concealed by dark overlying back feathers and/or dark feather tips. In agonistic display, the overlying feathers are parted to reveal the boldly contrasting patch, which is usually fluffed upwards and flared laterally, such that it may cover the entire back in a number of species. Set against the dim backdrop of the forest interior, the visual effect of a suddenly flared, bright white interscapular patch is striking. In some species, only one sex, usually the male, has such a patch, whereas it is present on both sexes of other species. In a very few cases, the interscapular patch varies in colour between the sexes. Examples include the Dusky-tailed Antbird (*Drymophila malura*) and the Fringe-backed Fire-eye (*Pyriglena atra*), the males of which have a white patch and the females a grey one, and the Rufous-throated Antbird, in which males have a white patch and females a cinnamon-rufous patch. The interscapular patch on some species, such as the male Fringe-backed Fire-eye, is so large that parts of it are visible even when the bird is not displaying or aroused.

Instead of an interscapular patch, other antbirds, such as the Plain Antvireo and the White-shouldered Antbird, have an area of white feathers hidden beneath the scapulars that form a different-shaped patch. This is exposed in agonistic encounters in the same way as other antbirds reveal their interscapular patches. Still other thamnophilids, such as the Immaculate Antbird, have white innermost lesser wing-coverts which are normally concealed by the scapulars and breast feathers; in such cases, a visible line at the bend of the wing is also white. Some species combine different types of patches. The Dot-winged Antwren and some *Cercomacra* species, such as the Jet Antbird (*Cercomacra nigricans*), have both a white interscapular patch and hidden white patches under the scapulars. Members of the genus *Terenura* have

rufous patches on the rump and lower back, although this region is bright yellow on one of them, the aptly named Yellow-rumped Antwren. In agonistic display, males elevate and flare these feathers to such an exaggerated degree that the head is nearly concealed, and the bird resembles a rufous puffball.

Many thamnophilids have elongated crown feathers that can be erected into a bushy or spiky crest. This character is most common among the antshrikes and in some of the obligate and regular ant-following species. Both sexes of the Undulated Antshrike, the Tufted Antshrike (*Mackenziaena severa*), the Glossy Antshrike (*Sakesphorus luctuosus*) and the Black-crested Antshrike (*Sakesphorus canadensis*) have a particularly long, spiky crest that is extremely expressive. Other members of the genera *Frederickena* and *Sakesphorus*, along with *Cymbilaimus* and the Giant, Great and White-bearded Antshrikes, have a somewhat shorter, bushier crest, as do several members of the genus *Thamnophilus*, the latter primarily of the "barred group". The White-lined Antbird has a particularly spiky crest, whereas that of the Black-headed and Sooty Antbirds is shorter and is usually apparent only when the birds are alarmed or during agonistic encounters. All members of the obligate ant-following genus *Rhegmatorhina* have long crown feathers that are typically depressed, forming a noticeable, but lax, crest. During the frequent skirmishes that occur when birds are competing over army-ant swarms, and during territorial or other agonistic encounters, *Rhegmatorhina* antbirds routinely erect their pointed crown feathers into a spiky crest. The sole exception is the Hairy-crested Antbird (*Rhegmatorhina melanosticta*), the crown feathers of which are shorter, filamentous and peculiarly hair-like, and, when erected, form a bushy crest rather than a pointed one. The most conspicuously and perpetually crested of all the thamnophilids is the bizarre little White-plumed Antbird, the tall, white crest of which is nearly always at attention, and is sometimes parted in a bifurcate manner suggestive of some tyrant-flycatchers (Tyrannidae) of the genus *Elaenia*. The White-plumed Antbird's crest is made all the more conspicuous by white plumes on the

The bushbirds inhabit humid forest understorey, where they are usually reclusive and very difficult to see; indeed, those in the genus *Clytactantes* are almost unknown, one having gone unreported since 1965 in Venezuela, the other since 1986 in western Brazil. All three species possess distinctively upcurved lower mandibles. This chisel-shaped design is clearly an adaptation for foraging. The **Black Bushbird** (a female pictured here) spends much of its time hammering at branches, woody vines, palm rachides or rotten logs. When it has opened up an aperture, it pries loose strips of bark or stem fibres, and levers them off using its bill, thereby gaining access to subsurface invertebrate prey.

Alonso]

According to genetic studies, the *Dysithamnus antvireos* belong on the same branch of the family tree as the *Thamnophilus*. They differ in being smaller, with finer bills and different vocalizations. They tend to forage from the undergrowth to the subcanopy of tall forests, generally accompanying mixed-species flocks of insectivores. The **Spot-crowned Antvireo** occurs in the humid forests of southern Central America, and the Chocó region of west Colombia and Ecuador.

[*Dysithamnus puncticeps*, Tinalandia, Ecuador. Photo: J. S. Dunning/VIREO]

chin that form a "beard" on each side. When viewed head-on, the laterally splayed beard and the tall crest create a striking white arrowhead shape against an otherwise black face.

Aside from the above examples, the presence of ornamental plumes of any kind is rare among the *Thamnophilidae*. The poorly known Pale-faced Antbird (*Skutchia borbae*) has a small patch of stiffened black feathers above each eye, and a much larger conspicuous patch of whitish feathers occupying the loreal region. This loreal patch is reminiscent of similar patches of elongate feathering found on some species of puffbird (*Bucconidae*) of the genus *Malacoptila*. The monotypic genus *Xenornis*, the single species of which, the Speckled Antshrike, has been known by various English names, including "Spiny-faced Antshrike", is in part characterized by well-developed but short black bristles in the loreal area, below the eye, around the gape and on the chin. This bird forages primarily by darting sallies to live foliage, which frequently involves forceful contact between the head and the vegetation; the concentration of stiff bristles around the eye may serve to protect it during these violent strikes. Two species of *Thamnomanes*, the Cinereous and the Bluish-slate Antshrikes, both of which are also sally foragers, have bristle-like feathers on the lores, along the edge of the maxilla and in the gular region. These are well developed, and resemble the rictal bristles of tyrant-flycatchers, but with the rachis less stiffened and the distal barbs more fully developed. The function of rictal bristles has never been clearly determined, but one of the more plausible theories is that these stiffened feathers act to deflect flying insects away from the eyes of aerial feeders. Interestingly, the two remaining species of *Thamnomanes* lack bristles, although they have semi-bristles, a feather type intermediate between true bristles and contour feathers, distributed in the areas where bristles are present on the Cinereous and Bluish-slate Antshrikes.

A number of antbirds have prominent areas of contrastingly coloured bare skin on the face, particularly around the eyes. On some species, this skin may appear, under normal conditions, as little more than a well-developed eyering, but it is highly flexible and can be enlarged by retraction of adjacent feathers, so that birds in alarmed or agonistic modes may present a striking, big-eyed appearance. This is particularly prominent among the regu-

lar and obligate followers of army ants. All members of the genus *Rhegmatorhina* have prominent periorbital patches, giving them a distinctive goggle-eyed look. The patch is pale bluish-white on the Chestnut-crested Antbird (*Rhegmatorhina cristata*) and the Hairy-crested Antbird, greenish-yellow on the White-breasted Antbird (*Rhegmatorhina hoffmannsi*), and bluish-green or glaucous green on the Bare-eyed Antbird (*Rhegmatorhina gymnops*) and the Harlequin Antbird (*Rhegmatorhina berlepschi*). The periorbital patch is particularly large on the Bare-eyed Antbird, which, as Willis pointed out, is especially prone to swinging around perches and staring at the observer in a way that shows off both eye-patches simultaneously. Willis speculated that the pale "goggles" of *Rhegmatorhina* antbirds, surrounding, as they do, a dark eye, may function as the "iris" in an eyespot design, scaring away potential predators or frightening competitors of the same or other species (see General Habits). Similar but somewhat smaller bluish bare patches surround the eyes of the Rufous-throated and Bicoloured Antbirds, although not those of their congeners the White-throated and Lunulated Antbirds, and are present also on the Sooty, Immaculate, Plumbeous, Chestnut-backed and Ferruginous-backed Antbirds, being bright blue on the last of those species. Smaller still are the bare bluish areas of skin around the eyes of the White-shouldered, White-bellied and Wing-banded Antbirds, whereas the bright blue skin surrounding the eye of the Ocellated Antbird extends to much of the face, and is more striking and extensive than on even the *Rhegmatorhina* species. The two bare-eyes, in the genus *Phlegopsis*, resemble *Rhegmatorhina* in having extensive bare goggles, but the skin is bright red. The red goggle is equally well developed in both sexes of the Black-spotted Bare-eye, but is reduced to a narrow, teardrop-shaped eyering on the female Reddish-winged Bare-eye (*Phlegopsis erythroptera*). The Pale-faced Antbird, formerly placed in the same genus as the two bare-eyes, has only a small triangle of greyish-white skin behind the eye. The ultimate expression of these tendencies towards brightly coloured, bare facial skin is to be found in the monotypic genus *Gymnocichla*, the Bare-crowned Antbird, which is distinguished by the male having the entire forecrown, the periorbital region and much of the face naked and bright blue. The female, on the other hand,

has only the orbital region bare and blue, suggesting that this species, rather than constituting a distinct genus, may merely represent one end of the range of character variation seen in the genus *Myrmeciza*.

While most antbirds have dark eyes, there are numerous exceptions. A number of species have reddish-brown eyes that appear brighter red in the sunlight, but dark brown in the shade. Vivid red eyes are found in the Fasciated Antshrike (*Cymbilaimus lineatus*), the Great and Black-throated Antshrikes, all of the fire-eyes, the Slender Antbird, the Ash-breasted (*Myrmoborus lugubris*), Black-faced (*Myrmoborus myotherinus*) and Black-tailed Antbirds (*Myrmoborus melanurus*), the Esmeraldas, Dull-mantled and Goeldi's Antbirds, and in two races of the Black-headed Antbird. Those of the Rufous-capped and Rufous-winged Antshrikes and the Stub-tailed Antbird are somewhat duller reddish, while the eye colour of Undulated Antshrikes varies from brown to pale orange and pale yellow. Four *Thamnophilus* species, the Barred, Lined (*Thamnophilus tenuipunctatus*), Bar-crested (*Thamnophilus multistriatus*) and Chestnut-backed Antshrikes (*Thamnophilus palliatus*), have glaring yellow or straw-yellow eyes, although eye colour of the Barred Antshrike varies racially, with the north-east Brazilian subspecies *capistratus* having chestnut-brown eyes; the colour also varies within some Barred Antshrike populations. The pale grey eyes of the Pearly Antshrike give it a unique facial expression. Grey eyes are found also in the Uniform and Speckled Antshrikes, the Black-chinned (*Hypocnemoides melanopogon*) and Band-tailed Antbirds (*Hypocnemoides maculicauda*), the Slate-coloured Antbird, two races of the Black-headed Antbird, and the Spot-backed Antbird. Iris colour of several antwrens of the "stipple-throated group", including the White-eyed Antwren (*Myrmotherula leucophthalma*), Brown-bellied Antwren, Checker-throated Antwren (*Myrmotherula fulviventris*), Stipple-throated Antwren (*Myrmotherula haematonota*) and Foothill Antwren (*Myrmotherula spodionota*), varies from whitish to pale grey, to pale orange, and to hazel-brown. Some of this variation has been shown to be age-related, but the extent of sexual and individual variation is not well understood. Observers attempting to determine the eye colour of forest birds need to exercise caution. In the gloom of the forest interior, birds' pupils often dilate to the extent that a pale iris may be exceedingly difficult to detect.

Apart from the bare facial skin and eye colour, antbirds show little variation in bare-part coloration when compared with that found in other avian families. Bill and tarsus colours range from grey to blue-grey to blackish in most species. Paleness of bill colour is a distinguishing character in a few closely related pairs. Several species have pinkish legs and feet, including the Silvered Antbird, some races of the Spot-winged Antbird, and the White-bellied, Squamate, White-bibbed, Scalloped, Spot-backed, Rufous-throated and Ocellated Antbirds. The legs and feet of White-plumed Antbirds are bright orange-yellow.

Antbirds are not brightly coloured. Nonetheless, many are attractively patterned in black and white or various tones of rufous, chestnut, buff or brown. Several, such as the Giant and Large-tailed Antshrikes, the Yellow-browed Antbird (*Hypocnemis hypoxantha*), the Ferruginous-backed, White-plumed and Ocellated Antbirds and the Reddish-winged Bare-eye, are truly striking and, arguably, are among the most attractive of Neotropical birds. Sexual dimorphism is the rule rather than the exception in the Thamnophilidae, and plumage differences between males and females of the same species are often pronounced. In general, males tend towards combinations of grey, black and white, whereas females tend towards brown, rufous and buff. Many species have patterns of bars or spots on the upperwing-coverts, these often being white tips or fringes of black or grey feathers on males, whereas females tend to have golden, buff or rufous tips or fringes of brown feathers. Males of many species have a black throat or bib, which is usually lacking on the females. Males of many thamnophilids are uniformly grey or black on the upperbody and underbody, while females of the same species are more often bicoloured, being darker or duller brown above and whitish, buffy or rufescent below. In some species the males, too, are brown-backed, but they have grey underparts.

An important tendency within the family is for females to exhibit a greater degree of geographical plumage variation than males. There are numerous antbird species in which female characters differ more than do those of males, these being, as Hellmayr pointed out, examples of "heterogynism". A few instances will suffice here. Male Dot-winged Antwrens are fairly similar throughout the species' broad geographical range, differing primarily only in the amount of white in the rectrices. The females, however, differ diagnosably, and in some cases strikingly, among the ten subspecies. Females of most races are slate-grey to sooty blackish above, and variably cinnamon, rufous or chestnut below, some races having grey flanks; as with males, they differ also in the amount of white tipping on the rectrices. Females of the nominate race differ further in having a black throat with rufous-chestnut breast and belly, whereas females of the race *nigriventris* have a black throat, a deep chestnut breast and a black belly and crissum, and those of the race *emiliae* have the throat and breast a deep chestnut and the belly black. For the most part, White-fringed Antwren males throughout their broad range differ only in darkness, the race *orenocensis* being the exception in having reddish yellow-brown upperparts. In contrast, females of the various subspecies vary strikingly in the colour and pattern of the underparts, some races being whitish with a cinnamon or buff tinge, one race orange-rufous, others being whitish with dusky or black streaking on the breast, and one race having white underparts with heavy black streaking throughout. Even more striking variation is evident among White-backed Fire-eye (*Pyriglena leuconota*) females. Those of the nominate race are dark rufescent brown above, with brownish-grey auriculars, and have the throat and breast pale buff and the lower underparts dark yellowish-brown. Females of the races *marcapatensis*, *hellmayri* and *maura* are similar to the nominate race, though yellower above, and, more noticeably, have a white eyebrow and

Amongst the most conspicuous features of the Amazonian avifauna are the mixed-species understory flocks.

These flocks are largely composed of antbirds, and usually led by one or two species of Thamnomanes antshrike, such as the Dusky-throated Antshrike.

These antshrikes are usually rather noisy and excitable, adopting an upright stance on open perches in the lower or middle storey, and sally-gleaning insects from foliage. Genetic analysis indicates that they are not closely related to Thamnophilus species.

[*Thamnomanes ardesiacus ardesiacus*, Zancudo Cocha, Napo, Ecuador. Photo: Doug Wechsler/VIREO]

Containing 35 species, *Myrmotherula* is the most diverse genus in *Thamnophilidae*. It embraces an assortment of diminutive antwrens with thin warbler-like bills. It is probably polyphyletic, as these birds can be grouped into three distinct lineages: the "streaked", the "stipple-throated" and the "grey" assemblages. Members of the first group, including the **Pacific Antwren**, are noted for their striking plumage and distinctive nest structure. Despite its unmarked throat, the **Rufous-tailed Antwren** belongs in the "stipple-throated antwren" clade. Members of this group have a distinctive foraging technique which consists of probing for insects in hanging clusters of dead-leaves, and they also differ from other *Myrmotherula* species in their plainer, browner plumage, their nest architecture, their vocalizations and their territorial displays; in addition, they tend to have pale eyes. In fact, they are probably rather distantly related to their congeners. The **Star-throated Antwren**, an Atlantic Forest endemic, is sometimes included as an outlier of this group on the grounds that it has a stippled throat; however, its nest architecture is different, its loudsong is unusual, and it is not a dead-leaf specialist, as are all other members of the "stipple-throated assemblage". It may, in fact, be most closely related to the **Rufous-bellied** (*M. guttata*) and **Plain-throated Antwrens** (*M. hauxwelli*), an aberrant species pair which may form a separate clade from the "grey" assemblage.

Bottom: *Myrmotherula gularis*, Cantareira, São Paulo, Brazil. Photo: Edson Endrigo]

*Herpsilochmus antwrens* are larger and more robust than other canopy-dwelling antwrens, such as those of the genus *Terenura* and the few canopy-inhabiting species of *Myrmotherula*. In shape and foraging behaviour they are vaguely reminiscent of some warblers, notably *Dendroica* of the New World or *Sylvia* of the Old World. Most of them, including the **Large-billed Antwren**, have dark or well-streaked caps bordered by paler supercilia. This species tends to inhabit gallery forests and the edge of dry forest in interior Brazil and adjacent Bolivia. The genus as a whole is fairly evenly split between humid-forest species and those of drier formations.

subocular spot; females of *pacifica* are dark reddish yellow-brown above and greyish olive-brown below; female *castanoptera* is chestnut-brown on the back, but the head and underparts are dull blackish, whereas *picea* is dark reddish yellow-brown except for a brownish-black head; and females of the race *similis* are rich rufous-brown all over, with a contrasting blackish head. Males of these various subspecies of the White-backed Fire-eye are nearly indistinguishable in plumage.

The importance of heterogynism in antbird morphology can also be seen when comparing closely related species within the same genus. In many species complexes, the males vary from being nearly inseparable by plumage characters to representing only minor variations on a common theme, whereas females of these same species differ more strikingly. Examples include the “*nigricans* group” in the genus *Cercomacra*, in which males of the Rio Branco Antbird (*Cercomacra carbonaria*), Jet Antbird, Bananal Antbird (*Cercomacra ferdinandi*), Manu Antbird (*Cercomacra manu*) and Mato Grosso Antbird (*Cercomacra melanaria*) are all extremely similar to one another morphologically, while their respective females are all readily distinguished. The same is true of species pairs of *Thamnomanes* antshrikes, and applies also to the Plumbeous and White-streaked Antwrens, the White-fringed and Black-bellied Antwrens, the Amazonian Streaked (*Myrmotherula multistriata*) and Guianan Streaked Antwrens (*Myrmotherula surinamensis*), members of the genus *Herpsilochmus*, and the White-shouldered and Goeldi’s Antbirds. In a rare exception to the general rule, females of the Lined and Chestnut-backed Antshrikes are very similar to one another, but males of the former species are barred black and white throughout, whereas males of the latter have a solidly black crown and bright rufous-brown upperparts.

Not all antbirds exhibit strong sexual dimorphism. This holds especially for obligate ant-followers. Sexes of the Pale-faced, Ocellated, White-plumed and White-masked Antbirds and of the Black-spotted Bare-eye are essentially monochromatic, but, interestingly, three other members of the assemblage, the Lunulated and White-throated Antbirds and the Reddish-winged Bare-eye, are strongly sexually dimorphic. The sexes of the Rufous-throated

Antbird are distinguished mainly by having differently coloured interscapular patches; and, although Bicoloured Antbirds west of the Andes are essentially monomorphic, females east of the Andes have a cinnamon interscapular patch, lacking on males. Other examples of species or genera that show only slight dimorphism between the sexes are the Spot-backed Antshrike (*Hypodaleus guttatus*), the Glossy and Streak-backed Antshrikes (*Thamnophilus insignis*), in which the sexes differ mainly in crown colour, the Russet Antshrike, differing sexually only in presence or absence of an interscapular patch, Castelnau’s Antshrike, the “streaked antwren assemblage” of *Myrmotherula*, the genus *Drymophila*, and the Banded, Black-and-white, Grey-headed (*Myrmeciza griseiceps*), Chestnut-backed and Dull-mantled Antbirds.

There are some interesting plumage parallels between thamnophilid species that are not closely related. Both sexes of the Cocha Antshrike, a poorly known bird restricted to the lowlands of eastern Ecuador, bear an uncanny resemblance to the corresponding sexes of the White-shouldered Antbird, a more widespread Amazonian species with which the antshrike is partly sympatric. Males of both are glossy black, the male White-shouldered Antbird having some white, which is often concealed, near the bend of the wing; females of both species have the head, throat and chest black, with bright rufous upperparts and paler, cinnamon-rufous underparts. Thus, the two species appear nearly identical, except for a small amount of bare bluish skin found around the eye on both sexes of the White-shouldered Antbird. A similar parallel is seen between both sexes of the Narrow-billed Antwren, a threatened endemic of dry forest in north-eastern Brazil, and the corresponding sexes of the east Brazilian race *luctuosa* of the White-flanked Antwren. With each of these examples, there are clear structural, vocal and ecological differences separating the taxa, and yet their plumage characters are amazingly similar. Some parallels exist also between some antbirds and some members of the Furnariidae. The Russet Antshrike, with its rufescent wings and tail, duller brown mantle and rich ochraceous-buff eyebrow and underparts, bears a strong resemblance to several species of foliage-gleaner of the

**The Dot-winged Antwren** is placed in a monospecific genus that is probably most closely allied to the Formicivora antwrens. Unlike them it is generally a bird of humid forests. Ten subspecies are currently recognized, some of which may soon be elevated to full species, given apparent vocal differences and lack of intergradation at points of parapatry. As it stands, this species is an example of heterogynism: the males of various races are similar while females differ radically. Females of the race *consobrinus* have the entire underparts rufous, while, across the Andes, females of the various races usually have black throats or black bellies.

[*Microhierax quixensis consobrinus*, Antioquia, Colombia. Photo: J. S. Dunning/Ardea]

genus *Philydor*, some of which occur in the same mixed-species canopy flocks with the antshrike. Even more striking, as Willis pointed out, is the resemblance between the female White-bearded Antshrike and both sexes of the White-collared Foliage-gleaner (*Anabazenops fuscus*); these two bamboo specialists, confined to the Atlantic Forest, often occupy the same bamboo thickets in parts of Brazil.

Juvenile males of many species resemble adult females in plumage characters. Older subadult males of these species will show individually variable and often confusing combinations of adult male and adult female plumage characters. The Spot-winged Antbird serves as just one example. Adult males are grey throughout, with white-dotted wing-coverts, while adult females have a grey crown but are brown-backed, with buff-dotted wing-coverts and rich ochraceous-buff underparts. Subadult males can have the head and underparts entirely grey, like adult males, but with the back, wings and tail brown, like adult females, and with a combination of white-spotted grey coverts and buff-spotted brown coverts on the wing.

The tendency of subadult males to resemble adult females has, in some instances, led to confusion over both plumages and taxonomy. For example, the sexes of the White-lined Antbird were originally described as two different species. In 1914, Hellmayr and J. G. von Seilern described *Pernostola lophotes* from a specimen that was almost certainly a subadult male; this bird was conspicuously crested, rufous above and whitish below, and with blackish primary coverts. Subsequent female specimens were collected that resembled the type, except for having rufous primary coverts. This species went by the English name of "Rufous-crested Antbird". In 1966, Berlioz described a single adult male specimen as *P. macrolopha*, the "White-lined Antbird"; this bird was also conspicuously crested, but was entirely blackish except for white fringes on the upperwing-coverts and white underwing-coverts. The female of *macrolopha* was considered unknown for more than a decade. It remained for T. A. Parker to sort out the confusion surrounding these two taxa. Parker's fieldwork in the Tambopata Reserve of Madre de Dios, in Peru, showed that "*P. macrolopha*" was clearly the male of *P. lophotes*. The blackish primary coverts of the type speci-

men of *lophotes* represented the first emerging adult male characters of a bird that was otherwise female-plumaged, and led to the mistaken conclusion that the sexes of *lophotes* were nearly identical to one another in plumage.

It is thought that temperate-zone birds keep the moulting and breeding periods apart, given the high resource requirements of the two events. As summarized by M. S. Foster, however, overlap between the moult and breeding cycles is widespread among birds living near the equator. Included in the studies on which Foster drew was that of D. W. Snow and B. K. Snow, who kept track of evidence of moult in individuals of the Barred Antshrike that they netted in Trinidad. Those authors found that, in nearly every month of the year, approximately half of the individuals trapped were in moult; in addition, irregularities in the sequence of wing moult were common among these individuals. Seeking to relate the cycle of moult with breeding in the same area, they searched for, and found, nests of the Barred Antshrike in every month of the year except two. Snow and Snow's tentative conclusion was that the population of the species as a whole had no well-defined annual cycle, although it is possible that individual pairs may have annual periods of moult and nesting.

## Habitat

The Thamnophilidae are entirely Neotropical in distribution, with only relatively few species reaching southern Mexico and northern Argentina. They occur on islands only near continental shores, such as Coiba Island and the Pearl Islands, off Panama, Gorgona Island, off Colombia, Margarita Island, off Venezuela, Tobago, and small islands immediately off the coast of southeastern Brazil.

The vast majority of thamnophilid antbirds inhabit lowland and foothill humid evergreen forest. The family reaches its greatest diversity in the Amazon Basin, where 40-45 species occur syntopically at various sites in Colombia, Brazil, Peru and Bolivia. Examples of such localities are the Tapajós National Park, Alta Floresta and Cachoeira Nazaré, in Brazil, the Tambopata-

The *Formicivora antwrens* are strikingly marked birds of brushland and dry forest habitats, mostly in Brazil. This **Black-bellied Antwren** displays some of the group's common morphological themes, namely the black underparts of males and the gleaming white supercilium separating a dark face from a brown cap. Their sister-group has not been identified, but results of various molecular studies suggest that it might be the "grey antwren assemblage" of *Myrmotherula*.

[*Formicivora melanogaster bahiae*, Ceará, Brazil.

Photo: Luiz Claudio Marigo]

Candamo Reserved Zone and Manu Biosphere Reserve, in Peru, and the Lower Rio Heath, straddling the Peru-Bolivia border. By comparison, antbird species diversity at single sites in the Guianan lowlands of southern Venezuela, Guyana, Surinam and French Guiana typically peaks at 25-35 species. Diversity tapers off rapidly in Central America, with totals of 30 species for all of Panama, 22 for Costa Rica and only seven for Mexico, and similar reductions are evident in Venezuela north of the Rio Orinoco and in the area south of the southern fringes of Amazonia. The Atlantic Forest of eastern Brazil, north-eastern Argentina and southern Paraguay has a highly endemic antbird fauna, but seldom do more than 16 thamnophilid species occur together at a single site within this region. Antbirds are altogether absent from much of Argentina and all of Chile. Species diversity also falls off rapidly with increasing elevation in mountainous regions; fewer than 10% of all species occur above 2000 m, and none occurs regularly above 3000 m. Most members of the family are arboreal, ranging from just above ground to the canopy, but a few are primarily or exclusively terrestrial. Examples of the latter include the Banded Antbird, the Wing-banded Antbird, the Stripe-backed Antbird and several members of the genus *Myrmeciza*.

The lowland humid and wet forests of Central and South America are far from homogeneous, and in fact represent a mosaic of different forest types, all of which are inhabited by antbirds. *Terra firme* is upland forest, situated on slightly elevated shelves and beyond the reach of flooding rivers that overflow their banks during the rainy seasons. This is the tallest and, usually, the most floristically and faunistically diverse of the lowland humid forests. It is in the *terra firme* forests of the Amazon Basin that the family Thamnophilidae reaches its zenith of diversity. Despite the fact that such forests represent the single richest habitat for antbirds, it is the contribution made by a variety of other forest types and by micro-habitats within the forest that elevates the species diversity of antbirds in Amazonia above that found in the more northern Guianan and Chocó lowlands. The availability of numerous habitats and micro-habitats within small geographical areas allows for habitat and resource specialization, which, in turn, promotes greater resource-partitioning and species-packing.

Somewhat less physically imposing and less diverse than the *terra firme* forests are the bands of forest, sometimes many kilometres wide, which border rivers and freshwater lagoons, and which are subject to periodic flooding during the rainy seasons. *Várzea* is forest that is seasonally flooded by muddy, white-water rivers, whereas the term *igapó* is more properly applied to both permanently flooded and seasonally flooded forest bordering black-water rivers. White-water rivers are so called because of the milky appearance caused by an abundance of suspended silt in the water, whereas black-water rivers derive their name from the dark tea-like appearance caused by an abundance of tannins. Black-water rivers drain sandy-soil forests rich in tannin-producing plants. A number of antbird species inhabit seasonally flooded forest, and some are seldom found far from river, stream and lake-edge forest and adjacent second growth. These last include such species as the Glossy and Castelnau's Antshrikes, the Amazonian Streaked and the Guianan Streaked Antwrens, Klages's Antwren (*Myrmotherula klagesi*), the Leaden Antwren, and the Band-tailed, Black-chinned, Ash-breasted and Silvered Antbirds.

The Amazon and its larger tributaries are also liberally sprinkled with islands of varying ages and at different stages of development. River islands are created in one of two ways: either a meandering river cuts a new channel, carving off and isolating land that was previously connected to the main bank, or new islands can form from sandbars, usually during low-water seasons when sandbars are first exposed and then are enlarged by silt deposition. Those formed by the first process are sometimes referred to as "oxbow islands", and the flora and fauna of such an island are initially identical to, or a subset of, those on the main riverbank from which it came. In contrast, river islands formed from sandbars begin with no vegetation at all, but they are quickly colonized by pioneer plant communities. Grasses yield rapidly to a sandbar scrub community composed of willows (*Salix*), the willow-like composite *Tessaria integrifolia* and another composite shrub, *Bacharis*, the whole taking three or four years to mature. The *Tessaria*-dominated scrub community is, in turn, replaced by dense stands of *Gynerium* cane, growing to several metres in height. The cane is eventually overtopped by young

The *Drymophila* antbirds are united by a suite of shared characters: raspy songs, streaky or rufescent plumage, long tails and a predilection for creeping through patches of bamboo. Although the **Long-tailed Antbird** is the only Andean representative of this group, a thorough analysis of regional variations, and the presence or absence of interbreeding at the junction between races, may reveal that this taxon, as currently understood, really comprises two or more species.

[*Drymophila caudata*.  
Photo: J. S. Dunning/  
Ardea]

stands of *Cecropia* forest, which, in turn, are gradually overtopped by figs (*Ficus*) and other species more typical of mainland riverbank forest. These same successional dynamics take place continually on established islands in silt-laden white-water rivers. Islands are constantly eroded on their older, upstream ends, while silt and sand are continually deposited on the younger downstream end, laying the groundwork for beach formation and the same successional processes as those outlined above.

Oxbow islands and the upstream ends of older sandbar islands are usually populated by the same *várzea* and *igapó* birds as are found on the adjacent main riverbanks. A number of avian species have, however, evolved to capitalize on the newly created successional habitats that arise during river-island formation and maturation. These are the true river-island specialists, and, as first pointed out by J. V. Remsen and Parker, many of them are rarely, if ever, recorded away from river islands. In one of the first studies to evaluate the degree of ecological specialization among river-island birds, G. H. Rosenberg found that, in north-eastern Peru, four of 18 species that appeared to be restricted to river islands were thamnophilid antbirds. These were Castelnau's Antshrike, the Leaden Antwren, the Ash-breasted Antbird and the Black-and-white Antbird. Of these, the first three were largely confined to pure stands of *Cecropia* forest. The Black-and-white Antbird is a specialist of the younger stages of succession, being most common in the *Tessaria*-scrub habitats, but also utilizing rank grass, cane, and thickets of *Heliconia* and other broadleaf plants in the understorey of the *Cecropia* groves.

The term "gallery forest" is most accurately applied to narrow riparian belts of forest that follow watercourses in otherwise drier, often non-wooded environments. These, too, may flood seasonally, and they share a number of floristic and faunal similarities with *várzea* or *igapó* of nearby regions. Despite this, some bird species are restricted to gallery forest, one example being the globally threatened Rio Branco Antbird, found in gallery forest bordering the Rio Branco and its tributaries in northern Roraima, in Brazil, and immediately adjacent southern Guyana. Among the antbirds that are locally common in gallery forest are the Barred, Great and Black-crested Antshrikes, the Large-billed Antwren (*Herpsilochmus longirostris*) and the Band-tailed, Black-chinned, Mato Grosso and White-bellied

Antbirds. Some gallery forests are characterized by an abundance of palms, particularly moriche or buriti palms (*Mauritia flexuosa*). Where these grow in essentially pure stands, often in low-lying, swampy ground, they are better termed "palm forest". Antbirds are not well represented in palm forest, but some species, such as the Large-billed Antwren and the White-bellied Antbird, occupy such habitats locally.

Along the Caribbean coast, mangrove swamps provide an array of successional stages from subpioneer to the oldest, not unlike the stages of island formation. In French Guiana, as described by O. Tostain, the Black-crested Antshrike occupies all seven stages, the Blackish-grey Antshrike and the White-fringed Antwren inhabit the middle stages, while the older stages are colonized by species more typical of riparian habitats in the interior, such as the Guianan Streaked Antwren and the Black-chinned, Silvered, Black-headed and Black-throated Antbirds. With the exception of the Blackish-grey Antshrike, the relevant race of which, *kulczynskii*, appears to be confined to French Guiana and immediately adjacent Brazil, these same species, especially the Black-crested Antshrike and White-fringed Antwren, can be found in mangrove stages along the coast of Surinam, Guyana and north Venezuela.

An under-appreciated class of habitats occupied by many antbirds is labelled collectively as Amazonian white-sand forest. The term "Amazonian *caatinga*" has been proposed, to encompass the various white-sand habitats of the region, but it has not gained universal acceptance. These forests are very patchily distributed, covering about 60,000 km<sup>2</sup> in Brazil alone, and a nearly equivalent area outside that country, primarily in southern Venezuela and other parts of the Guianan Shield, south-eastern Colombia and, to a lesser extent, north-east Peru. The distributional centre of the habitat is in the upper Rio Negro region, but it occurs locally throughout Amazonia. These forests are characterized by sandy soils containing virtually no clay, and which are extremely nutrient-poor, or leached, with poor water retention. The exact structure of white-sand forest varies tremendously from site to site, ranging from dense savanna scrub to tall forest growing to 30–40 m, such that the formation as a whole is more of a patchwork or habitat mosaic than a single habitat. In general, white-sand forests are stunted and species-depauperate, but with a high degree of endemism. Characteristic dominant families of

The genus *Cercomacra* includes twelve furtive species with fairly long tails and dull plumage, usually grey or black in males, brown or rufous in females. Ten of these species can be split into two groups. One of these, centred around the **Dusky Antbird**, is characterized by deep pouch-nests, the other by shallow cup-nests. There are also vocal differences, suggesting that the morphological similarity between these two groups might be due to convergence rather than ancestry, in which case *Cercomacra* would have to be subdivided. The two final species in the genus are either intermediate or indeterminate in position.

[*Cercomacra tyrannina crepera*,  
Carara Biological Reserve,  
Costa Rica.

woody plants include Leguminosae, Euphorbiaceae, Sapotaceae, Guttiferae, Rubiaceae and Myristicaceae. These habitats are known locally by many different names; in Amazonian Brazil they are often referred to as *campina* or *caatinga*, the latter not to be confused with the xeric scrublands of the same name in north-eastern Brazil.

Long ignored, white-sand habitats are now coming under increasing scrutiny from ornithologists, largely in response to many significant recent discoveries. Several of these involve thamnophilids. Three species, Cherrie's Antwren (*Myrmotherula cherriei*), the Grey-bellied Antbird and the Yapacana Antbird, were long known from specimens, but were virtually unknown in life prior to 1990. All have proven to be largely or entirely restricted to sandy-soil forest. Of these three, the Yapacana Antbird is perhaps the most specialized and the most intriguing. For decades it was known only from seven specimens collected between 1931 and 1947 in the vicinity of Cerro Yapacana, an isolated tepui, or tabletop mountain, in Amazonas, south Venezuela; no habitat description accompanied the specimens, and later authors, perhaps describing the general environment surrounding Cerro Yapacana, listed the antbird's habitat as high rainforest at about 100 m. Over the next 50 years, a female mist-netted in sandy-soil forest in south-eastern Colombia in 1981 and another collected in "tall seasonal rain forest" in extreme southern Venezuela in 1984 provided the only subsequent records, neither of which shed significant light on the habitat requirements of what had become something of a mystery species. Then, in 1997, the Yapacana Antbird was rediscovered by J. Coons and D. Stejskal in white-sand forest near the Venezuelan settlement of Picua, on the south bank of the Río Ventuari, also in Amazonas. In the following year, detailed investigations by K. J. Zimmer revealed that, although there were different types of white-sand forest in the Picua area, the Yapacana Antbird seemed to live only in a habitat known to local people as "*monte cerrado*". This was a stunted, virtually impenetrable woodland growing on fine, compacted white-sand soils that are seasonally saturated. The canopy varied from 6 m to 10 m, with few trees thicker than 10 cm in diameter, and with abundant vines, sawgrass and bamboo in the understorey. Within this specialized habitat, the Yapacana Antbird proved to be locally abundant. Subsequent to the unravelling of this mystery, populations of the species were discovered in Brazil for the first

time; these were also in dense white-sand forest resembling the *monte cerrado* of Venezuela.

In the early 1990s, Alvarez and Whitney began to document a unique avifauna from white-sand forests near Iquitos, in Loreto, north-western Peru. A series of discoveries followed, which has, to date, produced published descriptions of three new species and a new subspecies, with three of the four newly described taxa being antbirds. The Ancient Antwren, the Allpahuayo Antbird

The **White-shouldered Fire-eye** is an endemic of the Atlantic Forest of south-east Brazil, east Paraguay and north Argentina. It shares the genus *Pyriglena* with two other species, forming a neat unit. Males of all three species are largely black, with varying amounts of white on the wings or mantle. Females are more variable, even between races of the same species (another example of heterogyny). Both sexes have the fiery eyes, a feature that is surprisingly conspicuous in the dark forest understorey.

[*Pyriglena leucoptera*,

São Paulo, Brazil.  
Photo: Edson Endrigo]

The **Black-faced Antbird** is one of four species in *Myrmoborus*, a genus whose relationship with the fire-eyes (*Pyriglena*) is supported by nest structure and stereotypic tail movements – they all pump their tails down and let them rise slowly. As in the fire-eyes, dimorphism is pronounced, with males (left) mostly grey and black, and females paler with dark masks (right).

[Left: *Myrmoborus myotherinus ochrolaema*, Cristalino Jungle Lodge, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo.

Right: *Myrmoborus myotherinus sorious*, Fazenda Rancho Grande, Rondonia, Brazil. Photo: Kevin Zimmer]

and the Northern Chestnut-tailed Antbird (*Myrmeciza castanea*) have all been found to inhabit two distinct types of forest growing on nutrient-poor soils. One is a very dense and stunted *terra firme* forest, of a type called *varillal* by local inhabitants, which grows on nearly pure white-sand soils, and which is dominated by saplings of such white-sand specialists as the palm *Euterpe catinga*, and by *Caraipa* species (*Clusiaceae*). The other, known locally as *irapaya*, is a taller forest, to 40 m. growing on old, weathered clay soils as well as on sandy soils, and with a dense understorey of irapay palms (*Lepidocaryum tenue*).

Not all white-sand woodlands are restricted to Amazonia. *Restinga* encompasses the woody vegetation that covers the white-sand soils behind the dunes along the coast of Brazil. It once covered an almost unbroken stretch from Maranhão south to Santa Catarina, with patches of similar habitat reaching north to the mouth of the Amazon. In recent decades, however, it has become a fragmented and endangered habitat, much of it having been transformed into beach resorts and other coastal developments. *Restinga* varies from scattered tall thickets of dense shrubby growth on nearly pure white sand, within a few hundred metres of the coast, to taller, more diverse forest several kilometres inland. In general, *restinga* is sclerophyllous and stunted, with an understorey characterized by an abundance of terrestrial bromeliads. Although structurally similar to some of the Amazonian white-sand forests, the two are floristically unrelated, *restinga* being more similar to the nearby humid Atlantic Forest. Taller examples of this forest type are occupied by Plain Antwrens, Rufous-winged Antwrens (*Herpsilochmus rufimarginatus*) and Squamate Antbirds, and provide critical habitat for the globally threatened Unicoloured Antwren. *Restinga* is most specialized, and has the most impoverished avifauna, in the littoral zones immediately adjacent to the beach. Here, windswept and sand-blasted impenetrable thickets little more than a few metres high, and with a spiny understorey of cactus and bromeliads, are often isolated from one another by barren expanses of pure white sand. Relatively few bird species inhabit such extreme environments, but this is the home of the recently described Restinga Antwren, which is restricted to a small coastal strip in the state of Rio de Janeiro. Perhaps because of competitive release, the antwren is surprisingly common within its tiny range and endangered habitat.

The foregoing examples illustrate several points. At the most basic level, they provide several instances of the adaptive ability of antbirds to occupy highly specialized habitats. At the same time, they highlight the complexity and heterogeneity of low-

land Amazonian forests in general, and of white-sand forest in particular, while emphasizing that underlying soil mosaics can profoundly influence avian evolution and distributions. Finally, the discovery and rediscovery within little more than a decade of so many species, many of them from near centres of human population and in regions that have received considerable attention from ornithologists, demonstrates just how overlooked and under-investigated white-sand habitats have been.

Micro-habitats within forests create additional niches for birds, leading to greater overall species diversity. Patches of bamboo represent one of the most important micro-habitats in Neotropical forests. In lowland forests, the greatest diversity of bamboo-specializing birds occurs in south-eastern Peru, where A. W. Kratter recorded that, at single localities, as many as 19 bird species of a number of families can be restricted to *Guadua* bamboo thickets. Patches of *Guadua* are common in south-western Amazonia, eastwards through the Brazilian state of Acre, but become less common and more scattered farther east. Nonetheless, diverse communities of avian bamboo specialists have been documented in Brazil from sites in Rondônia, Mato Grosso and southern Pará, although, with few exceptions, these represent subsets of the more species-rich communities of Peru. Antbirds are conspicuous components of these communities. Of the many thamnophilids that occupy these lowland bamboo thickets, the Striated Antbird and the Manu Antbird are probably the ones most restricted to bamboo, seldom being found outside it. The Bamboo Antshrike (*Cymbilaimus sanctaemariae*) and Goeldi's and the White-lined Antbirds are also closely tied to bamboo, although, in addition, they occupy vine tangles or thickets in some floodplain-forests. Some populations of certain widespread species show much stronger affiliations with bamboo than do others. Thus, in some areas, the Chestnut-backed Antshrike, the White-shouldered Antshrike, the Ornate Antwren (*Myrmotherula ornata*), the White-flanked and Dot-winged Antwrens and the White-browed Antbird (*Myrmoborus leucophrys*) are found primarily in bamboo thickets, whereas in other parts of their ranges no such association is found. For many of these facultative users, the bamboo itself may be less important than the structure of the forest. Such birds are more dependent on light-penetrated gaps or forest edge, and in some regions bamboo species are the most common plants occupying these niches.

Bamboo specialization is not confined to antbirds living in the Amazonian lowlands. Indeed, bamboo diversity is highest in the Atlantic Forest of eastern Brazil, where a number of endemic

The genus *Hypocnemoides* contains two similar species, one of which is the **Black-chinned Antbird** of mainly northern Amazonia.

They are both streamside or lakeside birds, rarely found far from the water's edge, where they regularly join the small bands of insectivores that patrol this narrow strip of habitat.

Although their affinities are postulated to be with *Hypocnemis* and *Drymophila*, this relationship seems unlikely, given considerable dissimilarities in appearance and behaviour.

Both *Hypocnemoides* species build suspended pouch-nests, as do *Hypocnemis*, but their stereotyped body movements are different from the latter genus, as the tail is often held partially fanned and cocked slightly above the horizontal, and it is regularly flicked up. Further analysis is required to elucidate which are the true taxonomic neighbours of *Hypocnemoides*.

[*Hypocnemoides melanopogon melanopogon*, Guyana.

Photo: Doug Wechsler/VIREO]

genera combine with more widespread woody bamboos, such as *Merostachys* and *Chusquea*, to provide diverse bamboo communities from the coastal lowlands to the highest peaks of the Serra do Mar. Notable among the birds specializing on these bamboo thickets are the rare and endemic White-bearded Antshrike and several members of the genus *Drymophila*. Among the latter, all six of the Atlantic Forest species utilize bamboo to some extent, and four of them, the Ferruginous, Bertoni's, Ochre-rumped and Rufous-tailed Antbirds, are near-obligate specialists. Dusky-tailed Antbirds and some populations of the Scaled Antbird (*Drymophila squamata*) are also heavy users of bamboo, but can also be found in other, structurally similar habitats. Of the other members of the genus, the Striated Antbird, as mentioned earlier, is an obligate denizen of Amazonian thickets of *Guadua*, and the montane Long-tailed Antbird is a specialist of Andean bamboo thickets. In the Neotropics, Andean bamboo communities are second in diversity only to those of eastern Brazil. Accordingly, many Andean bird species are confined to patches of bamboo, particularly those of the widespread genus *Chusquea*. These Andean bamboos, however, occur primarily above the elevational limits of most thamnophilids and, of the Andean antbirds, only the aforementioned Long-tailed Antbird could truly be considered a bamboo specialist. Many formicariid ground-antbirds range much higher elevationally, and they, in turn, do exhibit varying degrees of bamboo specialization.

Vine tangles provide a less obvious micro-habitat upon which many antbirds specialize. The abundance of vine tangles varies greatly between forests. Lowland forests subject to pronounced dry seasons are usually more vine-rich than are either montane forests or those lowland forests in wetter regions. Although many bird species opportunistically forage or nest in the cover provided by vine tangles, others rarely stray far from them. Among the antbirds, most populations of the Fasciated Antshrike, the Spot-backed Antshrike, the Grey Antbird and the Dot-winged Antwren could be classified as vine specialists, and some other widespread species, such as the White-flanked Antwren, show a preference for vine tangles in parts of their range.

Similarly, a number of antbirds primarily inhabit treefall gaps within forest. Such openings in the forest canopy allow light to

penetrate to the forest floor, fuelling rapid colonization by pioneer shrubs, trees and herbaceous growth. The resulting dense profusion of new growth, combined with fallen branches and decaying logs, provides understorey insectivores with a wealth of foraging opportunities. The Undulated, Black-throated and White-shouldered Antshrikes, the Black Bushbird (*Neotantes niger*) and the Black Antbird (*Cercomacra serva*), along with the Warbling, Black-headed, Ferruginous-backed and Chestnut-tailed Antbirds, are all regular users of treefall light-gaps, with the first four of those seldom being found far from treefalls.

The Caura Antbird is a poorly known species found only in the western portion of the Pantepui region south of the Rio Orinoco in the Venezuelan states of Bolivar and Amazonas, and in extreme northern Brazil. It is known mainly from specimens collected on the slopes of scattered tepuis, many of which are strongly dissected and strewn with boulders and isolated blocks. The species has been studied only by K. J. Zimmer, in the Serrania de la Cerbatana of south-western Venezuela, where it occupies forested lower slopes of mountains that are strewn with large boulders, the biggest of which are up to 8 m tall and 15 m long. These boulders are covered with moss and ferns, and their tops and crevices are festooned with terrestrial bromeliads, cacti and bamboo. Many of them are topped with small trees, the gnarled roots of which drape over the rocks like tendrils, trapping leaf litter and organic debris. These rocks appear to be a critical component of the Caura Antbird's habitat, providing foraging strata that only the antbirds seem to exploit (see Food and Feeding). This species appears to have evolved as a specialist to occupy a rocky niche that is locally abundant in parts of the highly eroded Guianan Shield.

Many antbirds inhabit humid foothill forest above the lowlands, particularly in the lower Andean foothills, the lower slopes of the Guianan tablelands, and the mountains of the Atlantic Forest region of eastern Brazil. As previously noted, however, thamnophilid diversity drops off rapidly with increasing elevation. Parker and colleagues compiled a landmark database, published in 1996, of zoogeographical and ecological attributes of Neotropical birds. For each species they calculated the centre of abundance, an attribute defined as the "heart of a species"

**The Silvered Antbird** constitutes a rather unusual monospecific genus with unknown taxonomic affinities. It has a long thin bill, conspicuous pale pink legs and a curious side-to-side tail motion. It also occupies an unusual niche, being found mostly along the immediate edges of rivers, streams and oxbow lakes, where it commonly gleans aquatic and semi-aquatic insects and their larvae from partially submerged vegetation and from the water's surface. Unfortunately, no clues can be drawn from nest architecture, as its nest has never been described, despite the species being common throughout much of Amazonia. It is often located by its distinctive song, a long rising chipper, introduced by a single more emphatic note.

[*Sclateria naevia argentata*, Imuya Cocha, Sucumbios, Ecuador. Photo: Doug Wechsler/VIREO]

Like most antbirds, members of the genus *Percnostola* are highly sexually dimorphic, the males being largely black, and the females more or less rufous.

This dimorphism caused considerable confusion in the **White-lined Antbird** (male pictured above), as the first specimens taken were a young male (similar to the female) in 1914, followed by a series of adult females. On the strength of these specimens, the taxon was named the "Rufous-crested Antbird". When an adult male was finally collected in 1966, it was assumed to be a new species, and named the "White-lined Antbird".

Thus, for a decade, males and females of one taxon were thought to constitute two different species.

It was only when pairs were encountered in the field that the error was discovered. The White-lined Antbird pounds its tail down and then slowly raises it in a motion shared by the **Black-headed Antbird** (female pictured below), suggesting that these two forms may be closely related.

elevational distribution; the zone in which the bird species is most common". Of 196 thamnophilid species treated by those authors, 139, or 71%, were considered to have a centre of abundance termed "Lower Tropical", defined as "lowlands lower than 500 m in the tropics". For 29 species, 15%, the centre of abundance was thought to be "Hill Tropical", defined as "hills and lower slopes, 500-900 m, in the tropics", while nearly as many species, 26, fell into the "Upper Tropical" category, the "higher slopes, 900-1,600 m, in the tropics". Among the Thamnophilidae, only the Uniform Antshrike, which ranges to 2900 m, and the race *castanoptera* of the White-backed Fire-eye were categorized as being centred in the "Middle Montane" zone, defined as "mountains, middle range, 1,600-2,600 m". No thamnophilids were categorized as having a range centred in the "Upper Montane" zone, above 2600 m.

Although most antbirds are confined to humid forest environments, a surprising number have adapted to arid or semi-arid biomes. The semi-arid interior of north-eastern Brazil is

characterized by a thorny scrub formation known as *caatinga*. Growing on rocky, sandy or clay soils, at the mercy of intense dry seasons that may last for eight months, the *caatinga* is typified by drought-deciduous, often spiny trees and shrubs, particularly euphorbias and legumes, together with numerous stem succulents, including cacti such as the columnar *Cereus jamacaru* and various species of *Opuntia*, and abundant terrestrial bromeliads such as *Bromelia laciniosa*. Herbaceous plants are ephemeral, appearing mainly in response to the somewhat erratic seasonal rains, and grasses are few. The *caatinga* formation covers some 750,000 km<sup>2</sup>, and is far from uniform; in the most arid regions it may resemble shrub-desert, whereas at its peripheries and in more humid micro-climates it grades into deciduous dry forest. This environment is home to the Silvery-cheeked Antshrike (*Sakesphorus cristatus*), the subspecies *capistratus* of the Barred Antshrike, the Planalto Slaty Antshrike (*Thamnophilus pelzelni*), the subspecies *stagnus* of the Great Antshrike, the Black-bellied, White-fringed, Black-capped and

These males of the **White-bellied Antbird**, **Chestnut-backed Antbird**, **Sooty Antbird** and **Ferruginous-backed Antbird** illustrate the range of variation found within the genus *Myrmeciza*. It contains a total of 20 medium-sized to large species with broadly similar morphology; they either inhabit the lower storey or are partially terrestrial. As our understanding of antbird relationships improves, it is becoming increasingly clear that this genus is polyphyletic. In other words, some of its members are likely to be less closely allied to each other than they are to species currently placed in other genera, including *Myrmorchilus*, *Pyriglena*, *Rhopornis*, *Myrmoborus*, *Gymnocichla*, *Sclateria* and *Pernostola*.

Caatinga Antwrens, as well as the Pectoral Antwren (*Herpsilochmus pectoralis*), and the Stripe-backed Antbird.

In slightly elevated portions of south-central Bahia and north-eastern Minas Gerais, the *caatinga* grades into a stunted, dry deciduous forest known regionally as *mata-de-cipó*, or "vine forest". This forest is characterized by a low canopy, often 12 m or less, a mid-storey of small trees and shrubs covered with vines and bromeliads, and an understorey dominated by large patches of the terrestrial bromeliad *Aechmea*, some of which reach nearly 2 m in height. This unique and endangered habitat is occupied by two equally unique and globally threatened antbirds, the Narrow-billed Antwren and the Slender Antbird, as well as by many of the more generalized *caatinga* species listed above. The Slender Antbird is an extreme specialist, concentrating much of its foraging, and possibly its nest-building, within the thickets of *Aechmea*.

Antbirds occur in other xerophytic formations, although none of these can boast of the same levels of thamnophilid diversity as that found in the *caatinga*. The *caatinga* is connected by a corridor of mostly open habitats across the Brazilian Planalto

Central to another arid scrubland, the Chaco, which in the most inclusive terms takes in portions of southern Bolivia, western Paraguay and northern Argentina. The Chaco is a mostly flat, gradually sloping alluvial plain, characterized by clay soils, and by highly seasonal and irregular precipitation patterns, with most rain falling during the austral summer, and intense dry seasons that may persist for up to nine months. It is driest in the west, where the mean annual precipitation is about 35 cm, and where the landscape is dominated by dense, stunted thorn-scrub 5-10 m high, with an understorey characterized by abundant cacti and terrestrial bromeliads. The Chaco antbird community is virtually a smaller subset of that of the *caatinga*, with Great and Barred Antshrikes, Black-bellied Antwrens and Stripe-backed Antbirds, as well as, locally, Giant Antshrikes, Variable Antshrikes (*Thamnophilus caerulescens*) and Rusty-backed Antwrens.

Bordering the southern Caribbean, the extreme northern part of Colombia and north-western coastal Venezuela encompass another arid region with a variety of habitats ranging from shrub-desert to taller thorn-scrub and deciduous dry forest. Antbird di-

versity here is extremely limited, but includes the endemic Black-backed Antshrike and the race *pulchellus* of its congener, the Black-crested Antshrike. Another member of the genus *Sakesphorus*, the Collared Antshrike, represents the Thamnophilidae in the drier habitats of the Tumbesian region of south-west Ecuador and north-west Peru, where it is common in dense algarrobo (*Prosopis*) riparian woodland and lighter thorn-scrub, as well as in seasonally dry *Bombax* forest. This species also occupies equally arid habitats in the Marañón Valley of north-western Peru, where the cordilleras to the east have created a giant rainshadow, and the valley floor is vegetated by deciduous dry forest and desert scrub dominated by *Prosopis*, *Acacia*, abundant cacti and herbaceous shrubs.

A welcome addition to the family, described as recently as 1995, is the Marsh Antwren of south-east Brazil, which inhabits littoral marshes dominated by bulrush (*Typha*) and club-rush (*Scirpus*), with grasses and scattered shrubs. The most ecologically similar species are the closely related Rusty-backed and White-fringed Antwrens, which occupy marshy, grassy savanna and *campo* habitats through much of northern South America, but those two are not so restricted to a particular type of habitat as is the Marsh Antwren.

Diversity of habitat use among different populations is rather a common feature of antbirds. Although some geographically wide-ranging thamnophilids occupy essentially the same habitats throughout their ranges, others exhibit striking shifts in habitat from one population to another. One of the most extreme examples involves the largest member of the family, the Giant Antshrike. Where it is most common, in the Atlantic Forest portion of its range, this species occurs in humid evergreen forest, from sea-level up to wet, elfin ridgetop forest, usually with extensive bamboo in the understorey. In the Andes, the association with bamboo is less pronounced, and the species occupies mostly dense growth along the margins of ravines and streams in montane forest. At lower elevations in Bolivia, Paraguay and Argentina, Giant Antshrikes are found only in dense thickets of thorny bushes and terrestrial bromeliads in xerophytic, stunted Chaco woodland, a far cry from the fog-shrouded, wet forest which they inhabit elsewhere. In most of Amazonia, the Blackish-grey Antshrike occupies islands and, to a lesser extent,

riverbanks in the dense understorey of seasonally flooded *várzea* and *igapó* forest. In French Guiana, however, the race *kulczynskii* is found mostly in the middle stages of coastal mangroves, although it also occurs along some rivers near the coast. In contrast, in eastern Colombia and south-western Venezuela, the subspecies *cinereoniger* is most common in dense, stunted savanna woodlands which are seasonally flooded and which grow on white-sand soils. As a third example, the nominate, western race of the Amazonian Antshrike (*Thamnophilus amazonicus*) is almost entirely confined to riverine viny borders and gaps in *várzea* and *igapó*. In south-central Amazonian Brazil, the subspecies *obscurus* is more widely distributed in forest edges and openings, inside viny forest and dense second growth, and in dense stands of *Guadua* bamboo in both *terra firme* and transitional forest. Farther east, the race *paraensis* occurs primarily in second growth and gaps of *terra firme* and *igapó* forest, but is rarely found in the *várzea* favoured by nominate birds. In the Guianan region, the subspecies *divaricatus* occupies liana-rich portions of *terra firme* forest, open forest near tepui summits, and river edges. Perhaps the most divergent population of the Amazonian Antshrike is the subspecies *cinereiceps* of the upper Rio Negro region, which is found in dense, stunted woodland growing on white-sand soils and in shrubby borders of taller, predominantly white-sand forest.

Not all cases of regional habitat shifts by thamnophilids involve antshrikes. Across its extensive range, the White-fringed Antwren, as noted above, occupies the understorey and mid-storey of a variety of habitats. In some areas this species occupies several habitats, but most regional populations tend to be habitat-restricted. In southern Venezuela, south-east Colombia and northern Brazil north of the Amazon, the subspecies *orenocensis* and *rufiventris* are generally confined to either white-sand *campina* woodland or young second growth. In parts of the Guianas, nominate *grisea* is a mangrove bird, whereas, south of the Amazon, it occupies humid second growth and riparian vegetation in the Amazon Basin, *restinga* scrub on white-sand soil in coastal north-east Brazil, and tropical deciduous forest and *caatinga* scrub in interior north-east Brazil. In northern Venezuela, *intermedia* is more of a generalist, utilizing several habitats within the same region, including thickets along deciduous-forest bor-

#### The Spot-backed Antbird

is one of a stunning trio of similar species in the genus *Hylophylax*, the others being the Spotted Antbird (*H. naevioides*) and the Dot-backed Antbird (*H. punctulatus*). Both sexes of these three species, but especially the males, are dinky, boldly marked gems of the understorey. They share tonally similar songs, and a habit of flicking the tail upward then letting it fall slowly. Pairs of Spot-backed Antbird tend to forage independently, rarely accompanying antswarms, and generally spurning the company of mixed-species understorey flocks.

[*Hylophylax naevius*.  
Photo: J. S. Dunning/  
Ardea]

The classic antbirds are the ant-followers, and one of the classic ant-followers is the **White-plumed Antbird**. This sexually monomorphic species is one of the thamnophilids most regularly found in attendance at antswarms across its broad Amazonian range. With its unique facial ornaments and sly charisma, it is a joy to watch, especially when small groups are working a swarm. At such times, White-plumed Antbirds are constantly shifting position, vigilant, opportunistic, and sometimes quite tame. Being relatively small, they are subordinate to, and systematically attacked by, most other ant-followers. They rely on their extreme speed and agility to infiltrate the innermost zones of a swarm, to snatch prey from larger species, and to retreat just ahead of the inevitable attack. They return repeatedly to productive spots, despite being constantly assaulted.

VIREO]

ders and seasonally flooded savanna, taller deciduous thorn-scrub, gallery-forest borders, second-growth scrub and mangroves. Molecular analyses and studies of vocalizations and other behavioural characteristics are needed in order to determine whether these taxa should be maintained as subspecies, or whether they meet the criteria required for recognition as biological species (see Systematics).

Most of the preceding examples involve habitat shifts among subspecies, each of which has its own preferred range of habitats. In contrast, some species or subspecies are habitat generalists throughout most of their range, but with one or a few populations of the same taxon exhibiting pronounced specialization or restriction to a single habitat. For example, the White-flanked Antwren is something of a habitat generalist throughout much of its range, occupying the understorey and mid-storey levels of humid evergreen forest and second-growth woodlands, including *terra firme*, transitional forest, *várzea* and *igapó*. In Brazil, however, populations of the nominate race in northern Mato Grosso are found primarily in stands of *Guadua* bamboo, whereas populations of the same race in south-western Pará, south-eastern Amazonas, north-east Rondônia and parts of Amapá are confined to river-edge forest and are seldom found more than 100 m from the water's edge. Similarly, where the Ornate Antwren occurs in the absence of closely related congeners, it is widely distributed in humid evergreen forest. In regions that are also inhabited by closely related antwrens which employ dead-leaf foraging (see Food and Feeding), it is usually, although not always, restricted to particular habitats such as extensive *Guadua* bamboo thickets within forest, vine tangles at forest edge or in light-penetrated gaps, or narrow bands of forest and second growth immediately bordering river edges.

Both intra-taxon and inter-taxon habitat shifts are exhibited by the various populations of Barred Antshrikes. This species inhabits mainly thickets and shrubby borders at forest edge, often venturing into cultivated areas, gardens and parks with thickets, hedgerows and trees. It occurs in both arid and humid regions, and in many parts of its range is something of a habitat

generalist. In central and western Amazonia, however, the subspecies *radiatus* is almost exclusively a river-island bird, while in north-east Brazil the subspecies *capistratus* is largely an inhabitant of deciduous *caatinga* woodland. Regardless of subspecies, populations in savanna regions are usually restricted to gallery-forest edge or isolated areas of savanna woodland, whereas populations on islands where other *Thamnophilus* antshrikes are absent, such as Tobago and the Panamanian Isla Coiba, occur in almost all micro-habitats, ranging up to the crowns of trees.

In some cases, these geographical shifts in habitat are doubtless associated with underlying genetic differences between populations that will eventually be shown to be biologically distinct species. In other cases, they may be found to reflect a certain amount of behavioural plasticity. Which habitat a species occupies in a given region may be determined largely by competitive interactions with closely related congeners or ecological counterparts, or by competitive release from such interactions. Conversely, it may depend as much as anything on historical patterns of habitat expansion and contraction, combined with chronologies of ancestral colonization. Present-day patterns may be artefacts of whichever species were the first to radiate into vacant niches created by climatic dry-wet oscillations and the resultant habitat expansions and contractions. Once the first colonizing species establishes a toehold, ecologically similar competitors attempting to colonize may be forced to contract or expand their habitat-utilization patterns accordingly.

Because the bulk of antbird species are forest birds, they tend not to adapt well to man-altered habitats. Exceptions include the Barred, Lined, Bar-crested and Black-crested Antshrikes, all of which are known to occupy, at least regionally, not only highly degraded woodland and second growth, but also shrubby borders of city parks and gardens and even suburban yards. The Great Antshrike and several members of the genera *Cercomacra* and *Formicivora* are able to exploit highly degraded second-growth habitats, particularly where old fields or plantations have been allowed to regenerate. Tufted Antshrikes in eastern Brazil regu-

Members of the genus *Gymnopathys*, including the **White-throated Antbird**, are amongst the smallest "professional" ant-followers. When they are alone they tend to feed like larger species, pausing for prolonged periods on low, prominent perches close to the epicentre of the antswarm. In the presence of "bare-eyed" species of the genera *Phlegopsis* or *Rhegmatorhina*, they are usually supplanted, and forced to the periphery, where they flit about more rapidly, and hunt from higher branches.

[*Gymnopathys salvini*,

VIREO]

larly inhabit the tangled understorey of regenerating orchards and banana plantations, as does the globally threatened Black-hooded Antwren (*Formicivora erythronotos*). Tufted and Variable Antshrikes and Serra Antwrens have all been found to occupy eucalyptus (*Eucalyptus*) plantations in which dense herbaceous vegetation, including bamboo, has been allowed to regenerate in the understorey. In Amapá, Brazil. White-bellied Antbirds have been recorded in the understorey of commercial pine (*Pinus*) plantations bordering *cerrado*, where thickets of terrestrial bromeliads have been allowed to grow beneath the pines.

### General Habits

Antbirds are, without exception, diurnal. So far as is known, they roost in trees or shrubbery, and do not use dormitory nests or holes as nocturnal shelters. Of the few published accounts of the roosting behaviour of thamnophilids, the most detailed is that of A. M. Young's observations of a male Spotted Antbird in the Caribbean lowlands of Costa Rica. The bird was discovered sleeping 3.2 m above the ground on a horizontal branch of a small rubiaceous tree. Young checked the site on 46 nights between 3rd February and 30th May, and on 39 of those found the bird roosting in the same tree, 84% of the time on the same branch. On the other seven nights, the antbird could not be located, despite a flashlight check of all similarly sized trees within 30 m of the original roosting tree. The time of the antbird's arrival at the roosting site was very regular, varying only from 17:47 to 18:12 hours, regardless of weather conditions.

These observations fit well with those by K. J. Zimmer of a female Spot-backed Antbird in Napo, Ecuador. This individual was found roosting on an exposed section of a horizontal branch of a slender understorey sapling 3-4 m above ground. Flashlight checks revealed its presence on the same branch on 15 consecutive nights, and on each following morning 30 minutes before dawn. As dawn approached, the first songs from a nearby male Spot-backed Antbird always elicited a series of loud "chip" notes from the roosting female, which immediately left the perch to join her presumed mate.

Little has been recorded of the loafing and comfort behaviour of the majority of antbirds. Most of what is known comes

from Willis's studies of obligate ant-following species (see Food and Feeding). Because of the superabundance of foraging opportunities presented by army-ant swarms, ant-following thamnophilids may have more time available for comfort behaviour. Antbirds which appear insatiable upon arriving at a swarm gradually slow down and begin to ignore all but the largest prey. During intervals between sightings of large prey items, they yawn, scratch, preen, egest waste material, and often retire to the protective cover of a vine tangle or thicket in order to loaf and preen. Antbirds which do not follow ants may not have the luxury of abundant time in which to indulge in these activities, and may need to devote a greater percentage of time to foraging. P. J. Marcotullio and F. B. Gill recorded the daily movements of a pair of colour-ringed Chestnut-backed Antbirds in Costa Rica; they found that the birds spent 93% of their time in foraging, and that the time spent at rest, described as sitting quietly, with intermittent preening, was almost entirely restricted to the two two-hour periods between 09:00 and 13:00 hours.

Loafing antbirds usually occupy horizontal perches, and visibly fluff their feathers, particularly the ventral and rump feathers. This may be a mechanism for trapping body heat, so that the bird expends less energy in maintaining its body temperature when resting. Loafing is often followed by preening and stretching. Preening birds alternately fluff different feather groups while running feathers between the tips of the mandibles. "Underwing-looking", in which a bird stretches one wing laterally and then inspects the wing-linings for several seconds, has been noted for several species of antbird. Head-scratching is most often accomplished by lowering one wing and then raising the foot over it, known as the indirect method of scratching.

Mutual grooming, or allopreening, has been noted for several species. Typically, one bird takes a perch next to its mate, and then ruffles the feathers of the head and neck as it bows forwards with the bill pointed downwards. The individual being groomed remains immobile in this head-down posture, in a nearly catatonic state, as its partner picks and nibbles at the feathers of the nape, head and face, as well as at the bill; the body feathers are usually not groomed. This solicitation-for-grooming posture, or ones very similar to it, has been noted for species in such diverse genera as *Thamnophilus*, *Cercomacra*, *Hylophylax* and

The genus *Rhegmatorhina* is a well-defined group of species, all of which are "professional" ant-followers.

The **Bare-eyed Antbird** is typical of this group in its unmarked upperparts and the large pale area of bare skin set in a dark face. This periorbital patch produces a startling goggle-eyed effect. It has been speculated that it might function as the "iris" in an eyespot design, making the bird seem larger than it actually is, and thus scaring away potential predators or frightening competitors at the swarm. Whether these thickened patches of skin also provide protection against the bites of ants is not known.

[*Rhegmatorhina gymnops*, Cristalino Jungle Lodge, Alta Floresta, Mato Grosso, Brazil. Photo: Edson Endrigo]

Another duo of "professional" ant-followers are the bare-eyes (*Phlegopsis*), both of which have large pinkish patches of skin around the eye, and both of which show plumage that is primarily blackish and russet. Because of its large size, the **Black-spotted Bare-eye** is usually dominant at antswarms; the only two taxa to which it will defer are its congener, the Reddish-winged Bare-eye (*P. erythroptera*), and the Pale-faced Antbird (*Skutchia borbae*), both of which are slightly more bulky.

[*Phlegopsis nigromaculata*.  
Photo: J. S. Dunning/  
Ardea]

*Gymnophithys*. Zimmer has noted that allopreening is a common response to tape playback among mated pairs of some *Cercomacra* species. When responding to playback of male-female duets, females of the Bananal, Mato Grosso, Manu and Rio de Janeiro Antbirds frequently join their mates on a branch and assume the solicitation posture. The bouts of allopreening that follow are nearly always one-sided, with the female as the recipient. Female Bananal Antbirds that have been visually separated from their mates during bouts of tape playback, on being reunited, frequently nibble at the mate's bill for several seconds. Thus, mutual bill-nibbling and allopreening of females by males appear to reinforce pair-bonds in response to potential trespassing by conspecifics.

Stretches usually involve several stereotyped motions, for which Willis used a specific terminology. These include "full side stretches", involving stiff extension of the leg, wing and tail on one side of the body; "two-wing stretches", in which the bird leans forwards while extending both wings above the back; and "toe standing", whereby the bird stands tall, with the foot extended, as it flexes the toes and supports itself on the tips, rather than on the "soles" of the feet.

At times, antbirds regurgitate fragments of chitinous insect exoskeletons and other indigestible materials. These are sometimes compacted into pellets, but more often are not. Excreta are typically white and mostly fluid, and are dropped frequently.

More than 200 bird species, of many families, have been recorded as systematically rubbing live or crushed ants, beetles, centipedes (Chilopoda) and other arthropods through their feathers. These potential prey items are seized with the bill, chewed and shaken repeatedly, and brushed and rubbed through the wings, tail and body feathering, before being eaten or discarded. This behaviour, termed "anting", is generally believed to play a beneficial role in feather maintenance, either by relieving skin irritation related to moult or by reducing the numbers of feather mites, lice and other ectoparasites, or in some cases by performing both functions. Willis has suggested that, alternatively, anting could be connected with foraging behaviour, in which distasteful secretions of the arthropod are rubbed off prior to the food being swallowed. He further suggested that, among obligate ant-following members of the family, anting may be practised mainly by hungry subordinate individuals, which are reduced to catch-

ing less desirable and frequently noxious prey on the fringes of swarms. Antbirds usually wipe the bill vigorously on limbs after anting. Among the *Thamnophilidae*, anting has been reported for five species, the Spotted, Bicoloured, Lunulated, White-breasted and Ocellated Antbirds.

In general, the antbirds, or the majority of the forest-dwelling understorey species, at least, are seemingly photophobic, shunning even small patches of sunlight. A few species have been recorded, rarely, as "sun-bathing", in which the bird pauses in a sunlit spot, with feathers ruffled, wings and tail variably outstretched, and often with one eye turned towards the sun. Such poses are seldom held for more than a minute or two before the bird snaps out of its nearly trance-like state, sleeks its feathers, and moves back into the shade.

Many antbird species have been reported to bathe in shallow pools or along forest streams. Bathing can take place at any time of the day, but may be most frequent in the late afternoon. Bathing antbirds typically stand in shallow water and repeatedly lean forwards and dip the head and body several times while holding the wings and tail at least partly outstretched. After a thorough wetting, the bird usually flies to a horizontal perch in nearby cover and preens vigorously. Antbirds of more than one species which have been attending the same ant swarm (see Food and Feeding) often bathe side by side in the late afternoon at the same forest pool, commonly exhibiting the same types of supplanting, displacement and competitive behaviour as those which accompany their foraging. Arboreal species of the mid-storey, subcanopy and canopy seldom descend to the ground to bathe, but instead bathe in water trapped within the leaves of bromeliads, in hollows of broken limbs or in similar situations high above the ground.

In response to potential danger, some antbirds crouch and freeze, remaining totally motionless for up to several minutes at a time. This behaviour may be most developed among the more terrestrial species, such as the Banded Antbird and the Wing-banded Antbird, both of which have been observed by Zimmer to crouch and freeze for up to ten minutes in response to the observer's presence. In contrast, Willis found freezing to be sustained only briefly by Bicoloured Antbirds and other *Gymnophithys* species, as well as by *Rhegmatorhina* antbirds, among which genera it is generally accompanied by a vocaliza-

The genus *Phaenostictus* is related to the *Phlegopsis* bare-eyes. Indeed, it replaces them in the humid lowland forests of southern Central America and in the Chocó region on the Pacific slope of the Andes in Colombia and Ecuador. The sole occupant of this genus, the **Ocellated Antbird**, is a large and impressive species that dominates ant-following assemblies throughout its distribution. It is often difficult to find because it occurs at low densities and occupies large home ranges, often as much as 1500 m across. Apart from the Black-spotted Bare-eye (*Phlegopsis nigromaculata*), it is the only antbird known to exhibit long-term bonds between parents and offspring. These bonds result in small family groups developing around a successful pair: young males and their mates are tolerated for several years, thus forming patrilineal clans that fragment or fuse as food supplies dictate. Young females typically remain on their natal territories for only one year, after which they disperse to mate outside the clan. The largest clans can contain eight or more individuals, all of which co-operate to defend the territory against rival clans. During disputes over land, clan members bunch together, shoulder to shoulder, in a remarkable display of territorial solidarity.

[*Phaenostictus mcleannani*, Soberania National Park, Panama.  
Photo: Marie Read]

Many species of antbirds, particularly males, have white interscapular patches which are normally concealed beneath mantle feathers. During agonistic displays, however, the overlying feathers are parted and the white feathers are flared as part of an aggressive signal. Set against the shadows and dull hues of the dimly lit understorey, the visual effect of a bright white interscapular patch is striking, as shown here by a male **White-backed Fire-eye**. Most of the time, when this species is relaxed or foraging, the patch is almost invisible.

[*Pyriglena leuconota similis*,

tion that he termed "keening", a low-amplitude, faintly whistled "keee". Willis found keening to be a more common response to potential danger when members of a mated pair were together, with the vocalizations sometimes spreading through a flock of birds at an ant swarm and causing all birds to freeze, at least temporarily. The usual stimulus for both keening and freezing seems to be potential but unlocated or distant danger, often signalled by a distant alarm call from some other bird, or by a sudden loud noise.

When danger is close, or is located, many antbirds shift to a mode that Willis has termed "panicking". Panicking is usually signalled by a burst of excited "chip" calls and abrupt flights as the birds dive for cover, where they may continue to call loudly at sporadic intervals. Among the obligate ant-followers (see Food and Feeding), panic often induces a general state of hyperactivity: the birds leap from one perch to another, pitch and yaw on their perches, expressively raise and lower the crown feathers, this being especially true of *Rhegmatorhina* species, and move their wings and tail in species-specific motions (see below). Sudden flights by one individual can induce a "stampede" effect, in which other antbirds explode into frenzied flight.

At other times, the presence of a potential predator may elicit a mobbing response rather than a flight response. Obligate ant-following thamnophilids often respond to the presence of mammals, including humans, with angry, low-frequency "chirring" calls (see Voice). These are often delivered with the tail fanned and the wings held slightly drooped and spread, making the bird appear bigger than it really is. *Gymnopithys* and *Rhegmatorhina* antbirds frequently extend the head and neck, thus presenting the bare facial area to the object of mobbing. While thus engaged, they may swing around and around on a vertical perch, staring directly at the offending mammal. Willis speculated that the large pale "goggle" of the various *Rhegmatorhina* species, being set around a dark eye and surrounded by an otherwise dark face, could, in the gloom of the forest interior, resemble a large eye of a cat or some other predator, and could be effective in frightening some animals away; he noted that the bare patches are particularly prominent when the birds are mobbing and when they are displaying to conspecifics. Willis also noted the cause of "chirring" by Bicoloured Antbirds on 30 occasions, excluding hundreds

of others when the birds chirred at him. Only twice were these calls directed at other bird species, once at a Squirrel Cuckoo (*Piaya cayana*) and once at a Crimson-crested Woodpecker (*Campephilus melanoleucos*). They were directed at coati-mundis (*Nasua narica*) nine times, at tayras (*Eira barbara*) seven times, at capuchin monkeys (*Cebus capucinus*) four times, at humans twice, and once each at an anteater (*Tamandua tetradactyla*), a brocket deer (*Mazama americana*), an ocelot (*Felis pardalis*), a jaguarundi (*Felis yagouarundi*) and feral pigs (*Sus*). In contrast, White-plumed Antbirds directed chirring calls towards mammals, predatory birds, both conspecific and other thamnophilid competitors at ant swarms, and even towards large saturniid moths. Antbirds may shift back and forth from panicking to mobbing, the latter being more persistent from individuals or pairs which have a nest or fledged young nearby.

The presence of a snake often elicits more aggressive mobbing behaviour, in which antbirds not only give persistent loud calls of alarm, but also seemingly attempt to drive the snake from the area by physically harassing it. Zimmer has seen Rufous-winged Antwrens, Grey Antbirds and Dusky Antbirds (*Cercomacra tyrannina*) following arboreal snakes through vine tangles, while repeatedly fluttering at the reptile and giving continuous alarm calls. Similarly, some antbirds also aggressively mob pygmy-owls (*Glaucidium*). In Brazil, for example, the Glossy, Great and Barred Antshrikes, the Planalto Slaty Antshrike, the Plain Antvireo, the Black-capped, Pectoral and Large-billed Antwrens and the Mato Grosso Antbird have all been recorded mobbing Ferruginous Pygmy-owls (*Glaucidium brasilianum*).

Many thamnophilids display stereotyped body motions, involving especially the wings and tail, which are characteristic of the species, of a particular species group, or of an entire genus. For example, many species of antbird habitually "wing-flick" by partially opening and closing the wings rapidly and repeatedly. Tail movements vary in more complex ways, including direction, whether vertical or horizontal, as well as speed, fluidity, the direction of initial movements, the depth or range of movements, and so on. The tail may be moved at the same speed throughout the motion, or one part of the action may be faster than another, and movements can be smooth or jerky. Some species, such as

The **Scale-backed Antbird** is probably misplaced in the genus *Hylophylax*. It differs from its congeners by nature of its plainer body plumage, its tail actions and its loudsong - a series of long, upwardly-inflected, high-pitched whistles, unusual amongst antbirds, but quite similar to the whistles of piping-guans (*Pipile*). This female and male illustrate the propensity of many antbirds to perch laterally, clasp narrow stems, or using their sharp claws to hold on if the stem is too broad to clasp.

the Black-headed, White-lined, Slender and Bare-crowned Antbirds, the fire-eyes and several members of the genus *Myrmeciza*, perform "tail-pounding", which involves pounding the tail downwards quickly and emphatically and then slowly raising it. Others, including all members of the genera *Gymnopithys* and *Rhegmatorhina*, flick the tail rapidly upwards and then slowly lower it. Other variations include "tail-jerking", in which the tail is first lowered slowly, then jerked abruptly upwards; the "vertical twitch", when the tail is moved rapidly up and down; the "horizontal twitch", with the tail being moved rapidly from side to side; the "vertical wag", a slow and even up-and-down movement of the tail; and the "horizontal wag", a slow and even movement of the tail from side to side. Less common tail motions include the rapid, shallow "quivers" exhibited by most members of the "slaty antshrike complex", and the jerky, side-to-side swinging of the tail demonstrated by Silvered Antbirds and Yapacana Antbirds.

Many thamnophilids exhibit still different body actions when singing, often involving a degree of synchronicity between the motions of the wings, tail and/or body and the notes of the song. Such synchronicity of voice and movement reaches its zenith in the "barred group" of *Thamnophilus* antshrikes, in which a singing bird leans forwards and bows and bobs its entire torso while simultaneously wagging its fanned tail, all in perfect synchrony with the rhythm of the song.

Willis was the first to draw attention to the stereotyped tail and wing motions of antbirds, and to their potential as phylogenetically informative characters (see Systematics). He also documented a wide array of postures and body motions associated exclusively with intraspecific agonistic interactions among the various obligate ant-following species of the genera *Pyriglena*, *Pithys*, *Gymnopithys*, *Rhegmatorhina*, *Phlegopsis*, *Skutchia* and *Phaenostictus*, as well as among some regular ant-followers such as the Black-headed and Scale-backed Antbirds. Intraspecific signals, both physical and vocal, of dominance and submissiveness are probably more highly evolved among obligate and regular ant-followers than in other members of the family, as such mechanisms allow the relaxation of strict territoriality and enable multiple pairs of conspecifics to gather at a single ant swarm (see Food and Feeding). Unfortunately, published descriptions of such agonistic displays, postures and body motions are lacking for the majority of thamnophilid species.

## Voice

For many fieldworkers, the sounds of antbird loudsongs, each distinctive in its proclamation of species identity, serve to epitomize tropical New World forests, and they are especially welcomed by those who wish to locate antbirds and study them. The antbird syrinx is rather basic in construction when compared with that of the oscine songbirds (see Systematics, Morphological Aspects), and the songs of thamnophilids are correspondingly uncomplicated, usually consisting of series of simple notes. Nevertheless, the variety of ways in which notes are shaped into clear whistles or raspy sounds, slowed down, or speeded up into trills seems endless. Birds living in dimly lit habitats can be expected to employ vocalizations extensively for communication, and the antbirds are no exception. Most antbirds can be heard throughout the day and throughout the year, and they seem to be asking and answering such questions, in anthropomorphized form, as "Who are you?" and, especially, "Where are you?", or making statements to the effect "This patch is mine!"

Antbirds deliver a variety of vocalizations, but the function or, more likely, functions of each are poorly understood. Most apparent in the field is the loudsong, a term coined by Willis, referring to the ringing series of notes that is more broadly described as song, in other words, multi-noted vocalizations delivered in a stereotyped pattern. Loudsongs are heard in a variety of contexts, from which their functions may be deduced, although with caution. Some species, such as the Plain-winged and Mouse-coloured Antshrikes, give loudsongs when the mates are foraging at a distance from one another; usually, the male sings first and the female answers, suggesting that loudsongs may be used by pair-members to maintain contact, although, as noted below in the discussion of duets, responsive singing may also reflect joint territorial defence. Other species, such as the Cinereous and Bluish-slate Antshrikes, leaders of understorey mixed-species flocks (see Food and Feeding), rarely deliver loudsongs except when neighbouring flocks meet at a common boundary, more clearly suggesting a purely territorial function. Sometimes, the use of loudsongs to proclaim territories appears even more obvious, as exemplified by a male Black-crested Antshrike in the Venezuelan llanos observed by Isler and Isler to make a rapid traverse of its territory every day at dawn, stopping every 5-10 m or so to deliver a loudsong or two. Although antbirds often de-

liver loudsongs when neighbouring pairs of the same species approach one another near their mutual territorial boundary, other types of vocalization are also given in this context.

Males and females of most thamnophilid species deliver similarly patterned loudsongs. Despite assertions made by some authors, it is not always the case that, when the two sexes give near-identical loudsongs, that of the female is constantly higher-pitched than the male's. Although females of some species do deliver their loudsongs at a higher pitch than that of their mates, females of others sing at the same pitch as the male, and still others at a lower pitch. Sometimes, there is a sexual difference in change of pitch; for example, the notes of the male Uniform Antshrike's loudsong are maintained at the same pitch, whereas the female's notes typically rise in pitch. Most often, female loudsongs are shorter in duration, with fewer notes, than those of the male; again, however, there are exceptions, such as the female Ochre-rumped Antbird, the songs of which contain many more notes than do those of the males.

Typically, the female's loudsong follows the male's, although her timing of delivery varies among species, a character that may be significant for phylogenetic studies. In some genera, such as the *Thamnophilus* antshrikes, males and females seem to deliver their loudsongs without temporal synchronicity, the female responding to the male after a somewhat variable time interval. In other genera, such as the *Hypocnemis* antbirds, the female starts her loudsong just before the male's ends, and, because this occurs in a constant stereotyped pattern, these songs are considered duets. In more complex duets, such as those exhibited by the Jet Antbird and certain other *Cercomacra* species, vocal cues are given by the female during the course of the male's loudsong which cause the male to change his vocalization and begin a duet. In another group of *Cercomacra* antbirds, exemplified by the Blackish Antbird (*Cercomacra nigrescens*), male and female loudsongs overlap in timing of delivery but differ so greatly that one would hardly guess that they were given by the same species, except that the female begins her song while the male is singing. Ferruginous-backed Antbirds also have distinct male and female songs, but without overlap in delivery, making the connection more difficult. Nevertheless, the usual case is, as with

most *Drymophila* and some *Myrmeciza* antbirds, that the male and female songs are similar structurally but with just enough variation in pace, pitch, number of notes and similar parameters to be recognizable by sex.

It is unclear whether duets are a manifestation of co-operation and bonding between pair-members or an expression of joint territorial defence. At face-to-face conflicts between conspecific neighbours at territorial borders, males confront one another and females respond to females, but in these circumstances, as mentioned above, other types of vocalization besides loudsongs may be used by both sexes.

The term "loudsong" is used to distinguish different vocalizations that fit the general definition of a song. Since antbirds are typically paired for life (see Breeding), it is a rare event when an unpaired individual with an established territory delivers a song to advertise for a mate. In a pioneering experiment involving paired Dusky Antbirds, E. S. Morton temporarily removed each sex in turn from the territories. After removal of the mate, the remaining individual delivered a somewhat different song: males accelerated the pace of their normal loudsongs, a trill, into a long rapid twitter, and females typically combined the trill of the male with the rising series of whistled notes characteristic of their own normal loudsongs. Morton termed these vocalizations "courtship songs". From the standpoint of using loudsongs in systematics, it is useful to record that the structure of the notes used in Dusky Antbird courtship songs is essentially the same as that in loudsongs, even though other vocal characters are modified.

Some antbirds deliver more than one loud, stereotyped vocalization, and in such cases it may be difficult to decide which should be considered a loudsong. For example, both sexes of the Guianan Streaked Antwren and the Amazonian Streaked Antwren deliver a stereotyped rattle-like series of notes, as well as a more pleasant, stereotyped series of whistles that rises and falls in pitch. Isler and colleagues, in an analysis of species limits (see Systematics), considered the rattle-like series to be the loudsong; this was because loudsongs of two closely related species, the Pacific Antwren (*Myrmotherula pacifica*) and Cherrie's Antwren, also consist of a rattle-like series, and these

Antbirds occur almost wherever wooded habitats are found in South and Central America. Unlike the Furnariidae, however, they are absent from forests at high altitudes (e.g. Polylepis), and at high latitudes (e.g. Nothofagus). Some species, including the **Giant Antshrike**, occupy different habitats in different portions of their ranges. In south-east Brazil, for example, it occurs in humid forests from sea-level to the high mist-shrouded ridges of the Serra do Mar. Far to the west, in the Andes of northern Argentina and Bolivia, it is restricted to dense montane forests. In the intervening lowlands, however, it inhabits the stunted woodlands of the semi-arid Chaco.

[*Batara cinerea cinerea*,  
Fazenda Intervalles,  
São Paulo, Brazil.  
Photo: Edson Endrigo]

Antshrikes in the "barred group" of the genus *Thamnophilus* usually shun the interior of tall forest. Although some will enter low-stature forest, particularly where it is dry or more tangled, most occupy bushy country or forest borders. In the eastern portion of its range, the **Rufous-capped Antwren** is typical in being a bird of low, dry scrub, brushpiles, patches of low woodland and impenetrable thickets on brushy grasslands. Its habitat preferences are variable, however. It occurs from sea-level in the east, to 3050 m in the Andes, where it is sometimes found in the dense understorey of humid montane forest.

[*Thamnophilus ruficapillus* *ruficapillus*, Misiones, Argentina. Photo: José & Adriana Caloj]

species did not have the equivalent of the rising and falling series in their vocal repertoires.

In the "stipple-throated assemblage" of *Myrmotherula* antwrens (see Systematics), a second, distinct song is used in ritualized confrontations in which individuals face each other about 30 cm apart, lower the head, fluff out the back plumage, and pivot from side to side, vocalizing incessantly. All eight member species of the assemblage are thought to employ these displays, a fact which supports their monophyly.

Additional examples of species with two or more stereotyped vocalizations that fit the definition of songs include the Black-crested Antwren and some other *Sakesphorus* species, the Black-hooded (*Thamnophilus bridgesi*), Black and Cocha Antwrens in the genus *Thamnophilus*, the Plain Antwren and other *Dysithamnus* species, the White-fringed and Rusty-backed Antwrens, the Streak-capped Antwren and the Warbling Antbird. In the cases of the *Thamnophilus* antshrikes, the second vocalization consists of the repetition of a single note in variable-length series and, as such, resembles the "Softsong" of congeneric species.

The softsong, sometimes called the "faintsong" or "subsong", is another distinct type of song, given by paired individuals in close proximity. Softsongs, because of their low amplitudes, are recorded by human observers less often than are loudsongs. Those of some species consist simply of a monotonous repetition of the same note or combination of notes, but in other species they take the form of a more complex pattern of notes. The functions of softsongs are unknown; they could serve to maintain pair-bonds, but it appears that their functions are more complex. For example, Willis found that the Bicoloured Antbird, during the process of "nest-showing" (see Breeding), delivers a form of the softsong that rises and falls in both pitch and acceleration; he termed it "serpentine song".

It is difficult to communicate effectively in words a description of an antbird loudsong. These songs are better portrayed by using the same vocal measures as those employed in systematic studies. Thus, it is more useful to describe whether the rate of delivery, or the pace, accelerates or decelerates, how the frequency of the notes, or the pitch, changes to human ears, and how the

loudness, or intensity, shifts. Series of loudsong notes are often described as "countable" or "uncountable"; these terms provide a rough guide to the overall rate of delivery, as expressed by the ease with which the human ear can count the number of notes. Rapidly delivered songs, with the notes impossible to count, are often referred to as rattles, rolls and trills. A rattle can be defined as a rapid succession of low-pitched, harsh, grating notes; a roll is also low-pitched, but less harsh; and a trill is a higher-pitched piping series, generally more pleasing to the ear than is a rattle or a roll. Although it is considered helpful to give the number of notes, and the length in seconds, of one example of a species' loudsong, it is important to realize that statistical measures of an adequate sample of vocalizations have not been computed for most thamnophilid species. Examples should, therefore, be treated with a degree of caution.

Vocalizations other than songs are generally lumped into the catch-all category of "calls". Antbird species have multiple calls in their repertoires, but these are typically difficult to define precisely because the same basic type of note may be varied. For example, a downslurred note can be given clearly, as a whistle, or it can be frequency-modulated, with overtones that make it sound harsh. The number and complexity of thamnophilid calls are such that they are generally beyond the scope of simple verbal description, and only the most common are usefully transcribable. The variety of calls of ant-following species has, however, been described in detail in a number of papers by Willis.

Calls are frequently distinctive, and potentially useful in phylogenetic studies. For example, a call consisting of a "bark" followed by a rattling roll is given by the Collared Antwren and the Western Slaty Antwren, in the respective genera *Sakesphorus* and *Thamnophilus*, and it remains to be determined whether the vocal similarity of these distinctive rattles is a result of a common ancestry or of convergence. Single-noted calls can be equally informative. The crow-like "caw" of antshrikes in the genera *Thamnophilus* and *Sakesphorus* is learned quickly by novice fieldworkers, and its occurrence in antshrike repertoires may prove to be useful in establishing relationships of species in the two genera. The calls of some closely related species, such as the

Whereas some races of the **Blackish-grey Antshrike** are restricted to seasonally flooded evergreen várzea and igapó forest along rivers, others variously occupy mangroves, dense second growth around clearings, or savanna woodland. Some of these habitat shifts might reflect underlying genetic differences between populations. The race *cinereoniger* is particularly plastic in its habitat preferences, occupying flooded forest on river islands and along river margins, as well as stunted, dense savanna woodland growing on white-sand soils.

[*Thamnophilus nigrocinereus cinereoniger*, Anavilhanas Archipelago, Rio Negro, Amazonas, Brazil.  
Photo: Arthur Grosset]

Plain-winged and Mouse-coloured Antshrikes, are more easily distinguished than are their loudsongs.

Obligate ant-following species, when foraging over army-ant swarms, often deliver a distinctive "chirr", a harsh, vibrant note of about 0.25-0.5 seconds' duration that drops slightly in pitch and intensity. The chirrs of other species, often heard when an observer turns a corner on a trail and comes across an antbird, are described by some as an "annoyance" call, but they may just as easily be warnings of possible danger (see General Habits).

The functions of calls seem to overlap at least some of the apparent functions of loudsongs. They may, for example, serve to maintain contact between pair-members. With the exception of Willis's studies of ant-following species, however, there has been virtually no investigation of thamnophilid calls, even though they appear to offer important insights into the behaviour, as well as indicators of the phylogeny, of the members of this family.

Assertions that antbird vocalizations can be used in defining species limits, and possibly in higher-level taxonomic studies as well (see also Systematics), are based on the assumption that the vocalizations are innate and, therefore, reflect genetic differences among populations. The foundation for this assumption lies largely in studies of another suboscine family, the Tyrannidae, conducted by D. E. Kroodsma and his associates. The proposition that the same applies also to the Thamnophilidae is supported by an absence of evidence of vocal learning typical of oscine songbirds. For example, no dialectal differences in loudsongs can be found over vast portions of the geographical ranges of widespread antbirds, such as the Barred Antshrike. That is not to say, however, that antbird vocalizations are without intraspecific variation. In a study of the Spotted Antbird at a 100-ha site in Panama, S. C. Bard and associates found a degree of vocal variation which allowed individuals to be recognized by voice alone, and the same result was obtained by Morton and colleagues in an as yet unpublished study of the Dusky Antbird. Furthermore, song pace, an important vocal characteristic, appears to vary geographically, possibly in a clinal fashion in the case of some species, such as the White-flanked Antwren and the Black-faced Antbird, although it is not known whether such variation is congruent with genetic differentiation

at the same geographical scale, a subject currently under study. When using vocal characters in systematic studies of antbirds, the possibilities of individual and geographical variation demand adequate sample sizes and geographical coverage.

### Food and Feeding

All antbirds feed primarily on a wide variety of insects and other arthropods, including spiders, scorpions, centipedes and isopods. Orthopterans, including katydids, crickets and grasshoppers, along with cockroaches (Blattodea), mantids (Mantidae) and stick-insects (Phasmida), seem to be preferred prey items for many species, as do lepidopteran larvae, beetles and spiders.

In a study of the dietary consequences of substrate specialization for six species of Amazonian antwren, K. V. Rosenberg found that the diet composition of all six was qualitatively similar, with orthopterans representing the most important prey type. This study included two antwrens which forage on live leaves, three dead-leaf specialists, and one species, the Plain-throated Antwren, which is a substrate generalist. The three dead-leaf specialists, the Ornate, Stipple-throated and White-eyed Antwrens, took prey, other than the preferred orthopterans, roughly in proportion to their availability in dead leaves. In contrast, the diets of the White-flanked and Long-winged Antwrens, the two live-leaf foragers, bore little relation to the prey availability on live leaves; these species selected orthopterans, beetles and larvae more than would be expected on the basis solely of prey availability.

Rosenberg also conducted prey-selectivity experiments on captive antwrens placed in outdoor enclosures. Individuals of each foraging group exhibited similar degrees of selectivity from twelve prey categories offered to each species. All individuals readily captured and consumed cockroaches, spiders, crickets and small katydids, as well as dragonflies (Odonata) and butterflies. Larger katydids were usually captured immediately, but required substantial handling time before being killed and consumed. Hard-bodied or brightly coloured grasshoppers either were eaten after initial hesitation or were rejected. Conversely, nearly all ants,

The eight species currently constituting the genus *Dysithamnus* are all birds of humid forest. Some live in the lowlands while others, including the **Rufous-backed Antwren**, are restricted to higher altitudes. This species, possibly the most attractive member of the group, lives in montane evergreen forest and old second growth between 750 and 1700 m in the mountains of south-east Brazil. It is easily found in a few Brazilian national parks, including Serra dos Órgãos and Itatiaia, where these forests are well protected.

[*Dysithamnus xanthopterus*, Pico dos Marins, São Paulo, Brazil. Photo: Edson Endrigo]

flies and wasps and most beetles and heteropteran bugs were ignored or rejected. Harvestmen (Opiliones) were also ignored by all three species of antwren to which they were offered.

Field observations suggest that many thamnophilids are even more specialized in their prey preferences than the preceding examples would suggest. For example, the Manu Antbird, a bamboo specialist, has been observed to take mostly small lepidopteran larvae, while many terrestrial-foraging species and army-ant followers consume particularly large numbers of crickets, cockroaches, sowbugs (Isopoda) and spiders, and the Silvered, Band-tailed and Black-chinned Antbirds all take large numbers of aquatic insects. In each of these cases, however, it is not known if the birds are demonstrating a specialized preference or are merely taking prey in proportion to their abundance in a given habitat.

Many antbirds, even small antwrens, seem capable of eating relatively large arthropods. Larger prey items represent greater caloric rewards but often come at the cost of increased handling time, particularly for the smaller members of the family. Many antbird species will repeatedly bash larger arthropods against branches before using the bill to remove the prey's wings, legs or urticating spines in methodical fashion. The wings of moths, butterflies, dragonflies and larger orthopterans are routinely clipped, and, in some cases, veritable dissections are made of the other appendages and body segments. Many species habitually wipe the bill on a branch following prey consumption. At times, antbirds may show initial interest in large prey items that ultimately prove too big or too dangerous to handle. In the prey-selectivity experiments, Rosenberg found that captive White-flanked Antwrens ate only two of six katydids that were greater than 30 mm in length, and that Long-winged Antwrens did not attack any of four katydids larger than 25 mm. In those instances when they did not eat the katydids, the birds usually showed great initial interest in the food but either were hesitant to attack or seemed physically incapable of grabbing and subduing the prey. A. F. Skutch reported a case of a female Dusky Antbird being deterred from attacking a spider that was too large. When the antbird found the spider, which measured about 5 cm across its spread legs, clinging to the underside of a leaf, it cautiously stretched its neck forwards in an attempt to seize the

arachnid with its bill; in response, the spider reared back and waved its front legs in an aggressive display, which was enough to make the bird withdraw and give up.

Several thamnophilid species have been found regularly to eat snails and slugs. This is especially true of a number of the large Atlantic Forest antshrikes, including the Giant, Spot-backed, Tufted and Large-tailed Antshrikes. Great Antshrikes and Wing-banded Antbirds are among the more widespread species that also regularly eat gastropods.

Many more antbirds are known to take small vertebrates, at least occasionally. Such prey consist mainly of small lizards, mostly *Anolis* species though also geckos, but they also include frogs and snakes. As would be expected, this behaviour is especially common among many of the antshrikes, the larger and more hooked bill of which is well equipped for handling vertebrate prey. A male Giant Antshrike in Rio Grande do Sul, in south-east Brazil, was observed to dislodge a large tree-frog (*Hyla*) from a perch several metres above the ground. The frog, which had an estimated body length of 8 cm, and legs much longer than that, jumped to the ground, whereupon the antshrike immediately dropped half the distance to the ground, scanned for a second and then pounced on the frog, skewering it with its massive bill; it then bashed the frog several times on the ground, before swallowing it. The speed and efficiency with which the antshrike dispatched such a relatively large and mobile prey item was impressive, indeed. Small frogs and lizards are also captured on occasion by smaller antbirds. The Black-headed Antbird has been found to take lizards up to 7 cm in length, as well as small snakes. Immaculate, Chestnut-backed, Bicoloured, Spotted and Scale-backed Antbirds are among the other non-antshrikes known to take reptiles and amphibians. In Rosenberg's prey-selectivity experiments discussed previously, captive White-flanked and Plain-throated Antwrens captured and consumed lizards 5 cm long, whereas Ornate Antwrens would not eat small lizards. It is not known whether such small thamnophilids would take vertebrate prey under natural conditions.

Small snakes are probably taken regularly only by the larger species of antshrike, such as the Giant, Large-tailed and Tufted. The Giant Antshrike is also known to have taken small rodents, and all three of those species have been reported to steal eggs and

nestlings from nests. Collared Antshrikes are regularly mobbed by small birds such as hummingbirds (Trochilidae), grassquits (*Tiaris*) and seedeaters (*Sporophila*), which suggests that they, too, may at least occasionally prey on nests. Great Antshrikes have also been recorded as preying on small rodents. In the Pantanal region of Brazil, Great Antshrikes regularly forage in drying marshes, where they use the leaves of water hyacinths as platforms for extracting tadpoles and minnows from the water.

Some antbirds include fruit or other vegetable matter in the diet. The Variable Antshrike, the Spot-breasted Antwren (*Dysithamnus stictothorax*), the Rufous-backed Antwren (*Dysithamnus xanthopterus*) and the Rufous-winged Antwren have all been found to consume berries of mistletoe (Myrsinaceae: *Rapanea*). A pair of Variable Antshrikes in south-east Brazil was observed feeding on *Melastoma* fruits, which they severed at the base and swallowed, after which the birds regurgitated a papery skin or husk. Barred and Black-crested Antshrikes have been observed to eat the fruit of capsicum (*Capsicum*), as has the Russet Antshrike, and small fruits have been found among stomach contents of Fasciated Antshrikes, Guianan Streaked Antwrens and Black-headed Antbirds. The stomach contents of one Bar-crested Antshrike contained seeds of pomegranate (*Punica granatum*), and various unidentified seeds have been found in the stomachs of Barred, White-bearded and Great Antshrikes and of Chestnut-backed and Wing-banded Antbirds.

Thamnophilids employ a wide range of foraging techniques to secure their predominantly arthropod prey. The majority of species are arboreal, and, although antbirds are most common in the understorey, many occupy the middle storey. A few, particularly *Terenura* and *Herpsilochmus* antwrens, the Russet, Spot-winged and Fasciated Antshrikes, and the Pygmy, Moustached, Yellow-throated (*Myrmotherula ambigua*) and Sclater's Antwrens (*Myrmotherula sclateri*), can be found in the canopy, 25 m or more above ground.

Most species perch-glean arthropods from live leaves, stems, vines or branches. Some will glean prey primarily from the tops of leaves and others mainly from the undersides of overhanging leaves, and still others will utilize all surfaces. Most antshrikes are somewhat generalized gleaners, moving through foliage with heavy hops, and pausing for anything from several seconds to up to a minute or more between hops, during which time they actively scan for prey. Food items, once spotted, are usually seized by reaching or by short lunges. Some antshrikes, such as the Plain-

winged Antshrike, and many smaller thamnophilids, particularly the antwrens, glean prey mostly in short, fluttering or hovering sallies to vegetation. Several terrestrial species, such as the White-bibbed Antbird and the Squamate Antbird, employ a variation in which they walk along the forest floor, periodically jumping upwards to take prey from the undersides of overhanging leaves. Many of the antwrens are particularly acrobatic, often hanging head downwards from the tips or margins of leaves or from leaf petioles, or clinging to the undersides of large leaves, in their attempts to scan vegetation and secure prey. In general, the smaller species, such as the antwrens and antvireos, tend to be more active and faster-paced in their foraging, spending less time pausing and scanning between movements than do the larger species. Many of the more active species habitually flick their wings in a shallow arc as they forage, possibly to startle cryptic prey into moving and, thereby, revealing their presence. Once dislodged, certain prey, particularly orthopterans such as katydids and grasshoppers, will jump or fly rapidly downwards for several metres in an attempt to evade capture. In response, many antbirds engage in equally abrupt, fluttering pursuits, often through several layers of vegetation.

A few members of the family obtain insects primarily by making longer-distance sallies to vegetation or into the air. The Speckled, Pearly, Dusky-throated and Saturnine Antshrikes all attack prey chiefly in quick, darting sallies to vegetation, although they sometimes make short looping sallies to take prey from the air. The Cinereous and Bluish-slate Antshrikes are extreme examples of aerial hawkers within the family. Like many tyrant-flycatchers, they perch upright, constantly scanning, and then sally for distances of 1-5 m, or occasionally up to 10 m, to snatch prey from the air or from vegetation. These more specialized long-distance salliers are core members of mixed-species flocks, and often feed opportunistically on insects flushed by other, more actively moving flock-members. Band-tailed and Black-chinned Antbirds, which normally feed along streambanks and margins of flooded forest, have been observed to make repeated steep diagonal sallies from branches or vines to seize aquatic insects from the water's surface, much in the manner of tiny kingfishers (Alcedinidae).

Many understorey antbirds are adapted for clinging laterally, with the top leg flexed and the bottom leg extended, to thin vertical saplings and similar perches that often predominate in the shaded forest interior. From such vantage points, usually within

Several species of antbird are adapted to life on the constantly shifting river islands in lowland Amazonia. They are so particular in their choice of habitat that they are rarely found on adjacent mainland. Although the **Leaden Antwren** often joins the select community of antbirds on river islands, it cannot strictly be called a "river-island specialist", as it also occurs in the seasonally or permanently flooded forests bordering white-water rivers (várzea forest) and black-water rivers (igapó forest). When it occurs on islands, it tends to occupy mature forest, while other species specialize on younger regrowth.

a metre of the ground, they may scan surrounding foliage as well as the floor, and often pounce on prey from above before hopping back up to another perch. The Band-tailed and Black-chinned Antbirds, in addition to employing the sallies described above, more often cling to overhanging vines or branches just above the surface of small streams, from where they reach downwards to pick prey from the water's surface or from the algal scum that clings to partially submerged branches, logs and plant stems at the waterline.

A few, largely terrestrial antbirds forage mainly for arthropods concealed in the leaf litter. They methodically turn over or toss leaves, either by grasping the leaf in the bill or by inserting the bill beneath the leaf and brushing it aside with a rapid sweeping motion. In many instances, the leaves being thrown are larger than the bird itself. This foraging technique is identical to that used by leaf-tossers (*Sclerurus*), members of the Furnariidae. The Wing-banded Antbird is probably the most habitual leaf-tossing thamnophilid, using its bill as a tool to push the leaves, rather than grasping and throwing them. Individuals have been observed to spend more than 30 minutes continuously tossing leaves within an area no more than a few metres in diameter. This specialized foraging behaviour is reflected in that species' diet, which is known to encompass a variety of leaf-litter organisms, including crickets, cockroaches, sowbugs, gastropods and even millipedes (Diplopoda), the last a seemingly noxious prey type that is usually avoided by most antbirds. The Scalloped Antbird of eastern Brazil and the Caura Antbird, a Guianan Shield endemic, also employ leaf-tossing as a major part of their foraging repertoires, although neither species is so dependent on this technique as is the Wing-banded Antbird. Most of the ant-following species and antshrikes that follow escaping prey to the ground will toss leaves in direct response to the sight of an arthropod moving beneath a leaf to hide, but this appears to be an opportunistic response rather than a regular search behaviour. Other antbirds obtain a substantial proportion of their food from leaf litter without tossing leaves. They either probe beneath litter with the bill, or seize items from the surface, often by pouncing from above-ground perches.

In addition to leaf-tossing, the Caura Antbird has evolved a foraging method that is seemingly unique among the Thamnophilidae. In the only known study of the species, K. J. Zimmer found that Caura Antbirds made liberal use of the boulders that

seem to be an integral part of their habitat (see Habitat). Much of their foraging time was spent in creeping over large boulders, often clinging laterally to nearly vertical rock faces, and exploring large crevices and inspecting narrow fissures in the manner of Rock Wrens (*Salpinctes obsoletus*) and Canyon Wrens (*Catherpes mexicanus*) of North America. While creeping about on rocks, the antbirds frequently probed in mosses and small ferns covering the surface, but they spent most of their time inspecting the leaf litter trapped between the roots and vine tangles of trees overtopping the rocks. They routinely squeezed themselves into small spaces between the rock surfaces and overlying roots and vines, remaining in these somewhat "canopied" niches to forage for up to a minute or more at a time. When seeking food on rocks, the antbirds tended to spend most of the time in somewhat protected locations, within the interior of vine tangles and root-masses overtopping the rocks, within crevices in the rocks, or beneath rocky ledges and overhangs. Caura Antbirds spent more than 80% of their foraging time on rocks and overtopping vegetation or on the ground directly beneath overhanging rocks. Zimmer's study was conducted in February, during the dry season. The importance of rocks as foraging sites may be increased in dry periods, when favourable moisture-retaining micro-climates are created along rock edges or crevices. Furthermore, the tendency for overtopping root-masses and vine tangles to trap leaf litter is accentuated during the dry season, when many trees drop their leaves. Such accumulations of organic litter may provide attractive sites for arthropods when the forest is water-stressed. It is interesting that no other bird species was observed to exploit the extra resource dimensions created by the large rocks at the Venezuelan study site.

As might be expected from their peculiar bill shapes, the three bushbirds in the genera *Neotantes* and *Clytoctantes* appear to have evolved some highly specialized foraging techniques that may set them apart from other antbirds. Detailed information is available only for the Black Bushbird, but all three species seem to be birds of vine tangles, treefalls and dense thickets, and the few foraging observations for the other two bushbirds appear to be consistent with those for *Neotantes*. The Black Bushbird occasionally probes in suspended, curled dead leaves, or picks at vine and branch surfaces, but much of its foraging involves sub-surface manoeuvres. It uses its bill to hammer repeatedly at a

A large proportion of antbirds are restricted to the shady understorey of humid forest. Many of these forest-floor species so rarely cross openings, and so avidly avoid even small patches of sunlight, that they are suspected to be photophobic. One such species is the **Dull-mantled Antbird**; it lives in the understorey of wet evergreen forest, primarily in damp ravines and on slopes bordering streams, especially where treefalls have resulted in a dense, herbaceous understorey.

[*Myrmeciza laemosticta laemosticta*, Braulio Carrillo National Park, Costa Rica. Photo: Kevin Zimmer]

Many antbird species, long known from specimens but almost unknown in life until recent years, have proven to be nearly restricted to habitats growing on white-sand soils. Within these sandy soil formations, many antbird species occupy a variety of micro-habitats.

**Cherrie's Antwren**, for example, occurs in stunted, poorly drained woodland on white-sand soils, as well as in dense copses and palm-filled borders of seasonally flooded gallery forest in savanna regions. In more humid regions, it ranges from shrubby thickets and borders of streams into adjacent taller várzea forest at ecotones.

branch, woody vine, palm rachis or rotten log until a hole is opened. It then uses its chisel-shaped bill as a wedge to pry loose strips of live bark or stem fibres, or to flake off dead bark, after which it picks repeatedly at small subsurface prey, which are swallowed without special manipulation. Individuals have been seen to feed in this manner at a single station uninterruptedly for ten minutes or more. The Recurve-billed Bushbird (*Clytoctantes alixii*) and the Rondonia Bushbird (*Clytoctantes atrogularis*), each of which has an even larger, more wedge-shaped bill than that of the Black Bushbird, have also been seen hammering at woody vines or stripping plant fibres from heavy stalks.

Antbirds have proven to be opportunistic foragers, as well. A pair of Planalto Slaty Antshrikes in Mato Grosso, Brazil, was observed while foraging in the understorey of an area of humid forest that had just been burnt. The antshrikes clung to charred saplings at less than 1 m above the ground, and pounced on subsurface arthropods that emerged from the still smouldering topsoil. On Barro Colorado Island, Panama, Western Slaty Antshrikes have been reported as regularly gleaning items from the insect screens of buildings, the insects apparently remaining after having been attracted by artificial lighting at night. More remarkably, Barred Antshrikes have been known to attend feeding stations in Venezuela, and to visit houses on the island of Tobago in order to take soaked bread. A most unusual event was reported by Skutch, concerning a Bicoloured Antbird that repeatedly followed him on walks through the forest, using him as a "beater" to flush insects. Over a 16-month period, the bird would tag along at the ornithologist's feet, waiting patiently as he used a stick to stir up arthropods and small frogs from the leaf litter; the antbird then pounced on and consumed the food. So tame was this individual that Skutch was able to stroke it lightly with his stick without causing the bird to fly. Skutch had similar experiences with a few other Bicoloured Antbirds that foraged opportunistically at his side, but none so prolonged and predictable as with the first bird, which he had named "Jimmy", a contracted version of *Gymnophis*.

One of the most conspicuous avian phenomena of tropical forests is the mixed-species foraging flock. These flocks form shortly after dawn and persist until late afternoon, day after day,

throughout the year. Antbirds are key components of understorey mixed-species flocks of insectivores and, to a much lesser extent, of similar flocks that roam the forest canopy. These flocks, regardless of geography, share certain common properties. First and foremost, each flock contains a core of species the territories of which coincide exactly. This common territory thus defines the territory of the flock. Membership of the flock is typically limited to a single pair, or a single family of adults with fledged young, per species. Territorial defence is communal, with boundary disputes arising only when neighbouring flocks meet; aggression is then directed only towards conspecifics, but, because the territories of core flock-members coincide, this means that several pairs of birds of different species are likely to be defending their territories at the same place and time. Core flock-members also nest within the jointly held flock territory, and fledged young join their parents in foraging with the flock. Among core species, flock membership is constant, with the same individuals foraging together day after day. Flocks typically contain a variable number of non-core species, the membership of which is not constant.

The exact mechanisms that maintain the cohesion of different species within stable flocks are not perfectly understood. It is thought that flock cohesion relies heavily on so-called "nuclear species" that attract other "attendant species". These nuclear species are thought to promote both the formation and the maintenance of mixed-species flocks through the conspicuous nature of their calls, coloration or behaviour. It has been demonstrated that flocks which lack such conspicuous species are less stable and more likely to dissolve than are those in which these species are present.

Much of what is known of mixed-species flocks is based on field studies by C. A. Munn and J. W. Terborgh, who worked at Cocha Cashu Biological Station, in Manu National Park, Peru, although their work was both preceded by and followed by studies by other ornithologists working at locations in Central America, Amazonia, the Guianas and south-east Brazil. Munn and Terborgh found that two *Thamnomanes* species, the Bluish-slate and the Dusky-throated Antshrikes, served as nuclear species in the understorey mixed flocks of insectivores at their study

sites. Both antshrikes are active and noisy, giving loud, distinctive calls repeatedly throughout the day. These calls seem to provide a rallying cry for the other flock-members as the flock assembles each morning, and serve to signal the movements of the flock throughout the day. They are very different from the two antshrikes' loudsongs, which are given primarily at territorial boundaries when two or more flocks come into contact. Munn and Terborgh found that the calls of the antshrikes often directed the flock's movements: frequently, an antshrike would move to and call from a spot 20-30 m away from the flock, with the almost invariable result that other flock-members would follow. At Cocha Cashu, the Bluish-slate Antshrike seemed to be the more important of the two, by virtue of its louder, more insistent calls and higher foraging position. Where Bluish-slate Antshrikes were absent, however, those authors noted that flocks with virtually the same composition still formed around pairs of Dusky-throated Antshrikes.

It is now recognized that, throughout most of the Amazonian and Guianan lowlands, one or two species of *Thamnomanes* antshrike are the leaders of most understorey flocks of insectivores. In south-east Peru and adjacent northern Bolivia and western Brazil, the Bluish-slate Antshrike and the Dusky-throated Antshrike play this role, as described for Cocha Cashu. Elsewhere, the Cinereous Antshrike replaces the Bluish-slate as the primary flock-leader, with either the Dusky-throated or its counterpart, the Saturnine Antshrike, taking the less conspicuous and seemingly less important secondary role. Both of the last two species forage lower in the understorey, and give calls that are less far-carrying and less insistent than the noisy "machine-gun" chatters of the more conspicuous Cinereous and Bluish-slate Antshrikes. It has been noted that, where two species of *Thamnomanes* occur in the same flock, they tend to forage at different, although slightly overlapping, heights. Where Cinereous Antshrikes occur in the absence of either Dusky-throated or Saturnine Antshrikes, they often forage at lower levels than they do when one of the other two is present.

The members of a mixed-species flock come together shortly after dawn, seemingly drawn to the location calls of the *Thamnomanes* antshrikes. Soon thereafter, they begin foraging. The main understorey flock studied by Munn and Terborgh moved at an average rate of 60 m per hour, although the pace of any given flock can vary considerably. Foraging continues through-

out the day, although frequently with something of a lull in the middle of the afternoon; by late afternoon, activity slows markedly. On the basis of morning assembly patterns, Munn and Terborgh considered that flock-members at Cocha Cashu roosted separately. Only once were they able to follow individuals to roosting places, when a pair of Dusky-throated Antshrikes roosted within 70 m of the spot where the flock assembled on the following morning. They found that flocks fragmented gradually in the late afternoon, as species left, one by one, for their respective roosts. By contrast, J. Gradwohl and R. Greenberg, working with mixed-species flocks in Panama, where *Thamnomanes* antshrikes are absent, discovered pairs of their two nuclear species, the Dot-winged Antwren and the Checker-throated Antwren, roosting in the same tree on all eight occasions on which roosts were observed. Moreover, they found that many of the attendant species, including the Western Slaty Antshrike and the White-flanked Antwren, also roosted in the same tree or within 15 m of the two nuclear species. In one flock, the Western Slaty Antshrike usually slept on the same branch as the Checker-throated Antwrens.

As previously stated, territorial conflicts arise when two flocks encounter each other. The nuclear species are usually the first to engage in confrontation with their counterparts in the other flock, this time giving loudsongs, rather than the calls that normally direct flock movements. Other flock-members become involved, but only to the extent that they are engaged by their "mirrors" in the neighbouring flock. Territorial vocalizations are often accompanied by posturing and physical displays, as conspecifics of several species face each other. Species not represented in the neighbouring flock continue foraging, waiting for the action to cool down and for the flock to move on.

Aggression within flocks is rare, probably mainly as a result of lack of intraspecific competition. Although core species of understorey flocks are all insectivores, competition is muted in a number of ways. Typically, member species vary considerably in size, from the largest woodcreepers (Dendrocolaptidae) to the smallest antwrens and tyrant-flycatchers, and this variation is possibly accompanied by a corresponding variation in the preferred types and sizes of prey. Within a group of similarly sized relatives, such as *Myrmotherula* antwrens, differences in foraging height, foraging technique and substrate use may allow a partitioning of resources that reduces competition, although D. F. Stotz, in a study of antwren foraging behaviour at three Amazonian sites and one in the Atlantic Forest, found such differences to be fewer than expected. A full understanding of how so many similar species co-exist is still to come. In the Peruvian study of Munn and Terborgh, the seven *Myrmotherula* species differed as follows. Plain-throated Antwrens foraged much lower than all other antwrens, at a mean height of 0.3 m above ground, whereas Pygmy Antwrens foraged mostly in vine tangles and much higher than all others, at a mean height of 12.5 m. White-eyed Antwrens exploited exclusively dead leaves at lower levels, on average 2.8 m, while Ihering's Antwrens specialized on dead leaves and on the undersides of vines and dead twigs at somewhat higher levels, averaging 5.1 m. Grey Antwrens foraged on live leaves and stems in the mid-storey, at a mean height of 8.8 m. Finally, the Long-winged and White-flanked Antwrens worked live leaves in the understorey at roughly the same level, around 5 m above the ground. At first glance, the last two species would seem to be nearly identical in their foraging behaviour and more likely, therefore, to compete with one another. The Long-winged Antwren, however, tends to work more open branches of understorey trees, particularly in their outer portions, and tends to forage more by short sallies or hover-gleans to the undersides of leaves, whereas the White-flanked Antwren is more of a perch-gleaner and forages more in the interior portions of trees, where the foliage is denser.

Paired birds maintain their membership of flocks when breeding. The male and the female trade off incubation and brooding duties, with the free member of the pair joining the flock. When young are being fed, the adults may stick closer to the nest, joining the flock only as it passes in near proximity. Once the young have fledged, and are sufficiently grown to fly well, the entire family accompanies the flock, the bond between parents and offspring sometimes lasting for several months (see Breeding).

Several antbirds have a strong association with bamboo. The **Ferruginous Antbird**, for example, is common with all but one of its congeners, is usually restricted to this micro-habitat. It occurs in the understorey, mid-storey and canopy of bamboo thickets, in evergreen forest in the hills of south-east Brazil, which means that it is usually found at forest edges, or at regenerating light-gaps, such as treefalls, landslides and man-made clearings.

[*Drymophila ferruginea*, Serra da Cantareira, São Paulo, Brazil. Photo: Edson Endrigo]

The **Mato Grosso Antbird** is a common bird in the Pantanal region of Brazil. Here, it is usually found near water, inhabiting the understorey of thickets, gallery forests and copses of seasonally flooded savanna woodland with an abundance of vines. Further to the west, in Bolivia, it occurs in moist Chaco woodland with numerous large columnar cacti, and an abundant cover of terrestrial bromeliads.

Munn and Terborgh recognized several categories of flock participation that help in understanding the variation between roles of species within flocks. They termed these six categories "Type I" to "Type VI". Type I species, or "core" species, typically occurred in all understorey flocks, and held territories that coincided with those of other core members. Type II species were simply core species with lower population densities than Type I, such that they did not occur in all flocks but were, nevertheless, obligate flock species. Type III species had population densities much greater than those of the core species, with correspondingly smaller territories, smaller than the flock territory; they foraged on their own for much of the time, but joined flocks whenever these passed through their territories, and followed a flock for as long as it remained in its territory. The Plain-throated Antwren and the Black-faced Antbird were examples of Type III at Cocha Cashu. Type IV species were those that opportunistically switched between faster-moving canopy flocks and slower-moving understorey flocks. No antbirds at Cocha Cashu were ranked as Type IV species, although, in many places, this designation could be applied to Spot-winged Antshrikes. Type V species used the forest in a patchy fashion, being restricted to a particular microhabitat such as vine tangles, bamboo thickets or treefall gaps; these birds follow passing flocks regularly, but only so long as the flock remains in the preferred habitat. Type V species at Cocha Cashu included the Fasciated, White-shouldered, Plain-winged and Spot-winged Antshrikes, the Grey Antbird and the Dot-winged Antwren, all of which were more or less confined to areas with extensive vine tangles, and the Ornate Antwren, which was restricted to bamboo. Type VI species were labelled "occasional flock-joiners", those that foraged mostly by themselves, but occasionally joined flocks for short periods of time. No antbirds at Cocha Cashu were categorized as Type VI species.

One of the primary questions surrounding the phenomenon of mixed-species flocks is that of the benefits derived from membership. One possibility is that flocking may enhance the foraging efficiency of some or all members of the flock. This could happen if some members benefited by capturing insects flushed by others, or if greater numbers of flock participants increased the likelihood of locating food sources that could be exploited by all members of the group, as with fruiting trees or emergent swarms of insects. Flocking may also reduce both intraspecific competition, through enhanced spacing of territories, and

interspecific competition, through regulation of return times, thereby preventing overdepletion of resources in any given patch. Potential costs of flocking include increased competition for food. In this context, however, the example of flock-associating antwrens at Cocha Cashu, although not strongly supported by Stotz's study at four other sites, indicated that related species might reduce competition in mixed-species flocks by foraging at different heights, on different substrates or prey, or by utilizing different foraging techniques.

It seems probable that there is no single benefit driving flock participation, and just as likely that the benefits and costs derived from flock membership are not shared equally among all species. One of the likeliest benefits is that of lowered risk of predation by bird-eating hawks (Accipitridae). Although foraging flocks are probably more conspicuous to predators than are single birds or pairs foraging alone, this is probably more than compensated for by the increased vigilance provided by numerous pairs of birds foraging at multiple levels in the understorey. An added benefit is derived by flocks in which one or more nuclear species performs the role of sentinel. The four *Thamnomanes* antshrikes are among the few flock-members that give loud and unambiguous alarm calls, to which other flock species have been shown to respond. All four, but especially the Bluish-slate and Cinereous Antshrikes, are aerial hawkers or sally-strikers that sit still and upright while scanning for prey. They are in a much better position to spot potential predators than are the foliage-gleaning and bark-foraging members of the flock, most of which are in near-constant motion and often have the head buried in vegetation. The antshrikes, too, benefit from this relationship, because other, more active species in the flock serve as "beaters", flushing prey that the antshrikes, with darting speed, are able to exploit. The antshrikes end up by expending less energy, with greater returns, than they would if they foraged alone. The other flock-members are more free to concentrate on foraging, which means that their efforts are likely to yield higher numbers of prey per unit time than would be the case if they had to devote considerable time to scanning for predators.

This mutually beneficial relationship is analogous to that found between the various species of shrike-tanager (*Lanio*) and the species with which they travel in mixed canopy flocks. Shrike-tanagers, like *Thamnomanes* antshrikes, perch upright and sally to take prey from the air or from vegetation. They, too,

When it was first discovered in the mid-1990s, the **Marsh Antwren** was thought to belong with *Cercomacra*. Due to irregularities in morphology and ecology, however, a new genus was erected, *Stymphalornis*. Recent research suggests that this genus should be subsumed within *Formicivora*, but the preferred habitat of the Marsh Antwren remains unique in the family. It is restricted to a small area of Paraná and Santa Catarina, Brazil, where it frequents coastal marshes and wetlands dominated by the rushes *Typha domingensis* and *Scirpus californicus*.

give loud alarm calls that are recognized by all members of the flock. The White-winged Shrike-tanager (*Lanio versicolor*) regularly gives false alarm calls; these have the effect of scattering the other flock-members, which, in diving for cover, often flush more insects for the shrike-tanager. The latter also emits legitimate alarm calls when predators are near, so that other flock species cannot distinguish between a false alarm and the real thing. The consequences of ignoring a real alarm call are potentially grave, which serves to maintain the benefits to the shrike-tanager. The *Thamnomanes* antshrikes have not yet been documented to "cry wolf" in the manner of the shrike-tanagers, but they may do so.

Mixed-species flocks in lowland Panama were shown by R. H. Wiley and by Gradwohl and Greenberg to function in much the same way as the Cocha Cashu flocks studied by Munn and Terborgh, but with different nuclear species. As mentioned above, there are no *Thamnomanes* antshrikes in Panama, where the nucleus of the understory flocks consisted of pairs or families of Checker-throated Antwrens and Dot-winged Antwrens that had completely overlapping territories. These species defended common boundaries in conspicuous territorial-border displays, often displaying in the same trees, but with their defences directed only at conspecifics in the neighbouring flocks. Gradwohl and Greenberg found that home ranges of most of the attendant species either were smaller than one antwren territory, or were larger and included three or more antwren territories. As the two species of antwren moved through the territory, other species joined and left them within the constraints of their own spacing systems. Those with larger home ranges, such as woodcreepers, appeared to cover the home range by switching from one antwren flock to another. Species with smaller territories, such as the Western Slaty Antshrike, stayed with the flock only for as long as it remained within the species' own territory, before dropping out.

Wiley considered the White-flanked Antwren to be a third nuclear species in understory flocks, although he found the three species of antwren co-occurring in only ten of 29 flocks, and detected only one of the three in another ten of 29 flocks. He observed that all three antwrens performed a mobbing function, thus probably enhancing predator detection for other flock-mem-

bers. The three species reduced potential competition among themselves in much the same way as did those at Cocha Cashu. Dot-winged Antwrens foraged primarily in the densest vine tangles, in areas of much greater foliage density than in those used by the other two. The Checker-throated and White-flanked Antwrens foraged in areas of similar foliage density, but the former fed exclusively on arthropods hidden in dead leaves, whereas the latter gleaned insects almost entirely from live vegetation. Wiley suggested that the White-flanked Antwren and the Checker-throated Antwren had co-operative roles that enhanced the maintenance of flock cohesion. The Checker-throated Antwren was the most vocal species in giving alarm calls and seemed, therefore, to act as the chief flock sentinel. Male White-flanked Antwrens, with a boldly contrasting black body and white flank patches, the latter made more conspicuous by constant wing-flicking, were thought to have a special role in maintaining flock cohesion by means of visual signals. By contrast, Gradwohl and Greenberg did not consider the White-flanked Antwren to be a nuclear species in their flocks. They found it to have territories of a size equivalent to between two and three Checker-throated/Dot-winged territories, thus making the White-flanked Antwren more like a Type II species as defined by Munn and Terborgh.

C. A. Botero evaluated the role of the White-flanked Antwren as a potential nuclear species in mixed flocks in gallery forest in eastern Colombia, and experimentally tested the hypothesis that the conspicuous flashing of the white flank patches of males promotes flock cohesion. The experiment involved applying alcohol-based black dye to the flanks and underwings of mist-netted male antwrens, and comparing the various parameters of flock cohesion and association before and after this treatment. Mixed-species flocks that included White-flanked Antwrens contained, on average, a significantly higher number of species than did those without the antwren. Botero found that the dyed male antwrens continued to wing-flick at rates similar to those before dyeing. Furthermore, the absence of white flank feathers did not seem to affect the performance of individuals during territorial encounters, its recognition by other conspecific members of the group, or the degree of association between conspecifics while foraging. In addition, wing-flicking rates were not correlated with the number of attendant species in the flocks, nor were there any

significant changes in the number of such species following the dyeing of the antwrens. Finally, manipulation of flank and underwing colours did not affect either the distances between the different attendant species and the nearest male antwren, or the average time that most of those species spent with the flock.

Male White-flanked Antwrens met many traditional criteria for nuclear species; for example, they formed intraspecific groups, they were present in most mixed-species flocks, they were visually conspicuous, and flocks with antwrens contained more species than did those without antwrens. Nevertheless, Botero concluded that they did not promote interspecific cohesion within the flocks at his study site. He suggested that the effort and concentration required for attendant species to follow the constantly moving visual signal of the antwrens' flank-flashes were incompatible with their foraging requirements. The limitations of visual signals in the dense understorey vegetation of tropical forest are indicated by the fact that paired males and females of most antbird species, including the White-flanked Antwren, rely on various types of vocalizations to maintain contact when separated by more than a few metres (see Voice).

This still left the question of why flocks with White-flanked Antwrens contained more species than did those without. Botero hypothesized that bigger flocks might have been more attractive to White-flanked Antwrens, or that the conspicuousness of male antwrens could increase the probability that other birds would detect and join the flock. In comparing the possible nuclear role of the White-flanked Antwren with that of *Thamnomanes* antshrikes, it is worth noting the findings of P. C. Stouffer and R. O. Bierregaard from the forest-fragmentation project near Manaus, in Brazil (see Status and Conservation). Fragmentation of the forest resulted in the disappearance of both Cinereous and Dusky-throated Antshrikes from forest isolates. The elimination of these nuclear species was followed by the "complete disintegration" of mixed-species understorey flocks, even when White-flanked Antwrens and some other regular attendant species maintained their population densities.

One of the factors frequently invoked as promoting increased species diversity in tropical forest is the availability of a variety of resources that are absent or of restricted availability in temperate forest. Among the more obvious examples are fruit, nectar and abundant insects, which are present throughout the year. A less obvious resource is dead leaves. In many tropical forests,

dead leaves falling from the canopy are trapped by vines, palm fronds and other vegetation, particularly in the understorey, where vegetation is often most dense. This creates an aerial or arboreal leaf litter, which, as the leaves wither and curl, provides hiding places for many primarily nocturnal arthropods. A number of tropical bird species forage for arthropods in the recesses of these curled, dead leaves, and a smaller subset has been shown to specialize on this substrate. Presumably, the pronounced seasonality of leaf fall at temperate latitudes limits the ability of both arthropods and birds to specialize on dead leaves in these respective ways.

Remsen and Parker were among the first to point out the contribution to Neotropical bird-species richness of the year-around availability of suspended dead leaves. Working in Peru and Bolivia, they grouped dead-leaf users into one of three categories: "specialists", those species seen to search dead leaves in more than 75% of all observations; "regular users", those searching dead leaves in 25-75% of observations; and "occasional users", species for which they recorded the behaviour in less than 25% of all observations. Using these criteria, they found eleven species at their study sites to be specialists in searching dead leaves. Two of those were antbirds: the White-eyed Antwren, for which 95.3% of all foraging manoeuvres were directed to dead leaves, and the Ornate Antwren, for which the corresponding figure was 98.9%. These findings agreed well with those of other researchers concerning some other *Myrmotherula* antwrens with a stippled throat pattern. Both Parker and Willis had pointed out similar behaviour for Rufous-tailed and Stipple-throated Antwrens, and a number of ornithologists had commented on or investigated the dead-leaf-searching behaviour of Checker-throated Antwrens, none more thoroughly than Gradwohl and Greenberg. More recently, K. V. Rosenberg conducted numerous studies of avian dead-leaf foragers in general, and, in particular, of dead-leaf specialists among the *Myrmotherula* antwrens, which he and Hackett termed the "stipple-throated antwren assemblage" (see Systematics).

According to Remsen and Parker's criteria, all members of the "stipple-throated antwren group" appear to be specialists, or obligate users of dead leaves. Gradwohl and Greenberg recorded that Checker-throated Antwrens in Panama spent 98% of their foraging time at dead leaves, and Rosenberg, at study sites in Peru and Bolivia, obtained nearly identical figures for Stipple-

Among the more terrestrial members of the genus *Myrmeciza*, the **Scalloped Antbird** spends most of its time in leaf litter.

It progresses with short hops, stopping regularly to shift leaves in the manner of a leaf-tosser (*Sclerurus*), usually with a vigorous sideways flick of the bill, sometimes by picking up a leaf and throwing it. Occasionally, it burrows its head under the leaves, or hops up to low perches to peer about before dropping back to the ground. The tail is often partially fanned, as here; it is also regularly dipped slowly, then flicked upwards more rapidly.

[*Myrmeciza ruficauda* soror, Alagoas, Brazil. Photo: Anita Studer]

Many antbirds are staunch inhabitants of the understorey, and rarely seek sunlight. Others frequent the canopy and have never been seen "sun-bathing", although they may well do so out of sight, high above the ground. Certainly, a few species that live in relatively open habitats are known to "sun-bathe" in a manner similar to most birds: an individual (in this case a **Stripe-backed Antbird**) pauses in a sunlit spot with feathers ruffled, and wings and tail variably outstretched. In general, such poses are seldom held for more than a minute or two before the bird snaps out of its trance-like state, sleeks its feathers, and moves back to the shade.

throated, White-eyed and Ornate Antwrens of, respectively, 94%, 99% and 98%. Similarly, various published and unpublished data sets record dead-leaf use greater than 90% for the Brown-bellied, Foothill, Rufous-tailed and Brown-backed Antwrens (*Myrmotherula fieldsae*), as well.

All these studies of dead-leaf-foraging guilds have found that most of the specialists are either ovenbirds or thamnophilid antbirds and, of these, most are understorey species. The rarity of extreme dead-leaf specialization among canopy and subcanopy species probably reflects the rarity of suspended dead leaves at those strata compared with the understorey. Among antbirds, the Spot-winged Antshrike is the only canopy or subcanopy species that uses dead leaves to a large extent, as it switches between bouts of dead-leaf and live-leaf foraging. In Rosenberg's study, it was recorded as exploiting dead leaves in 58% of foraging observations; it was also the only species for which dead-leaf foraging appeared to be height-dependent, as it searched dead leaves significantly more often when foraging in the understorey or mid-storey than when at higher levels. A number of other antbirds, at least in some parts of their range, are regular users of dead leaves. In Rosenberg's study, these included the Plain-throated, Ihering's and Dot-winged Antwrens and the Warbling Antbird, with relevant figures of, respectively, 50%, 47%, 26% and 31%, but the use of dead-leaf substrates by these species appears to vary regionally.

Dead-leaf specialists, including members of the "stipple-throated antwren assemblage", tend to move from one dead leaf or dead-leaf cluster to another, ignoring intervening areas of live foliage or other substrates. Because dead leaves are often suspended in places that are difficult to reach, they must employ a number of acrobatic manoeuvres in order to inspect the leaves. These include hanging from the margins of the dead leaves or sitting astride them, as well as clinging to adjacent vegetation and reaching, often while upside-down, to get at the leaves. Rosenberg found that what separated specialists and regular users from occasional users was the tendency of the former to manipulate dead leaves physically with the bill or feet. All specialists picked at dead leaves with the bill in at least 50% of their foraging attempts, often probing inside the curls and sometimes championing down on one end of the leaf to flush immobile or hidden

prey. These actions were often accompanied by head-cocking, as if to listen, and by peering inside the leaves. In contrast, non-specialists visually inspect leaves, usually briefly, but rarely manipulate the leaf as a means of aiding prey detection. In contrast to various furnariid dead-leaf specialists, no antbirds were found to use their feet to manipulate dead leaves. Many of the larger furnariids, as well as some woodcreepers and barbets (Capitonidae), tear apart leaves during their searches, effectively destroying those leaves as future hiding places for arthropods. The specialist antwrens usually leave inspected leaves intact, maintaining their potential as renewable resources.

In Rosenberg's studies, the diets of nearly all dead-leaf specialists were qualitatively similar, differing only in the proportions of the major prey taxa taken. Typically, most of the food, 64%-94%, consisted of orthopterans, cockroaches, beetles and spiders. In general, antwrens ate more cockroaches and spiders than did the various furnariids, and dead-leaf specialists among the antwrens ate a higher proportion of orthopterans and cockroaches than did the live-leaf foragers, which tended to take more larvae. Dietary diversity was lowest in the Stipple-throated Antwren, more than 50% of the consumed prey items of which were katydids or crickets. Ornate Antwrens took more spiders and heteropteran bugs (mostly Pentatomidae) than did the other antwrens. Antwrens generally did not take orthopterans larger than 20 mm, and virtually all beetles eaten measured less than 10 mm. Apart from orthopterans, which were preferentially selected by all antwrens, prey taken by the dead-leaf specialists were selected roughly in proportion to their availability. The arthropod fauna found in dead leaves consisted mostly of cockroaches and orthopterans, spiders and small beetles, with smaller numbers of colonial ants, heteropterans, wasps and flies, and some moths and larvae. The range of arthropods in live foliage was significantly different, with no cockroaches and fewer orthopterans and beetles, and with ants, heteropterans, flies and wasps more numerous. Among the antwrens studied by Rosenberg, the two live-leaf foragers, the White-flanked and Long-winged Antwrens, did not take prey in proportion to their abundance on live leaves; instead, they consumed many more beetles and larvae than expected, and many fewer ants, flies and wasps.

All antbirds are diurnal. At night they roost on narrow twigs at varying heights above the ground. Not surprisingly, it appears that canopy species roost in the canopy and understorey species, like this **Amazonian Antshrike**, roost lower down in shrubs and saplings. In the few instances for which details of roosting behaviour are known, antbirds appear to revisit traditional roost-sites night after night, arriving and departing at regular times, regardless of weather conditions.

[*Thamnophilus amazonicus amazonicus*, near Jenaro Herrera, Loreto, Peru. Photo: Mark Bowler/NHPA]

In Panama, the most commonly observed prey taken by Checker-throated Antwrens were orthopterans, cockroaches and spiders. Gradwohl and Greenberg conducted an experiment to determine if the Checker-throated Antwrens had a measurable effect on their prey populations. They used mesh enclosures to prevent the antwrens from foraging in selected areas, the mesh size being large enough to allow the passage of the largest insects, but too small for antwrens to pass through. Sampling of enclosures and control sites prior to the experiment revealed that the two did not differ in the fauna that they contained. Enclosures were maintained for six weeks, and both they and the control plots were then sampled, when it was found that arthropods inhabiting aerial leaf litter were nearly twice as common inside the enclosures as outside. This difference between controls and enclosures was assumed to be attributable to the Checker-throated Antwrens, as they were the only dead-leaf specialists present in the study site. These results suggest that, in a six-week period, a single bird species reduced the quantity of its preferred prey items by almost 50%.

Remsen and Parker found that syntopic dead-leaf specialists differed in body size, which presumably was reflected in differences in sizes of prey taken. There were also differences in the sizes of leaves examined by each one and in foraging height, or in their habitat preferences. At the lower-lying of the two study sites, White-eyed Antwrens and Ornate Antwrens occupied different habitats, with the former in forest and the latter in bamboo thickets. At the higher site, where White-eyed Antwrens did not occur, Ornate Antwrens were found in all forest types, as well as in bamboo thickets. Similarly, Rosenberg found that, within a habitat, most species differed from one another either in foraging height or in the average size of leaves searched. The most important way in which guild-members differed, however, was in the types of dead leaves that they exploited. White-eyed Antwrens in upland forest in Madre de Dios, Peru, and Stipple-throated Antwrens in upland forest in Pando, Bolivia, both fed frequently at understorey palm leaflets (e.g. *Geonoma*). In low-lying forest in Peru, Ornate Antwrens differed greatly from White-eyed Antwrens in making heavy use of dead bamboo leaves; at Pando, however, the White-eyed Antwren was the only *Myrmotherula* in bamboo, and there it fed frequently at dead bamboo leaves.

Furthermore, where the Ornate and White-eyed Antwrens overlapped in low-lying forest in Peru, they also differed significantly in average foraging height and in size of leaves inspected. In Gradwohl and Greenberg's studies of Checker-throated Antwrens, there were no potentially competing species of dead-leaf specialists. Checker-throated Antwrens were not constrained in their habitat selection, although they seemed to prefer vine tangles, where trapped aerial leaf litter was most abundant. They also used leaves at random, despite the fact that longer and more curled leaves were shown to contain the most arthropods.

Yet another novel resource available to tropical-forest birds results from the movements of army ants. The term "army ant" is most commonly used to refer to ants of the subfamily Dorylinae, group-raiding nomads that regularly change the location of their nest-site. These ants occur in tropical Africa and the Americas, and are represented in the Neotropics by the tribe Ecitonini. Although army ants of one species or another can be found from the United States south to Patagonia, most are underground or nocturnal raiders and, therefore, of little interest to birds. Other species raid above ground, but only on overcast days, and hence are unpredictable. Still others are regular surface raiders, but move in narrow columns that flush few prey, and, again, are of little interest to birds. One widespread Neotropical species, *Eciton burchelli*, is a diurnal swarm raider, fanning out along broad fronts containing hundreds of thousands of ravenous carnivorous ants. In the process, these flush large numbers of arthropods and small vertebrates, many of which are normally concealed in leaf litter. Ahead of the swarm await opportunistic birds and parasitic wasps and flies, ready to pounce on potential prey or hosts fleeing the ants. The birds do not eat the ants, although ants clinging to larger prey are occasionally ingested. Rather, the army ants provide an important service that greatly increases foraging efficiency. Instead of expending energy in systematic, time-consuming searching, the birds allow the ants to act as "beaters", which drive an abundance of prey right into their laps. An excellent example of the advantage provided to birds that forage over ants can be found in Willis's studies of Spotted Antbirds. Willis found that this species, when foraging actively at good ant swarms and away from competing larger species, tried for prey at an average interval of once every 32.3 seconds. By comparison, the average interval

After hours traipsing through the understorey of Amazonian rainforest without seeing much sign of life, an ornithologist can easily become slightly demoralized. The best antidote for this malaise is an antswarm. To watch a raiding carpet of ants accompanied by antbirds is a vivid and entertaining experience, especially because swarm-following birds are sometimes so engrossed in their feeding frenzy that they seem blithely unaware of human presence. The dark understorey suddenly comes to life with animated creatures, all hunting, churring, chasing and bickering in the pursuit of prey. This sequence of photographs was taken at an antswarm attended by **Bicoloured Antbirds**. It shows the range of poses adopted while these birds hunt. Unless displaced by competitors, they tend to perch at the swarm front, usually less than 1 m above the ground. Like most "professional" ant-followers, they are as adept at clinging laterally to slender vertical stems as they are at using horizontal branches. With their strong legs, they frequently jump from one stem to another, without using the wings. They display remarkable agility, pitching and swinging around perches, making split-second adjustments and darting down at great speed, according to the movements of the ants and the appearance of flushed prey beneath them.

[*Gymnopithys leucaspis lateralis*,  
Explorama Lodge,  
Quebrada Sucusari, Peru.

for Spotted Antbirds away from ants was 111.8 seconds, a nearly fourfold difference.

A number of species have evolved to specialize in foraging over army ants, to the point that virtually all of their food is obtained in this way. Most of these so-called obligate, or "professional", army-ant followers are members of the Thamnophilidae, although a few belong to the woodcreeper family. Other species are "regular followers" which routinely follow ants but often forage away from them, while others again rank only as "occasional followers". It is from the propensity of some thamnophilid species to follow ants that the name "antbird" is derived.

In order to appreciate how ant-following birds forage, one must first understand the basic biology and natural history of the ants, which was described by T. C. Schneirla for *Eciton burchelli*. The nest, or "bivouac", of the colony is a tightly bundled mass of hundreds of thousands of ants, tucked under a fallen tree, inside a log or hollow, or in some similarly sheltered spot. Inside the mass of workers and soldiers lie the queen and her broods. The reproductive cycle of the queen determines the activity cycles of the colony. So-called "statory phases", or "stationary phases", lasting about three weeks, alternate with "nomadic phases", which last about two weeks. The bivouac remains in a single location for the duration of the statory period, during which the queen lays her eggs. Meanwhile, the ants launch weak raids of short duration, often lasting only a few hours, or, on some days, make no raids at all. At the end of the statory phase the eggs hatch, producing masses of new larvae that must be fed. The colony then enters the nomadic phase, during which the bivouac is typically moved to a new location every night. It is during this period that the ants conduct massive daily raids, usually commencing shortly after dawn and lasting throughout the day. A nomadic raid begins when ants stream out of the bivouac and mass around it, before finally heading off in a single direction. The front of the swarm is often irregular, owing in part to irregularities of the terrain, and the swarm may temporarily split into two or more forks, which will eventually rejoin after less productive branches fold. Large swarms can measure more than 15 m across, with ants scurrying over and under logs and brush piles, through the leaf litter, and several metres up the bases of trees. Most prey are flushed along the swarm front, as cockroaches, crickets, spiders, beetles, sowbugs, other ants, and small lizards and frogs all run for their lives to escape the encroaching hordes. Behind the swarm front is the "fan", a broad network of ants racing in all directions, which eventually narrows to a "trail", along which ants carry back pieces of food to feed to the queen and her larvae. The average speed of 113 swarms watched by Willis on Barro Colorado Island, in Panama, was 14.8 m per hour. Nomadic swarms may move 200 m or more in a day, less on days when rains cause temporary cessation of raiding. Each night, the ants move the bivouac to a suitable new site along one of the trails made earlier in the day. The ants wander without regard for territorial borders, and at times two or more swarms can be within a few hundred metres of one another, whereas at other times there may be no swarms at all within a square kilometre. Various studies of army ants on Barro Colorado estimate an average of about three swarms per square kilometre. At the end of the nomadic phase, the developing larvae spin their cocoons, and the colony re-enters the statory phase. Once again, the queen will lay a new batch of eggs, which, by the end of the period, will hatch, coincident with the hatching pupae of the previous generation. Thus, a new generation of workers will be available to help to feed the newly hatched larvae, setting off the next nomadic phase. In this manner, nomadic and statory cycles alternate throughout the year, providing predictable foraging opportunities for ant-following birds.

Although *Eciton burchelli* is the army ant of choice among ant-following birds, other species are occasionally exploited. Birds regularly follow the smaller *Labidus praedator*, a swarm-raiding species that forms small but very dense swarms. This ant raids underground for much of the time, emerging on the surface mainly in the rainy season, which has earned it the name of "rain ant" in parts of Brazil. This seasonality may be a response to the cycles of isopods and amphipods, the primary prey items of *L. praedator*, which are rare in leaf litter during the dry season, but common during the rainy season. *Labidus* forages

mainly in more open parts of the forest understorey, where its preferred prey are more common; it tends not to forage so high into trees nor so much in dense tangles as does *E. burchelli*, and its raids seldom remain above ground for so long. It does not flush so many arthropods as *E. burchelli*, and its swarms are often more of an ancillary resource for ant-following birds when no *E. burchelli* swarms are nearby.

Among the Thamnophilidae, ant-following is most highly evolved in the seven genera *Rhegmatorhina*, *Phlegopsis*, *Skutuchia*, *Phaenostictus*, *Gymnophrys*, *Pithys* and *Pyriglena*. Of these obligate ant-followers, which total 18 species, only the three *Pyriglena* species, the fire-eyes, are ever regularly seen foraging away from ants. In addition to these 18, six other thamnophilids, in four genera, are "regular" ant-followers, but are just as frequently found away from ants: these are the Bare-crowned, Sooty, Immaculate, Black-headed, Spotted and Scale-backed Antbirds. Many more members of the family attend ant swarms occasionally, but seldom stay with them for more than short periods of time. Most of what is known about ant-following birds in general, and about the obligate and regular ant-following antbirds in particular, is due to the pioneering fieldwork and voluminous publications of Willis and Y. Oniki. Willis, especially, has conducted field studies of virtually all of the above-mentioned species, and the summaries included here, as well as the discussions of ant-following species in the following section (see Breeding), are based largely on his work.

Obligate army-ant followers begin cruising, or "wandering", in search of ants shortly after dawn. They generally move through the forest 1-2 m above the ground, flying 1-15 m at a time, and perching between flights on slender vertical stems, from which they peer about before flying rapidly to the next perch. Cruising birds often give loudsongs (see Voice), particularly when pair-members are visually separated. These songs carry for up to 300 m in the forest, and often draw responses from other species of obligate ant-followers, which may investigate the source of the songs in the expectation of locating a swarm of ants. Birds looking for ants often start by returning to bivouac sites or swarm sites of the previous afternoon. Once a trail of ants is located, the antbirds follow it to reach the head of the swarm. The birds probably stop at the first active swarm that they encounter in the morning, but also commonly shift from one colony to another and back. Colour-ringed White-plumed Antbirds have been found attending three different swarms on the same day, and regularly switch between swarms up to a kilometre or more apart. During the statory period of a given colony, antbirds often visit the bivouac site daily, despite the absence of swarming. Even after find-

Birds living in dimly lit habitats can be expected to employ vocalizations extensively for communication, and the antbirds are no exception.

Many have loud and distinctive vocalizations, and most, such as this Large-tailed Antshrike, are far easier to locate if their voice is known.

The sounds of antbird loudsongs are amongst those that serve to epitomize tropical forests in the New World.

São Paulo, Brazil.  
Photo: Edson Endrigo]

ing and switching to a nomadic colony, they may continue to visit a known statary colony, almost as if monitoring its progress.

Once a nomadic raid is located, the antbirds quickly settle into foraging. In the absence of competing birds, they move quickly to the swarm front, where most potential prey are being flushed. They perch usually less than 1 m above the ground, and often below 0.5 m. Most of the obligate ant-followers are equally adept at clinging laterally to slender vertical stems as they are at sitting astride horizontal limbs (see Morphological Aspects). In the typical posture, the upper leg is flexed and the lower leg extended. From these perches, the birds display remarkable gymnastic agility, as they pitch, roll or yaw in making split-second adjustments according to the actions of the ants and the flushed prey below. With their strong legs, the antbirds frequently jump from one vertical stem to another, without using the wings. The most frequent attack manoeuvres are sallies, involving a sudden jump or flight followed by capture, before landing; the second most common strategy is simple lunges from a perch.

Sallying antbirds snap up prey and bounce back quickly to a perch before the swarming ants can counter-attack. Willis found that, for Ocellated and Bicoloured Antbirds, over 75% of such sallies to the ground were over distances of within 0.5 m of the perch, and less than 1% were more than 2 m. At times, prey such as spiders and orthopterans may take extreme evasive action, making a series of bounding jumps or flights in order to escape both the birds and the ants, with pursuing antbirds following in a zigzag series of stops and starts, fluttering hops, or flights. Prey animals sometimes take refuge beneath the leaf litter, whereupon the antbird pounces on the spot and stands, splay-legged, as it tosses leaf after leaf with its bill in an attempt to uncover the arthropod. All the while, ants may be swarming over the feet of the bird, which often hops from one supporting foot to the other in a jittery attempt to dislodge the insects. Lunging birds often yaw or pitch to snatch prey with quick stabs of the bill from the ground or from stem or leaf surfaces. At other times, the antbird may fly or jump to the ground, or to a perch closer to the prey, before lunging. Occasionally, flying or jumping prey are snapped out of the air, or from overhanging vegetation.

There is no shortage of potential food at typical *Eciton* swarms. Willis found that Ocellated Antbirds, foraging away from

competitors at good sites over ants, darted for food at an average frequency of once every 38.5 seconds; the average for Bicoloured Antbirds was once every 42.6 seconds.

Most obligate ant-following antbirds deal with larger prey items in a manner that differs somewhat from that of other members of the family. Smaller prey, up to roughly the length of the bill, are routinely mandibulated slightly, if at all, and then swallowed whole. In the process of subduing and dismembering larger prey, such as long-legged orthopterans and spiders, the obligate ant-followers, unlike most other antbirds, seldom bash these against branches. Instead, they typically grasp the arthropod by an appendage and shake it vigorously, until the appendage and the body separate. Each appendage is eaten as it comes off. Once all of the legs are removed, the bird often separates the principal body segments, again by chewing and shaking. This process is often lengthy, lasting up to ten minutes or more for some larger items, and the antbird, in order to accomplish the task, usually retreats some distance from the main front of the swarm, away from other, competing birds as well as from the ants. After eating, the bird often wipes its bill on a branch before resumption of foraging. The pace at which large, energy-rich prey items can be caught is so rapid that the antbirds eventually show signs of satiation. They slow down the rate of sallying, and spend longer and longer periods in watching the action. Smaller prey that were readily taken earlier are now ignored, and only larger items are pursued. Handling times become longer, and birds often retreat to the periphery of the swarm to preen and rest.

The foregoing describes generally the foraging behaviour of the various species of *Gymnopathys* and *Rhegmatorhina* and, to a lesser extent, that of the other obligate ant-followers. There are some differences among species and genera. Ocellated Antbirds forage in much the same way as do *Gymnopathys* and *Rhegmatorhina* species; despite their large size, they cling readily, although rather less often, to slender vertical stems, selecting perches mostly below 0.5 m, and taking most prey by sallying or lunging. They forage from the ground more often than do the smaller obligate ant-followers. The Pale-faced Antbird is similar in its choice of vertical or horizontal perches, in its postures, and in capturing most prey by sallying to the ground and then quickly jumping or flying back to a perch. It is somewhat more sedate

Unlike that of oscine passerines, the syrinx of antbirds is rather basic in construction and the birds are thought not to learn their vocalizations.

The most noticeable songs of thamnophilids, the loudsongs, are therefore correspondingly uncomplicated and stereotyped. They usually consist of a series of simple notes, although the variety of ways in which these notes are shaped into clear whistles or raspy sounds, slowed down, or speeded up into trills, seems endless. The loudsong of the male **Stripe-backed Antbird** begins with one harsh note and ends, after a brief interval, with two longer whistles, each rising and falling in pitch.

[*Myrmorchilus strigilatus*  
*suspicax*,  
Salta, Argentina.

Calo]

Analysis of loudsongs has proved to be an important tool in determining taxonomic relationships in the antbird family. The loudsong of the **Brown-bellied Antwren** is a very rapid, high-pitched, musical trill initially ascending sharply in pitch and intensity, then gradually dropping again. This vocalization helps to corroborate the arguments based on morphology in placing the species in the "stipple-throated assemblage" of *Myrmotherula antwrens*. However, it is not only the loudsongs that are useful. A second, distinct vocalization is used in ritualized confrontations by all eight species in this assemblage, a fact which clearly supports their monophyly.

[*Myrmotherula gutturalis*,

VIREO]

than the smaller *Gymnopithys* and *Rhegmatorhina* species, and is more prone to foraging on the ground by hopping just ahead of the swarm. Willis described it as being semi-terrestrial when compared with *Gymnopithys*. The two species of bare-eye, in the genus *Phlegopsis*, forage in similar fashions, selecting horizontal and inclined perches as often as vertical ones. These large antbirds cling more awkwardly to vertical stems than do the smaller obligate ant-followers; they are less likely than Pale-faced Antbirds, but more likely than smaller antbirds, to forage from the ground. The *Pyriglena* fire-eyes prefer horizontal or slightly inclined perches to vertical ones, and forage most efficiently when ant swarms enter tangled undergrowth. They tend to move around the swarms more actively, rather than waiting for prolonged periods on a single perch as *Gymnopithys* and *Rhegmatorhina* are prone to do. The small Spotted Antbird is much like a *Gymnopithys* species in its foraging behaviour over ants, but it sallies more readily to take prey from the air or from above-ground vegetation. Scale-backed Antbirds, with their unusually long claws and toes, combined with a light body weight, are unique among the ant-following antbirds in perching crosswise on vertical trunks of more than 4 cm in diameter. Other antbirds perch on large trunks mainly if the perch angle is less than 45 degrees from the horizontal, and appear awkward and unable to maintain position on thicker vertical trunks. Scale-backed Antbirds make quick, darting sallies to take prey, and then fly off some distance to consume it. The White-plumed Antbird, the smallest of the obligate ant-followers, forages in a manner similar to that of *Gymnopithys* species, selecting vertical or horizontal perches very near the ground, and taking most prey by sallying to the ground. It regularly uses the thinnest perches, mostly less than 1 cm in diameter, and seldom sallies more than 0.3 m. It is distinguished by its exceptionally fast, darting movements in pursuit of prey.

Obligate and regular ant-followers have evolved morphologically and behaviourally to exploit the novel foraging opportunities provided by ants. With this specialization, they are able to outcompete more generalist species when foraging over ants. Specialization, however, has its costs. Birds that are dependent on nomadic ants for nearly all of their food must solve the problem of how to maintain territories and raise young. As the ant swarms wander without respect for boundaries, the presence of army-ant colonies near the nest of a pair of antbirds at a given

point in time is completely unpredictable. This uncertainty is compounded by the complex life-cycle of the ants, which are of primary value to the birds during their nomadic phase, when they make prolonged daily raids. The time required for the birds to progress from egg-laying to the fledging of young is much longer than the duration of the nomadic phase of any one colony of ants. Furthermore, with ants moving up to 200 m per day during their nomadic periods, any given swarm represents an ephemeral resource that quickly becomes impracticable to defend.

Both the English and scientific names of the **Warbling Antbird** refer to its vocalizations, and celebrate the fact that it is an off-heard species throughout much of its range. The choice of adjective, however, was unfortunate: the Warbling Antbird never warbles. The male gives a rather repetitive descending series of notes, starting off strident, becoming quickly rasping, and ending with a snarl. As with many antbirds, the female has a slightly different song (though still not a warble), which she often gives in a loosely co-ordinated duet, just before or after the male's song comes to an end.

In order to get around these problems, obligate ant-following antbirds have evolved alternative systems of social organization to the strict territoriality found in most species in the family. The exact system employed varies somewhat among different species and genera, but in all cases it involves a common theme. The *Gymnopathys* and *Rhegmatorhina* antbirds appear to be particularly similar in their social systems. The best-known of these species is the Bicoloured Antbird, which Willis studied for many years in Panama. Unmated Bicoloured Antbirds show few signs of territoriality or site-attachment and, instead, wander nomadically from swarm to swarm. Nomadic individuals may pair and continue a nomadic lifestyle, with the difference that they now accompany one another when moving between swarms. Nesting pairs show a high degree of site-fidelity, returning each time to the same area of previous nestings, regardless of the immediate location of ant swarms. These birds restrict their daily movements chiefly to an area within about 400 m of the nest, an area which, on the basis of ant densities at Willis's study sites, should at any point in time encompass an average of 1.3 *Eciton* swarms and 4 *Labidus praedator* swarms. They may, however, follow large *Eciton* swarms up to a kilometre away, sometimes even when there are swarms closer to the nest. In these cases, the birds either have not discovered the closer swarms or have abandoned them in favour of a more productive swarm. This roaming pursuit of the best ant swarms, regardless of distance from the nest, would not be possible if pairs maintained traditional exclusive territories. Although nesting areas, within which resident pairs are dominant, do not overlap, foraging areas overlap completely, so that any point in the forest is within the foraging range of several pairs of Bicoloured Antbirds. Thus, it is possible for several pairs or families, along with unmated single individuals, to congregate over the same swarm of ants. These birds may all follow the same swarm for several days, or some pairs or individuals may switch between different swarms. In any event, these are not social flocks but, rather, aggregations of competing birds independently drawn to a locally abundant resource. The sheer abundance of prey flushed at a large *Eciton* swarm is more than any one pair or family of antbirds could exploit, and the relaxing of territorial boundaries enables all pairs to benefit. Each pair can nest, secure in its access to sufficient numbers of raiding ant

colonies, and without the energetic burden of defending an exceedingly large territory. This loose territoriality promotes higher population densities, and allows unmated young birds to remain in areas in which all, or nearly all, of the available nesting territories are saturated.

For most obligate ant-following thamnophilids, the presence of more than one pair or family at a given swarm is the rule rather than the exception. Weak or irregular raids of statary colonies of *Eciton burchelli*, as well as raids made by smaller species of army ant, may be attended by lone individuals or pairs, but at most nomadic swarms two or three pairs or families will be present, with larger swarms attracting many more birds. The maximum number of individuals reported at a single swarm is 15 for Bicoloured Antbirds, 26 for Rufous-throated Antbirds, 16-20 for Fringe-backed Fire-eyes and 22 for Black-spotted Bare-eyes; peak attendance for most other species is somewhat lower. With large numbers of birds competing for the same prey, agonistic behaviour is to be expected. Each antbird attempts to maintain a clear zone, free of competitors, around itself; if unable to do so, the bird retreats to peripheral, more defensible parts of the swarm. Willis estimated that Bicoloured Antbirds defended an area of 0.3-2 m.

Fortunately, the social organization of each species lends some structure to what would otherwise become a completely chaotic situation. A Bicoloured Antbird in its nesting area is always dominant over other Bicoloured Antbirds, regardless of how many are present, and irrespective of the age, sex, behaviour or breeding status of the birds involved. The dominant pair at any given swarm is the pair that nests in that vicinity; if the resident pair is absent, then the closest neighbouring pair usually assumes the dominant position. In general, the closer a pair is to its nesting territory, the higher the position it occupies in the pecking order at swarms. Pairs foraging at great distances from their nesting areas, however, may find themselves subordinate to unmated birds that have established their position in the hierarchy at a swarm. All obligate ant-followers have evolved a complex set of vocalizations, postures and displays that are used to signal dominance and submissiveness to conspecifics. Under normal conditions, only the dominant individual or pair at a swarm noisily and intensely challenges an approaching bird. High-ranking neighbours may re-

The antbirds have successfully diversified in the Neotropics by exploiting the wide array of food supplies presented by complex habitats such as rainforests. One such food supply is contained within hanging dead leaves, where many insects and spiders lurk, or leave their eggs and young. Several antbird species specialize on this resource, concentrating up to 98% of their foraging time on searching dead leaves. The **Black-hooded Antshrike** is not a specialist, but it routinely visits suspended dead leaves in search of food, often sitting astride larger clumps, probing and tearing them vigorously with its bill.

spond with muted vocalizations, but subordinates typically move quietly to peripheral areas and direct their aggression towards still lower-ranking conspecifics, or towards other, more subordinate species. Working with individually marked Bicoloured Antbirds, Willis found evidence that reversals of dominance can occur across fairly narrow zones, sometimes as little as 10-30 m, and that dominance areas form a mosaic that lacks appreciable gaps unless a pair disappears. In numerous instances, he observed reversals of dominance when ant swarms moved from the nesting area of one antbird pair to that of another. A pair that was dominant for several days suddenly became subordinate as the ants moved into the nesting area of a second pair, with the situation being reversed again a few months later when the swarm moved back through the nesting area of the first pair.

The closer two individuals come to each other at a swarm, the more likely supplantings or displacements become. A supplanting bird takes the perch of another by flying at it, whereas displacement involves a bird moving away or performing escape or submissive behaviour when approached by another. A mated individual will even displace or supplant its partner when it approaches closer than 1-2 m, and birds that are less accustomed to one another will frequently extend this zone of "personal space" by supplanting at greater distances. Violent outbursts of vocalizations and displays routinely occur when new birds arrive at attended swarms, and these serve mainly to signal position in the pecking order. Dominant antbirds typically take the central sites over the swarm front, where the most prey are usually flushed, with subordinates relegated to peripheral parts of the swarm, which can also include vertical displacement to higher, less productive perches. In addition, dominant individuals are usually conservative in their foraging strategies, clinging to vertical perches and sallying to the ground, with relatively infrequent changes of position. Subordinate birds, on the other hand, are more active, exploring different side branches of the swarm, and more frequently climbing about in tangles of vegetation and perch-gleaning from or sallying to vegetation. Only subordinate birds steal prey from ants that are carrying food back to the bivouac.

Ocellated Antbirds have the most complex social structure of any obligate ant-follower. Young of this species, although fre-

quently wandering from the natal territory, continue to associate with their parents long after the latter have stopped feeding them. Patrilineal clans develop around a successful pair, forming family groups in which young males and the mates that they recruit are tolerated both during and outside breeding seasons for several years. These clans can separate or come together as food supplies dictate. Young females typically remain on their natal territories until the breeding season after the one in which they hatched, and then leave to mate outside the clan. Large clans can contain eight or more individuals, and clan-members bunch together, shoulder to shoulder, in disputes with other clans. Up to four pairs or families of Ocellated Antbirds may be found at the same ant swarm, and, as with the Bicoloured Antbird, the pair in its own nesting area dominates over all others, with similar changes of dominance when swarms cross nesting-area boundaries. Nevertheless, since Ocellated Antbirds have much bigger nesting areas, about 1500 m across, and occur in lower densities, the "dominance cores" are large and sufficiently diffuse that some pairs may never move far enough beyond their nesting areas to become subordinate. When present in higher densities, Ocellated Antbirds occur not only as "main" pairs, but also in what Willis refers to as "superimposed" pairs, the simplest type of which is a young male offspring of the main pair along with his mate. This superimposed pair co-occupies the territory of the main pair, and together they form the nucleus of a clan.

Although Ocellated Antbirds are dominant over all other antbirds at swarms, their intraspecific interactions include more submissive postures and displays than aggressive ones, a fact which allows subordinate individuals to remain in close association with the dominant pair of the group. This lack of intraspecific aggression can be seen in pairs of Ocellated Antbirds, which often forage from the same perches, sometimes with their bodies touching. This is in stark contrast to Bicoloured Antbirds, an individual of which will readily supplant its own mate if the latter invades its zone of "personal space". Female Ocellated Antbirds are smaller than males, and are subordinate even to trespassing males unless their own mates or older sons are present. A female dominates over other females at swarms if she is near her own territory. At swarms attended by multiple pairs or clans, dominance hierarchies often come into play whereby individuals force

All antbirds feed primarily on a wide variety of insects and other arthropods. The **Plain Antvireo** is a generalized perch-gleaner, often accompanying mixed-species flocks and taking prey directly from both surfaces of living leaves, as well as vines and thin branches. Its diet, as far as is known, includes adult and larval beetles and, as here, lepidopteran larvae; it also takes katydids, true bugs and spiders. Only very rarely has it been observed to feed on non-arthropod food, such as the berries of mistletoe (*Rapanea*).

[*Dysithamnus mentalis mentalis*, Iguazú, Misiones, Argentina.

Photo: Julián M. Alonso]

out lower-ranking birds, whether of the same clan or of a different one. Because of the well-developed submissive behaviour among subordinates, these expulsions may be accomplished with a minimum of aggression.

Unlike the preceding species, the Spotted Antbird maintains fixed territories and seldom leaves them. This thamnophilid, even though it attends army-ant swarms, appears not to be part of the clade of obligate ant-followers (see Systematics). At ant swarms within his territory, the male Spotted Antbird is dominant over all other conspecifics, but again, as with Bicoloured Antbirds, there is a reversal of dominance as soon as the male crosses into the territory of a neighbour, regardless of the respective ages of the two birds. Spotted Antbirds regularly attend ant swarms while these are passing through their territories, but they are likely to desert the ants once they have moved into another Spotted Antbird's domain. This species' ability to forage away from ants allows it to maintain rigid territories, something that would be impractical for obligate ant-followers. In complete contrast to Ocellated Antbirds, Spotted Antbirds rarely display submissive behaviour. A trespasser, as soon as it appears at a swarm, is challenged by the resident bird and almost immediately supplanted. It may return repeatedly, but with the same results, and eventually it is either driven off completely or banished to peripheral zones.

All but the most dominant species modify their behaviour over ants when in the presence of competing ant-followers. In general, large obligate followers dominate over smaller obligate followers, as well as over most similarly sized or smaller regular and occasional followers. Within its range, the large Ocellated Antbird is, therefore, the dominant thamnophilid at swarms, with the Bicoloured Antbird being subdominant, and the small Spotted Antbird relegated to the periphery or to making brief, infiltrative raids into the centre of the swarm. In the Guianan region, the

largest obligate follower is the Rufous-throated Antbird, which thoroughly dominates over the smaller White-plumed Antbird. In much of Amazonia, the dominant antbird at swarms is one of the two species of bare-eye or, if neither is present, the local species of *Rhegmatorhina*. Within its small range, the large Pale-faced Antbird typically dominates over all other antbirds. These dominant species control the central zone near the swarm front, which produces the most prey, and they actively supplant or displace subordinate species from this zone.

Subordinate species occupy zones away from the swarm front, the distance increasing in accordance with the position of each in the dominance hierarchy. As with subordinate individuals within a species, they may be displaced to higher perches as well as horizontally, to less preferred foraging stations. A variety of strategies has been adopted by the various subordinate species among the regular and obligate ant-followers. In eastern Amazonian Brazil, White-backed Fire-eyes are always subordinate to Black-spotted Bare-eyes, which frequently target them for attack. The arrival of bare-eyes at a swarm centre causes the fire-eyes to disperse to the periphery or to forage much higher above ground. The fire-eyes maintain near-constant motion, hopping around the edges and sticking to any adjacent areas of dense cover. Were they to remain stationary or in the open, this would invite an attack from the bare-eyes. Black-headed Antbirds pursue a similar strategy when foraging at swarms dominated by Rufous-throated Antbirds, where they are regularly supplanted and seldom allowed to forage over the centre of the swarm; as they are neither fast enough nor agile enough to infiltrate the ranks of the Rufous-throated Antbirds and woodcreepers which dominate the swarm centre, they tend to remain on the periphery, hopping in and out of denser cover. The Lunulated and White-throated Antbirds, in the absence of larger species such as the Reddish-winged Bare-eye, Hairy-crested Antbird and Sooty Antbird, forage in the same way as do the two bigger *Gymnophithys*; when dominant birds are present, however, they are readily displaced to higher and more peripheral zones. The small Scale-backed Antbird adopts a different strategy. It generally avoids confrontation altogether, by either deserting swarms attended by larger antbirds or remaining so far out on the fringes as to avoid any attention; occasionally, individuals may briefly infiltrate the outer zones of swarms, but typically they retreat considerable distances to consume any prey caught. The White-plumed Antbird is also small, but it takes an entirely different tack, relying on its extreme speed and agility repeatedly to infiltrate the innermost zones of a swarm, snatch

Like most antshrikes, the **Barred Antshrike** is a somewhat generalized gleaner, moving through foliage with heavy hops, pausing regularly for prolonged periods (sometimes up to a minute or more), and actively scanning for prey. It often seems ponderous and slightly ungainly, but it is lethally quick when it spots a beetle scuttling along a branch. As well as insects, some antshrikes, especially the Barred, are known to eat seeds and fruit on occasion.

[*Thamnophilus doliatus*, Colombia.  
Photo: Thomas McNish/VIREO]

Closely associated pairs or family groups of **Black-faced Antbirds** are usually found foraging 0-2 m above ground in the slightly open understorey of terra firme, or less often floodplain, forest in Amazonia. They mostly travel independently, away from mixed-species flocks, feeding on a variety of insects and other arthropods; this male has caught a spider.

[*Myrmoborus myotherinus elegans*, Explorama Lodge, Quebrada Sucusari, Peru.  
Photo: Jordi Bas]

prey from under larger species, and retreat just ahead of the inevitable attack. It persists in returning again and again to productive spots, despite being constantly supplanted and assaulted by one or more dominant species. Throughout its wide range, the White-plumed Antbird is subordinate to and systematically attacked by nearly every regular or obligate ant-follower with the exception of the slightly smaller Scale-backed Antbird.

As Willis noted, subordinate ant-followers tend to be non-social, apparently because they are often forced to forage at marginal sites, and because they cannot afford to attract the attention of dominant species by conspicuous vocalizations or displays. In spite of this, large aggregations of subordinate species can be found at some swarms, but these individuals are mostly unrelated and antagonistic towards one another. Accordingly, the subordinate species have not evolved the elaborate submissive postures and displays that help to maintain pecking orders among aggregations of dominant and subdominant obligate ant-followers.

Unfortunately, aside from the intensive studies of relatively few species, some of which are noted above, there remains little in the way of detailed published information on the foraging behaviour of most antbirds. Over the past two decades, a number of fieldworkers have gradually accumulated a wealth of new information, including data on foraging, for many Neotropical birds, the Thamnophilidae among them, but much of this remains unpublished other than as brief summaries in popular field guides. Part of the problem stems from the sheer number of species and the relatively few researchers. Many of the most active and experienced researchers, the very people who know the living birds and their habits best, choose to seek new discoveries rather than to write up their existing knowledge. A bigger part of the problem, however, is that the editors of many technical journals now routinely reject foraging information that has not been rigidly quantified, on the grounds that only quantitative data sets are objectively and statistically comparable. Recently, Whitney and Pacheco, in a thoughtful counterpoint to such thinking, made the point that there are a large number of variables inherent in any study of foraging behaviour. Among these are seasonal, temporal or weather-related fluctuations in composition, abundance, spatial distribution and behaviour of potential prey species; variations in numbers or densities of various foraging substrates at different strata within a forest or between sites; observer-related effects on the foraging behaviour of the birds; and possible seasonal behavioural shifts based on the current reproductive condition of the birds. None of these variables is easily quantified, yet,

unless their effects are taken into account, it is unlikely that any quantified data sets on foraging are comparable. In addition, data collected by individuals of varying skill levels, at different sites, or at the same sites in different seasons or years, and using different definitions and methodologies, defy many of the assumptions on which statistical analyses depend. This is not to argue that quantified studies are not useful and desirable. Nevertheless, the acceptance of the applicability and comparability of differently quantified data sets which fail to address the many possible variables could result in misleading conclusions in studies of systematic relationships and comparative ecology.

This having been said, there remain potential pitfalls in blanket acceptance of unquantified data. Sample size is an important consideration, as is geographical breadth. Care must be taken to avoid extrapolating too much from a few observations, or from more extensive observations of a species in a single locality. Consistency among observations of different fieldworkers is an important control. Keeping these conditions in mind, it seems preferable to include such unquantified data, this being far more informative than saying nothing at all. For many Neotropical birds, even the most basic aspects of natural history, such as nest descriptions and foraging behaviour, are unknown, and the publication of carefully descriptive natural-history information provides a heuristic springboard that can ultimately result in more structured and detailed quantitative studies.

### Breeding

So far as is known, nearly all antbirds are monogamous, pair for life, and defend territories throughout the year. In an eight-year study of colour-ringed Dusky Antbirds in Panama, for example, Morton and B. J. M. Stutchbury found that pair-bonds were permanent, the average adult mortality rate was only 17%, and 72% of territories had the same boundaries as existed when their occupants were first ringed. When mates were experimentally removed from their territories (see Voice), new pair-bonds were in some cases formed within a matter of minutes, although some individuals, of both sexes, remained unpaired for the two-month duration of the experiment. Similarly, Willis found that pair-members of the White-backed Fire-eye commonly remained together throughout the 14 months of his study; as in the Dusky Antbird experiment, however, both males and females remated rapidly if the partner disappeared, as occurred when forest clearance in one corner of the study area led to the dissolution of some pair-bonds.

The *Great Antshrike* is perhaps the most opportunistic of all antbirds. It is one of the few that regularly eat snails and slugs, and it sometimes preys on small rodents. In the Pantanal region of Brazil it is regularly seen foraging in drying marshes, where it uses the leaves of water hyacinths as platforms from which to fish for tadpoles and minnows.

Photo: Joe Fuhman]

Two exceptions to typical antbird life histories have been found, and both involve obligate ant-followers (see Food and Feeding). One is the White-plumed Antbird, which could be considered "serially monogamous". When White-plumed Antbirds fledge two young, each parent cares for one of the fledglings (see below). When only one young is reared, it is almost invariably cared for by the male, at which time the female typically begins to accept food from another male, and very quickly begins reneesting with a new mate. Willis found such "divorces" to be common among White-plumed Antbirds, with females quickly changing mates even when the first one was still alive. He suggested that this comparative inconstancy of pair-bonds may be strongly linked to the relative lack of territoriality in the species. As subordinate obligate ant-followers (see Food and Feeding) that depend on infiltration, White-plumed Antbirds wander so widely that females gain little by staying with the same male and learning his territory. Another, particularly intriguing species is the Black-spotted Bare-eye, which is currently being studied by S. Willson-Hillman in an attempt to determine whether it departs, at least occasionally, from strict monogamy.

Most antbirds hold territories in the classic sense, although exceptions include some nuclear species of mixed-species flocks and virtually all obligate ant-followers (see Food and Feeding). Territories are usually defended throughout the year, by both members of a breeding pair, with agonistic displays, vocalizations, chases and attacks usually directed at trespassers of the same sex. Those of some species are surprisingly small and those of others very large. The territory size of Manu Antbirds has been estimated at 0.5-1 ha at one site in Bolivia and 0.2-0.5 ha at some sites in Brazil, and K. J. Zimmer estimated territories of Yapaana Antbirds in Venezuela to be no more than 50-75 m in diameter. At the other end of the spectrum are the larger species of obligate ant-follower, such as the Ocellated Antbird, which can have home ranges measuring in excess of 1500 m in diameter. Field observations suggest that the territory size of Giant Antshrikes may be even greater. *Myrmotherula* antwrens, many of which are habitual followers of mixed-species flocks, often have territories that are much larger than their small size may suggest. Gradwohl and Greenberg determined the territory of a pair of Checker-throated Antwrens to be 2.3 ha, whereas

those of White-flanked Antwrens were two or three times larger; the Checker-throated Antwrens, however, were found to use a small portion of their territory for a disproportionate amount of time, spending 67% of their time in just 18% of the territory. The extent to which other antbirds may use their territories in a similarly patchy way is not known.

The most common prelude to pair formation and copulation is courtship feeding of the female by the male. This has been documented for many thamnophilid species, and may be common to all members of the family. The duration and extent of courtship feeding probably vary considerably among species and among individual pairs within a species. Nesting by Bicoloured Antbirds is always preceded by several days to several weeks of courtship feeding, during which the female gradually stops foraging for herself and becomes dependent on the attentions of the male. In the early stages, a male brings food mainly after he has satisfied his own hunger. Eventually, he provides the female with nearly all of her food, feeding her before he has fed himself. It seems likely that this degree of attention would not be possible without the relatively abundant foraging opportunities provided by army-ant swarms (see Food and Feeding). Courtship feeding by antbirds that do not follow ants may be somewhat less intense, and of shorter duration. With Bicoloured Antbirds, copulation is usually limited to the last few days of the courtship-feeding period. After the first copulation, females resume feeding themselves. Courtship feeding, as it becomes more sporadic, is more likely to end in copulation than is the case earlier in the period.

Little is known of the behaviour associated with nest-site selection. Willis and Oniki have recorded nest-showing behaviour for Bicoloured Antbirds and Rufous-throated Antbirds. During the last week or two of courtship feeding, the pair often wanders away from ant swarms to search for potential nest-sites. The male frequently initiates this by flying to the top of a hollow stub or some other suitable location, where he proceeds to tail-flick, posture, deliver repetitively a form of the softsong (see Voice), and toss wood chips or dead leaves out of the cavity that he is showing. The male may nest-show at inappropriate sites, but, when a particularly good one is found, he intensifies his actions. Females also search for sites, and may perform similar showing behaviour to bring a site to the attention of the mate.

**Pairs of Rusty-backed Antwrens** usually travel in close association, foraging in the interior of shrubs, small trees and tall grasses. Like other Formicivora species, they are active foragers, progressing by dainty hops and fluttery flights, pausing frequently to scan for insects. These they catch by perch-gleaning with quick stabbing motions of the bill, or by quick horizontal lunges; they also make short sallies to pluck prey from the underside of overhanging vegetation. While foraging, their posture is generally horizontal with the tail half-fanned and cocked slightly above the plane of the body.

Willis has also described a "draping" display by male White-backed Fire-eyes, which appears to be used to show possible nest-sites to the female. In this display, the male drapes himself over a perch in a limp manner, while conspicuously flaring his white interscapular patch; the neck is protracted and the head held low, with the facial feathers in some cases ruffled and in others sleeked.

Nest construction has been observed for relatively few species of antbird, and in detail for even fewer. So far as is known, both sexes share in building the nest, although, for at least some species, the contribution of the male appears to be the greater. Over a two-hour span, a pair of Dusky Antbirds, watched by Skutch, made 46 trips with nesting material, 29 of these by the male and only 17 by the female. In observing the construction of nine nests of Spotted Antbirds, Willis noted a ratio of three male trips for every female trip; at one nest, the male made 21 trips to the female's ten over a 113-minute period. Skutch noted similar behaviour by Plain Antvireos. Willis found that White-backed Fire-eye males take the initial role in nest-building, with females contributing to the addition of the lining much later in the process. Most extreme were the Black-crested Antshrikes observed by F. Haverschmidt in Surinam, where, in 2.5 hours of observation, the male made 28 trips with nesting material and the female only six. Conversely, a male Dot-winged Antwren, in 2.5 hours of observation by Skutch, made only one visit more than his mate.

Some of the most comprehensive observations of nest-building come from Oniki's studies of Western Slaty Antshrikes in Panama, which suggest that the male and female contributions towards nest construction are almost equal. In nearly 67 hours of observation, she found the median interval between visits to be 4 minutes for the male and 5 minutes for the female; the maximum interval for the male was 147 minutes and for the female 153 minutes. Between arriving and leaving, males spent between 3 and 360 seconds in adding material and working on the nest, while females spent between 8 and 480 seconds. The average time that males spent on the nest in any one trip was 57.3 seconds, compared with 77.8 seconds for the females. Males made more trips, but spent less time per trip. Of a total of 140 visits, 45 were made by the male alone and 26 by the female alone; on 69 occasions, both male and female visited the nest together.

Most species seem to gather the bulk of nesting materials from within 50 m or so of the nest-site. Those which habitually forage with mixed-species flocks tend to work on their nests more sporadically, making trips only as the flock is passing near the nest-site. Various observers have noted the tendency for antbirds to devote more time to nest construction in the middle of the day than in the early-morning hours. The time required to complete a nest varies considerably from species to species, and also, probably, among individual pairs within a species. Skutch watched a pair of Plain Antvireos complete a nest in less than two days, but noted times of five to six days for Black-hooded Antshrikes, more than eight days for a pair of Checker-throated Antwrens, and nine to ten days for a pair of Russet Antshrikes. Oniki found that nest construction by Western Slaty Antshrikes commences about ten days before egg-laying. For many, if not most, species, there is a break of at least two days between nest completion and laying of the first egg, although the birds frequently add bits of fine, filamentous material to the lining even after incubation has begun.

The architecture of antbird nests not only provides fascinating natural history, but also offers a potential insight into phylogenetic history (see Systematics). Broadly speaking, antbird nests can be described as either "suspended" or "supported". Of the thamnophilid nests described to date, the most common type in numerical terms is a suspended open cup with a diameter equal to or greater than its depth, composed of vegetable matter such as grasses, twigs, dead leaves and plant filaments, and often lined with "vegetable horsehair", a blackish fungus (*Marasmius*) that resembles horsehair. Most often, these cup-nests are suspended by the rim from a horizontal fork in the outer branches of a tree or shrub, but sometimes they are slung from two touching branches which at the point of crossing resemble the bifurcation of a single branch; rarely, they are hung from two parallel branches. Suspended open cup-nests are built by antshrike species in the genera *Frederickena*, *Taraba*, *Sakesphorus*,

*Thamnophilus*, *Xenornis* and *Thamnistes*, by the "grey antwren assemblage" of *Myrmotherula*, by the Rufous-bellied and Plain-throated Antwrens, by the *Herpsilochmus*, *Microrhopias* and *Formicivora* antwrens, and by the Banded Antbird, the "nigricans group" of *Cercomacra* antbirds, the Spotted and Spot-backed Antbirds and the Wing-banded Antbird. Of all of these species, the Speckled Antshrike is the only one that is known to build its nest entirely of rootlets, although some species appear to construct cup-nests entirely of moss or lichen. In addition, in Panama, the Wing-banded Antbird has also been recorded as placing a new lining inside an old Western Slaty Antshrike nest that had been preyed on six months earlier.

Typically, the height above the ground at which these nests are placed corresponded to the foraging height of the species. Canopy-inhabiting *Herpsilochmus* antwrens, for example, place their nests high in the canopy and subcanopy.

Nests composed almost entirely of fine plant filaments are often so thin-walled that the contents are visible through the bottom of the cup. Such a loose construction may facilitate drainage and ventilation, important considerations in the humid and often very wet environments that many antbirds occupy. Cup-nests are frequently described as "deep" or "shallow", but such adjectives are not useful in characterizing antbird nests. Descriptions that include dimensions are needed in order to understand whether there is any constant and meaningful variation in the construction of suspended cup-nests.

Some species decorate the exterior of the suspended nest, usually with either dead leaves or moss, the material in some cases extended into a dangling "tail" that can hang a considerable distance below the cup. The use of bright green moss is particularly prevalent among antvireos of the genus *Dysithamnus*,

The largest antshrikes, such as the **Undulated Antshrike**, tend to have larger and more hooked bills which equip them for handling larger prey items such as orthopterans, mantises, and even small vertebrates. Antshrikes are known to catch and devour small lizards (mostly *Anolis* species, but also geckos), as well as frogs and snakes. When the item is a large insect, many antbirds will repeatedly beat it against a branch before methodically using the bill to remove any undesirable wings, legs or urticating spines.

[*Frederickena unduligera fulva*, Allpahuayo-Mishana Reserved Zone, Loreto, Peru.  
Photo: José Álvarez Alonso]

A small subset of thamnophilid species are known as "professional" ant-followers because they spend almost their entire lives following ants. Of the many New and Old World birds that follow ants, only a few woodcreepers (Dendrocolaptidae) match them in their nearly complete specialization in ant-following. This remarkable lifestyle has given the English name to the entire family. Of the true ant-followers, the **Bicoloured Antbird** is one of the commonest; here it is pictured on a low perch with the ground beneath it covered in army ants. These ants are diurnal, carnivorous, swarm-raiding nomads; huge numbers of them fan out along broad fronts hunting arthropods and small vertebrates, many of which are normally concealed in leaf litter and low vegetation. To escape the ants, these small creatures abandon their shelters and camouflage, and it is this mass of fleeing prey that attracts the antbirds. They wait at the head of the swarm, ready to pounce. Apart from the obligate army-ant followers, there are other species termed "regular ant-followers", which routinely follow ants but often forage away from them, while others again rank only as "occasional ant-followers".

[*Gymnophaps leucaspis*, Soberania National Park, Panama.

Photo: Marie Read]

This **Bicoloured Antbird** has successfully gleaned a morsel from the path of an antswarm. Regardless of whether they are "professional" ant-followers or not, most antbirds forage more efficiently at swarms than away from them. In the **Spotted Antbird** (*Hylophylax naevioides*), it was found that, when they hunted alongside swarms, individuals experienced a four-fold improvement in foraging efficiency, or at least a four-fold increase in foraging opportunities. This explains why so many species opportunistically join swarms when these pass through their territories.

which often not only cover the nest with this material but also leave a tail of it hanging from the bottom, thereby making the nest appear even more like a suspended clump of moss. The only known nest of the Pearly Antshrike had numerous dead leaves partially woven into the bottom of the cup in a messy fashion, and similar nests have been described for the Dusky-throated Antshrike. Further, the single known nest of the Scaled Antbird was a basket hanging from two parallel branches and with a "tail" of dead leaves five times longer than the height of the nest. It seems reasonable to assume that decorations serve to disguise nests by making them look like natural formations of vegetation.

The suspended nests of some antbirds are much deeper pouches that are more purse-shaped than cup-shaped, and most, if not all, of these are decorated. Three *Cercomacra* species of the "tyrannina group" have been found to build such nests. The Dusky Antbird, for instance, constructs a deep, pensile pouch with an oblique opening near the top, with thick walls of dead leaves, plant fibres, dead grass blades and strips of palm fronds, suspended by fungal strands from the fork of a slender, drooping tree branch, vine or climbing fern. One such nest was covered with green moss, with embedded long shredded fern stems, some hanging 46 cm below the nest, so that the whole resembled a ball of moss. Species of the "stipple-throated group" of *Myrmotherula* antwrens have a similar type of nest, this being most clearly evident in that of the Checker-throated Antwren, a deep, pensile pouch with an oblique opening, built largely of dead leaves and fine filaments. Nests of the closely related Rufous-tailed and Brown-bellied Antwrens have been described as being similar to the last, but more dome-shaped or oven-shaped, composed mostly of dead leaves and with a side entrance, and placed in small understorey saplings. Deep pouch-nests are also built by *Drymophila*, *Hypocnemis* and *Hypocnemoides* antbirds, although a few individual nests of these species have been described as a deep cup and, in one case, as approaching a dome in shape. Two additional groups of antwrens build nests that may fall into this category or into the previous one. Known nests of the "streaked antwren group" of *Myrmotherula* are typically likened to a bag covered with moss, and the dimensions available for one species suggest that they form a pouch rather than a cup. Only two nest descriptions are available for *Terenura* antwrens and these are

conflicting, even though the two species involved are closely related; one was described as a cup and the other as a pouch.

A number of other antbirds build cup-nests that sit atop substrates, rather than being suspended or pendent. Such nests account for about one-third of known thamnophilid nests, or 36 of 112 species. Supports include branches in trees; hollows along the basal portions of trees formed by vines wrapping around the trunk, by the junction with the trunk of leaf rachides or sheaves of small palms, or by epiphytic ferns; hollows in dead stumps and natural cavities of live trees; and dense vegetation such as a clump of sedge, root tangles, and leaf litter on the ground. Some thamnophilid species employ more than one of these types of support, although in such cases the situations are closely similar. Of all these supported nests, those resting on branches appear to be the least common. The nest of the Giant Antshrike has been described as a very large cup untidily made of stalks, grasses, *Tillandsia*, leaves and fibres, like that of a *Turdus* thrush, and placed on a solid base of branches. The Cinereous and Bluish-slate Antshrikes construct a deep, leafy cup entirely of dried rotten leaves, rhizomorphs and fine rootlets, and internally lined with finer plant fibres and dried leaves. They build this into aerial piles of leaves and debris accumulating at junctions of large branches of live and fallen trees, but they also use similar accumulations along trunks of palms and other large-leaved trees and between the tree trunks and vines. The exterior of such nests presents a disarrayed appearance that simulates a pile of dead leaves lodged in the understorey. The only known nest of the Spot-winged Antshrike looked like a pile of large leaves, similar to a Cinereous Antshrike nest; it was under construction in a tangle of branches up in a tree, where it could not be determined whether it was suspended or supported, although it appeared to be resting on branches.

As noted above, nests of Cinereous and Bluish-slate Antshrikes are often placed along trunks of palms and other trees, usually within a few metres of the ground. Where they join the trunk, rachides of fronds and spines of small palms, especially of the genera *Bactris*, *Oenocarpus*, *Sheelea* and *Astrocarum*, provide attractive nesting sites. Antbirds that take advantage of such sites seem often to use other sites as well. Two deep cup-nests of Plumbeous Antbirds were found attached to palm spines, and

So far as is known, nearly all antbirds are monogamous, pair for life, and defend year-round territories that are often stable in position and dimension, year after year. Within these territories, antbirds usually attempt to breed between one and three times annually. The accompanying portraits show adult **Scalloped Antbirds** (the male above) at one of the few nests ever described. These nests have all been hidden cups placed on the ground, constructed primarily of dead leaves, and lined with *Marasmius* fibres, fine stalks or leaf veins. They were all placed on platforms of dead leaves; two were situated in tangles of sedges; one was partially covered by the leaves of a shrub and bordered by a vine; the one seen here was the most open in location. In general, the most terrestrial antbirds, like this species, can be expected to nest on or close to the ground.

[*Myrmeciza ruficauda* soror, Alagoas, Brazil.  
Photos: Anita Studer]

This is a predator's eye view of the male **Scalloped Antbird** incubating at the same nest as in the previous photos. Despite the fact that the nest is not covered, and despite the illumination provided by a camera flash, the sitting bird is very inconspicuous. As with virtually all birds, the efficient concealment of nests is vital in maintaining reproductive success above the threshold necessary for survival.

another was placed among the fronds of an epiphytic fern. A White-shouldered Antbird nest was a deep cup partially covered with leaves and placed between the leaf rachides of a palm. Cup-nests of the Scale-backed Antbird have been found against trunks at the bases of palm fronds, but also in hollow stumps and on the ground; the possibility has to be considered that various populations of this widespread species utilize different kinds of nest-site. White-plumed Antbird cup-nests have been found sunk deep in debris on the growing tops of small palms less than 2.5 m tall, but also in the midst of sedges and herbs just off the ground. Shallow cup-nests of Hairy-crested Antbird have been discovered not only in palm-frond sheaths left on the trunk after the fronds have dropped, but also inside a stump. These examples suggest that antbirds which nest in hollows and recesses in vegetation close above the ground are flexible and opportunistic in the type and location of the space that they utilize.

Palms, along with trees of other families, also function as nest-sites when their trunks are broken off, leaving a hollow stump where debris collects. It was in this type of location, where the still extant rachides of palm leaves joined the stump, that the only known nest of the Bare-crowned Antbird was found, built of twigs, leaves and strips of palm fronds that were arranged to form a dome. In addition to the two species mentioned in the previous paragraph, the *Gymnopithys* antbirds nest in hollow stumps or stubs, and one atypical nest of the Bicoloured Antbird was in the hollow end of a large, upturned, fallen palm leaf. These nests often have a thin lining of rhizomorphs, to which the birds may continue to add through the incubation period.

Finally, a large number of antbirds nest on or just off the ground in leaf litter or other organic debris, tree roots, ferns or low herbaceous vegetation. Ground nests of antbirds of the genera *Pyriglena*, *Myrmoborus* and *Pernostola*, and a probable one of *Rhopornis*, have been described as oven-shaped or domed; typically, the nest is a sphere of leaves, petioles, twigs and/or rolled sheaths of bamboo, with finer fibres in the inner layers, and with an entrance to one side and sometimes at an angle above the horizontal. These nests are usually raised slightly off ground

level by being placed on a bed of debris, fallen branches, roots, a slight rise in the terrain or, in one case, the remains of an old nest. Many *Myrmeciza* antbirds also build on or near the ground, some of them constructing an open cup; other species, however, partially cover the cup with leaves, and, as F. A. Wilkinson and U. R. Smith carefully described, the Sooty Antbird extends the leafy cover to form a sphere and adds a short entrance tunnel. The one known nest of the Black-throated Antbird, a cup, was found, remarkably, sunk into a clump of sedge surrounded by water. In drier country, the only documented nest of the largely terrestrial Stripe-backed Antbird was an open cup of dry grasses, placed on the ground.

As noted in the preceding paragraphs, many of the low-lying supported nests of antbirds are covered, forming what have been described as domes, chambers, partially roofed cup-nests, and the like. For a number of genera, however, sample sizes are too small and most descriptions too vague for the nest architecture to be classified with sufficient certainty for use in systematic studies. Improvement of knowledge of antbird nest architecture is an important task for future field ornithologists.

Almost all antbird species normally lay two eggs, with individual clutches of one or three eggs being rare. Three eggs do, however, represent a typical clutch of the Variable and Rufous-capped Antshrikes, and possibly of the Great Antshrike, in the southern portions of their ranges in Argentina, extreme southeastern Brazil and southern Bolivia. These species make seasonal movements in some of these regions (see Movements), and larger clutch size is perhaps an adaptation to the risks inherent in migration. The Wing-banded Antbird in the monotypic genus *Myrmornis* may normally lay just one egg; in French Guiana, Tostain found one nest with a single egg and has observed eleven pairs of Wing-banded Antbirds escorting single fledglings, many of them not yet capable of flight.

Antbird eggs are larger at one end than at the other. They have a ground colour varying from white to light pink and to buff, and with variable amounts of brown, reddish, maroon, purple, grey or black spotting, blotching, streaking, scrawling or other

markings, sometimes evenly distributed, but more often concentrated in a wreath around the larger end. For the few species the nesting of which has been studied, the normal pattern seems to be for eggs to be laid two days apart, with incubation commencing upon completion of the clutch.

Both sexes develop brood patches and share in incubating the eggs. So far as is known, only females incubate during the night. The male usually relieves the female early in the morning, and incubates for a prolonged period. This is followed by one or more midday rotations, before the male takes over for a lengthy afternoon shift. Some time before dusk, the female returns and settles on the nest for the night. In seven species of antbird studied by Skutch, the number of diurnal incubation sessions ranged from two, one by each sex, in one pair of White-flanked Antwrens and three, two by the male, in the Great Antshrike, to ten, of which seven were by the male, in the Dusky Antbird. Male and female Spotted Antbirds took three sessions apiece, whereas males of the Plain Antvireo and the Western Slaty Antshrike each took one more turn than their mates. There was a larger disparity between male and female Chestnut-backed Antbirds, in which the males took five shifts and the females only two. In the case of the Great Antshrike, incubation stints by males ranged from 146 to 238 minutes and one stint by the female lasted 239 minutes. At one nest of White-flanked Antwrens a single shift by the male was 134 minutes long and one by the female at least 33 minutes, while at another nest the male incubated for 3 to at least 174 minutes and the female for 98-140 minutes. For other species, the time ranges of incubation shifts, in minutes, for males and females, respectively, were 33-142 and 53-66 for Western Slaty Antshrikes, 103-147 and 41-79 for Plain Antvireos, 11-153 and 79-124 for Dusky Antbirds, 45-95 and 92-136 for Chestnut-backed Antbirds, and 44-217 and 36-164 for Spotted Antbirds. The largest discrepancy between the sexes in total amount of time dedicated to diurnal incubation was found in the Plain Antvireo, the male's contribution being 325 minutes more than the female's. Conversely, the male Spotted Antbird spent only 11 minutes more in daytime incubation than did the female. In the other species studied by Skutch, the discrepancy ranged from 145 minutes in the Great Antshrike to 95 minutes in the White-flanked Antwren. When the unbroken nocturnal shift of the fe-

males is taken into account, however, the female contribution to incubation remains as the more significant one.

Skutch also tracked intervals of neglect at each of the above nests. In the 11 hours of observation at the Great Antshrike nest, the birds left their eggs unattended only once, for a period of 17 minutes. This translates into 97% attendance, calculated as the percentage of time for which the eggs were incubated during the period between the end of the female's nocturnal shift and the beginning of the next one. The Plain Antvireo pair left its clutch unattended eight times, totalling 45 minutes, giving 95% attendance. Other attendance values were 94% for Western Slaty Antshrikes, 76% for one pair of White-flanked Antwrens and 50% for the other pair, 82% for Dusky Antbirds, 87% for Chestnut-backed Antbirds, and 92.5% for Spotted Antbirds. Of these, only the White-flanked Antwren stands out as having significantly lower nest attendance than the other species. This may be linked to its habit of foraging with mixed-species flocks, which takes it to distant parts of its territory for long periods of time. None of the other species studied by Skutch was a habitual flock-member. For obligate army-ant followers, patterns of incubation can probably be deduced from the presence or absence of one member of a known pair at ant swarms.

Oniki has contributed some of the most comprehensive data on the incubation behaviour of thamnophilids. In her study of Western Slaty Antshrikes in Panama, she found that the two sexes contributed nearly equally to daytime incubation. She noted one particularly long session, when a female remained on the nest for 4 hours and 33 minutes, from 12:42 to 16:55 hours; on the next day, the male incubated from 11:45 to 15:27, whereafter the female took over and sat from 15:28 until 06:58 hours on the following morning, a phenomenal shift of 15 hours and 30 minutes. Willis and Oniki found that sitting antshrikes sometimes called from the nest during long incubation sessions. In a similar study of Chestnut-backed Antbirds, they noted that daytime incubation sessions lasted up to 217 minutes for the female and over 236 minutes for the male, with respective averages of 119 and 113 minutes; recesses ranged from 1 to 117 minutes, and averaged 16.5 minutes. The female incubated for 40% of the daylight hours and the male for 48%, and nest attendance was 88%, increasing to 93% in the last eight days before hatching. In a study of White-

Breeding in antbirds is an egalitarian endeavour. Both sexes contribute to nest-building, sometimes in equal measure, although it is often the male whose contribution seems greatest.

This male **Slaty Antwren** is inspecting his work: a deep cup of black fungal rhizomorphs, thinly woven, bound by cobwebs, and suspended by its rim from a couple of branches. While this structure is typical of the "grey antwrens", the "stipple-throated antwrens" use dead leaves to build a deep, pensile pouch, and the "streaked antwrens" tend to make neater, mossier, more bag-like pouches. Nest design can provide useful taxonomic clues.

The **Uniform Antshrike** is fairly common and widely distributed in the Andean forests of Colombia, Ecuador and Peru.

Despite being relatively abundant and easy to find, almost nothing is known about its breeding biology. Indeed, these photographs are the only details on record.

It is worth noting, however, that from these two images we can deduce some useful information. First, we can note that the species has placed this nest low down in tangled vegetation.

Second, we can see the basic structure of the nest: a deep suspended cup of fibres (normal for the genus *Thamnophilus*), surrounded on the outside with a layer of moss, which is probably added to provide both insulation and camouflage. Third, we can tell that the male contributes to incubation.

Fourth, we can see that on this occasion, at least, the clutch consists of two eggs, as is normal for almost all antbirds.

Fifth, these eggs are creamy white with numerous large blotches and small spots of brownish-purple, lavender or red, clustered loosely into a wreath encircling the blunt end. Details such as these help to build a picture of reproductive strategies, nest design and egg characteristics throughout the family, a picture that is starting to provide useful insight into natural history and taxonomic relationships. This example serves as a reminder of just how little is known about the basic biology of South American birds, and it underscores the important contribution that can still be made by field ornithologists.

In common with most *Myrmeciza* antbirds, the **White-bibbed Antbird** builds its nest on or near the ground, usually in a clutter of dead branches or on a thick mat of leaves. In structure, the nest is an untidy bowl of plant stems and fibres, very loosely woven, and randomly interposed with the leaves of trees and bamboo. The finish is deliberately ramshackle, and clearly an adaptation for camouflage: the nest resembles nothing more than a heap of fallen debris. Even the pale supercilia and boldly tipped coverts of the incubating female, so striking in the field, seem to mimic the lines and broken tips of twigs, thus breaking up her outline.

[*Myrmeciza loricata*, Penedo, Rio de Janeiro, Brazil.  
Photo: Dante Buzzetti]

backed Fire-eyes in Brazil. Oniki found the average incubation interval by females to be 205 minutes, while the figure for males was 148 minutes; female fire-eyes incubated for 48.5% of the daylight hours and males for 41.6%.

As with so many aspects of reproductive biology, the incubation period is not known for the majority of antbirds. For those for which information is available, a period of 14-16 days, calculated from the onset of incubation, is typical. Known exceptions include the Great Antshrike, with an incubation period of 17-18 days, and the Checker-throated Antwren and the Dusky Antbird, for both of which the period is 18-20 days. The last two have a deep pouch-nest that perhaps allows a longer incubation period, with lower risk of predation. When disturbed from the nest, incubating antbirds often drop to the ground and perform frantic, fluttering distraction displays. Those species with white interscapular patches flare these, an effective way of catching a would-be predator's attention. When the young hatch, the parents carry the eggshell fragments away from the nest and discard them.

In contrast to the young of formicariid ground-antbirds, which are covered with down at hatching, thamnophilid antbirds hatch naked, helpless and blind. The skin colour varies from dark pink to dusky grey and to nearly black. In some species, the eyes remain closed for the first two or three days, while in others, such as the Spotted Antbird, the nestlings may open their eyes late on the same day as they hatch. By the day after hatching, the buds of pin-feathers may be visible through the thin skin; by the second or third day the first pin-feathers are erupting, and they grow rapidly. Feather development is usually faster on the dorsal surface than on the ventral surface. The two parents share in brooding the young. As with incubation, only females brood during the night, and by day male antbirds tend to brood more than do females. Brooding attentiveness is highest during the first few days, when the naked young are incapable of regulating their own body temperature. For example, one or the other adult of a pair of Chestnut-backed Antbirds watched by Willis and Oniki brooded for 84% of the diurnal hours on the first day after hatching. At this

time, each feeding trip by either parent is usually followed by a brooding session. Faecal sacs of nestlings are typically consumed by the parents in the first two days, but thereafter are carried away from the nest and discarded.

Daytime brooding sessions diminish in frequency and duration with each passing day, until they eventually cease. In the case of the Chestnut-backed Antbirds studied by Skutch, brooding decreased by the sixth day, and at one nest there was no brooding at all on the eighth day. For Western Slaty Antshrikes, Oniki found a similar marked reduction in brooding after day 6, with no diurnal brooding after day 7 or 8. Great Antshrikes, however, continue daytime brooding through at least the ninth and tenth days. Females continue to brood through the night, even after daytime brooding has been discontinued.

Both parents share in the task of feeding the nestlings. Typically, they deliver larger prey to the nestlings, a habit that may reduce the number of required feeding trips to the nest and, therefore, decrease the risk of drawing the attention of predators. The parents usually remove and eat the appendages and head of larger prey before delivering them to the chicks, particularly during the first few days after hatching. Oniki observed that the two sexes of Western Slaty Antshrikes provided similar food, except that females captured grasshoppers more often, and males caught caterpillars or larvae more often; she also found that males tended to bring larger prey items than did females. It is not known if similar sexual differences in the types and sizes of prey brought to nestlings exist among other species of antbird, but such resource-partitioning is known to occur in many other families of birds.

At 13 nests of nine thamnophilid species monitored by Skutch, the combined feeding rates of the parents ranged from one trip per hour at one nest each of the Great Antshrike and the Black-hooded Antshrike, to 5.3 trips per hour at a Plain Antwren nest. The male and female seldom visit the nest simultaneously to feed nestlings. Typically, one parent makes a trip and then, depending mainly on the age of the nestlings, either stays to brood or leaves, with the other parent making a separate trip

Some antbirds decorate the exterior of their nests, usually with dead leaves or bryophytes, or both.

**Plain Antvireos**, like other members of the genus *Dysithamnus*, seem particularly inclined to use fresh moss.

They sometimes extend this material into a "tail" that dangles below the cup, thereby increasing its similarity to the myriad other clumps of moss hanging in the forest.

In this species, both sexes develop brood patches and take turns incubating the eggs. It is thought that the overnight shift is always undertaken by females, while males counterbalance their lack of nocturnal input by doing the bulk of incubating in daylight.

These observations match those for a variety of species throughout the family, although in many cases the contribution to diurnal incubation is roughly equal despite the females' incubating at night.

The **Rufous-winged Antshrike** is typical of the genus *Thamnophilus* in that both sexes co-operate to build a suspended cup-nest low above the ground, in a fork between branches. The construction process can take up to 13 days. During this time, the walls of the nest are solidly woven from fine grass stalks, rootlets and black *Marasmius* fibres, sometimes with the incorporation of flowers, bits of moss and bark fibre, or even on occasion man-made oddments such as wool, twine and balls of cotton. Although both sexes incubate the eggs, the male seems to invest most time incubating during daylight while the female incubates overnight. After 15 days, the eggs hatch.

[*Thamnophilus torquatus*, Alagoas, Brazil.  
Photos: Anita Studer]

At the same nest, this male **Rufous-winged Antshrike** is delivering food to his young. As well as dividing the burden of incubation, both sexes of most antbirds share the task of providing nestlings with food. Typically, adults devour any small food items that they find, and only deliver larger items directly to the nest. This habit reduces the number of required feeding trips and, therefore, decreases the risk of attracting the attention of predators. If the food item is particularly large, the parents usually remove and eat any appendages, such as wings or heads, before delivering the juicier portion to the chicks.

some time later. Oniki recorded low feeding rates by both sexes of Western Slaty Antshrikes prior to 08:00 hours and again after 16:00 hours. Presumably, this reflects a need by the adults to spend some time in the early morning in replenishing their own nutrient reserves following a night without feeding, as well as the need to store energy before roosting for the night. It may also be influenced by lack of light in the forest both early in the morning and late in the afternoon, making insects difficult to see and, therefore, diminishing foraging efficiency. Feeding rates for White-backed Fire-eyes were also low in the morning, but rates at each nest differed from one day to the next. They did not increase significantly as the young grew, with periods of 49, 63 and 50 minutes between feeds on the first three days at one nest, and 25, 36, 39, 24, 25 and 23 minutes between food deliveries on six consecutive days at another nest. This contrasts with the behaviour of Spotted Antbirds observed by Willis, who found that feeding rates increased greatly after the hatch day, but decreased slightly on the last day before fledging. At six nests, the average of 19 intervals between feeds of two nestlings by both parents was 18 minutes on the day of hatching; 43 such intervals on days 4 and 5 averaged 11 minutes, 67 intervals on days 6 and 7 averaged 12.5 minutes, 88 intervals on the next two days averaged 5.6 minutes, and 38 intervals on days 10 and 11 averaged 9.4 minutes. High feeding rates on days 8 and 9 were associated with the parents foraging near the nest. During the time when these nests were watched, male Spotted Antbirds made 185 feeding trips, compared with 108 by females. Visits by the two sexes were nearly equal up to the fifth day, with 44 by males and 47 by females; at all but one nest, however, female attentiveness waned thereafter, females making 61 visits, as against 141 trips by males. Oniki recorded a similar general pattern in the feeding rate of Rufous-throated Antbirds: the number of feeds averaged 1.4-1.5 per hour until the nestlings were 5-6 days old, then increased in the morning to 3.3-4.4 per hour until the young were 8-9 days old, before decreasing again to a rate of 1-1.8 per hour until the chicks fledged, at 13-14 days. Willis recorded feeding behaviour at a nest of Bicoloured Antbirds observed over

53.6 hours: 68 intervals between feeds by the male averaged 38 minutes in duration, with a similar figure of 41 minutes for 52 feeding intervals by the female; ten intervals between feeds when the nestlings were 1-2 days old averaged 43 minutes; and the average of 120 intervals when the young were 7-13 days old was 19 minutes, with little daily variation.

Some species may greatly accelerate feeding rates under certain circumstances. At a nest of Dusky Antbirds observed by Skutch, both parents remained away for 101 minutes, an exceptionally long time for no feedings. When finally the female arrived, she fed the nestlings, and she proceeded to make five more feeding trips in the next 24 minutes, during which time the male also returned and began accelerated foraging trips. In 69 minutes, the young were fed 17 times by the female and six times by the male, a combined rate of 20 feeds per hour, which was more than four times the average that Skutch had previously recorded at this nest. At the peak of food delivery, the parents made nine visits in 15 minutes. Willis and Oniki found that Spotted Antbirds also greatly speed up the rate at which they deliver food after the first nestling fledges. At one nest, the male attended to the first fledgling, leaving the female to tend the remaining chick, which did not leave the nest until the following morning; on that final morning, the brooding female slipped off the nest at 06:15 hours, and began feeding the nestling at a pace of once every 2.9 minutes from 06:31 until 07:01, at which point the young bird left the nest. Apart from this exceptional sequence, 30 intervals between feeds at other Spotted Antbird nests where a single parent fed one remaining nestling averaged 10.7 minutes in duration, barely longer than the average figure when both parents are feeding two nestlings. The chick that remains in the nest is essentially fed at almost twice the rate that it was before its sibling left, even though only one parent is doing the feeding.

In the Thamnophilidae, the nestling period is seemingly more variable than is the incubation period. It may last up to 13 days in the case of the Great Antshrike and 15 days for the Bicoloured Antbird, but can be as short as 8-9 days for the White-flanked, Dot-winged and Rusty-backed Antwrens. The size of the adult

bird is not always directly correlated to the length of the nestling period: the average period for the small Spotted Antbird in Costa Rica is 11-12 days, longer than that for the much larger Black-hooded Antshrike, which is 10-11 days.

In the few species for which fledging has been studied, the young usually leave the nest separately, at intervals ranging from minutes to a day, the slightly older sibling probably being the first to leave. In response to calls of one or both parents, a nestling calls back, and then hops up on to the rim of the nest, where it balances for seconds or minutes, sometimes stretching its wings, before fluttering to the ground. The attending parent immediately coaxes it away from the nest and into protective cover. From this point onwards, the fledgling is cared for exclusively by the parent that was present at the moment of its departure from the nest. The other parent assumes sole responsibility for the remaining nestling, and, as was demonstrated by Spotted Antbirds, may greatly accelerate its rate of food-provisioning, hastening the development and departure of the second chick. Brood division probably simplifies the task of keeping track of scattered nestlings that are hiding in dense vegetation, and, by allowing the young to disperse, probably also reduces the risk of predation of the entire brood. Because the breeding cycles of most antbirds remain unstudied in any detail, it is not known if brood division is the rule for the entire family. It is the case for the Western Slaty and Black-hooded Antshrikes, the White-backed Fire-eye, and the Black-headed, Chestnut-backed, Spotted and Bicoloured Antbirds.

When there is only one fledgling, either as a result of predation or because only one egg was laid, it is normal for one parent to assume most or all of the responsibility for it. Willis found that, in 15 cases in which only one fledgling White-backed Fire-eye survived, the adult female was the primary guardian of the young bird in twelve instances, whereas the male took on this role in only three cases. Conversely, males of White-plumed and Spotted Antbirds were more likely than females to be the primary guardians of sole surviving fledglings. With the Wing-banded Antbird in French Guiana, how-

ever, both parents accompany the single fledgling, both before and after it is able to fly.

Upon leaving the nest, young antbirds usually remain relatively immobile in the concealing cover of the undergrowth for the first few days. As they become stronger, and more capable of flight, they may, at the urging of their parents, be led to safer stations much higher above ground. The adults of species that normally follow mixed flocks may leave the fledglings to forage for a time with the flock, returning eventually to feed them. Oniki has recorded bob-tailed young Western Slaty Antshrikes feeding with their parents in mixed-species flocks just five days after fledging. At 28-32 days out of the nest, the young antshrikes, one of which was moulting from brown female-like plumage to grey male plumage, were still being fed frequently by the parents, and at 38-42 days they foraged clumsily in mixed-species flocks with them. Gradually, the young catch more and more of their own food, and leave their parents soon after the latter stop feeding them. With Western Slaty Antshrikes, this occurs about 50-60 days after leaving the nest. In the case of the White-backed Fire-eye, it is probably about 30 days after the start of incubation when the young first appear at ant swarms. At this stage they are still short-tailed, but nearly of adult weight, and already have their adult colours (black in males, brown in females). They tend to remain in cover near the periphery of the swarm, and are fed by their parents. By 15 days later, the tail is grown, and they often hop and forage clumsily near the ants, but still obtain most of their food from their parents. By another 15 days later, the young fire-eyes are obtaining most of their own food, but some individuals will continue to be fed, at least occasionally, some 45 days after abandoning the nest.

Juveniles of many antwrens may remain with their parents even longer. Skutch recorded juvenile Checker-throated Antwrens associating with their parents for up to three months, and a juvenile Dot-winged Antwren still begging at four months. Gradwohl and Greenberg observed immature White-flanked, Checker-throated and Dot-winged Antwrens associating closely with their parents even after the adults had started to nest again,

In contrast to the young of ground-antbirds (Formicariidae), which are covered with down at hatching, thamnophilid antbirds hatch naked, helpless and blind. The skin colour of hatchlings varies from dark pink, as in this **Slaty Antwren**, through dusky grey to nearly black. By the day after hatching, the buds of pin-feathers may be visible through the skin; after two or three days the first pin-feathers erupt, and thereafter they grow rapidly. For the first few days after hatching, the chicks are almost constantly brooded. As with incubation, both parents share in brooding, the females brooding at night, and males usually contributing more time during the day.

[*Myrmotherula schisticolor schisticolor*, Monteverde Forest Reserve, Costa Rica. Photo: Michael Fogden/Animals Animals]

Typically, the nest of the **White-backed Fire-eye** is a bulky sphere of dried leaves, petioles, twigs and sometimes rolled sheaths of bamboo, accessed by a side entrance. The whole structure is usually raised slightly above ground level by being placed on a bed of debris, fallen branches or roots. The oven-like design is unusual amongst antbirds, and is found in two other genera that are thought to be closely related to the fire-eyes: *Myrmoborus* and *Rhopornis*. This is one example in which similarities in nest architecture support the taxonomic conclusions drawn from analyses of morphology. Both parents feed the nestlings, arriving with food approximately every 50 minutes for one chick, or every 25 minutes for two chicks. As well as insects, the adults are known to bring small lizards to the nestlings, but only when the latter are more than 4 days old.

[*Pyriglena leuconota pernambucensis*, Alagoas, Brazil.

Recent field studies have shown that nestling **Black-hooded Antwrens** are brooded by both sexes, and receive a diet of small caterpillars and other arthropods. After 10-11 days, they are ready to leave the nest. The Black-hooded Antwren is the subject of a remarkable conservation story. After an absence of records spanning over one hundred years, the species was rediscovered in 1987. Despite spending much of the intervening century languishing in the wrong genus, and despite being erroneously thought of as a montane bird, it had survived all along on a heavily populated stretch of coast in south-east Brazil. These facts go to prove how easily antbirds – even ones as distinctive and attractive as this – can be overlooked, especially if people happen to be looking in the wrong direction! Through the efforts of those field ornithologists that strove to relocate it, and then through the work of conservationists, biologists and photographers, the Black-hooded Antwren has finally been rescued from anonymity. This portrait of an adult male feeding his offspring is a tribute to their efforts, and a symbol of hope, not only for this species, but for many other elusive birds that have so far evaded rediscovery.

[*Formicivora erythronotos*, Rio de Janeiro, Brazil.

or had raised other broods. This was especially true of White-flanked Antwrens, pairs of which were often accompanied by recently fledged juveniles, as well as by older subadults from the previous brood. The known extreme in the duration of parent-young bonds among the Thamnophilidae is found in the complex clan system of the Ocellated Antbird and the apparent second-year helpers at the nest of Black-spotted Bare-eyes (see Food and Feeding).

Willis's studies of Bicoloured Antbirds reveal a complex transition from fledging to independence. When young of that species first leave the nest, they hide in dense foliage well removed from the ant swarms at which their parents feed. The adults commute to and from the swarms to feed the fledglings, each parent assuming responsibility for just one of its offspring. By two weeks after leaving the nest, the young have grown sufficiently that they can alight on vertical stems without falling off. They now begin to follow their parents, which encourage them with "leading" behaviour. In addition to specific vocalizations, leading may involve the deliberate showing of food items to young in order to attract their attention, after which the adult flutters to another perch in an attempt to entice the young forward. Finally, the fledglings are led to the edge of ant swarms, where, at four weeks after leaving the nest, they forage clumsily alongside their parents, while often continuing to beg for food. At this age they have poor powers of discrimination, and frequently peck at still objects such as knots on tree roots or tips of twigs, and pick up and carry around small twigs or leaves. Slowly, the youngsters begin to peck at slow-moving arthropods such as sowbugs, and eventually to sally after larger and faster-moving prey. In all supplanting encounters (see Food and Feeding) the young bird is subordinate, except when these encounters involve its sibling. Older birds do not even waste time in "challenging" obvious juveniles, but supplant them without postural or vocal prelude. The longer the young bird remains at the swarms and forages for itself, the more it is subjected to supplanting attacks by older birds. If the juvenile begs from the "wrong" parent, the one other than that which has attended it since fledging, it is likely to be supplanted. Bicoloured Antbirds fledge with a brown belly, in glaring contrast to the white-bellied adults, and three weeks later they begin the transition to adult plumage, becoming gradually whiter on the underparts. As this transition progresses, the parents be-

come increasingly hostile toward the young, and frequently supplant them. Willis noted antbirds seven and eight weeks after fledging being regularly supplanted by their parents, but also, at least occasionally, being fed by them. Conversely, one juvenile, when it was only six weeks past fledging, started to follow a different swarm from that attended by its parents. After independence is achieved, the young bird wanders from swarm to swarm, maintaining a nomadic existence until such time as it is able to attract a mate.

The time between successive nestings by the same pair of antbirds is largely dependent on the outcome of the first nest. A pair that successfully fledge its young will be occupied for anything from weeks to months with the feeding and care of the still maturing fledglings. Pairs that lose the clutch or brood to predators or to some other disaster typically reneest as quickly as possible. Oniki monitored a pair of Western Slaty Antshrikes that had three unsuccessful nests between late June and late August. The interval between the loss of one nest and the commencement of the building of the next one was one day and, at most, four days; for the second and third breeding attempts, respectively, the interval between the loss of the previous nest and the start of the next clutch was about 14 days and about nine days. In Trinidad, a pair of Plain Antvireos was incubating at a second nest only 12-15 days after the first nest had been preyed on, and laying in a third nest followed 26-28 days after the eggs in the second nest had been lost. Pairs of Spotted Antbirds have been recorded as starting construction of a second nest within five to seven days of the last fledgling from the previous brood achieving independence, and pairs will, in some cases, begin reneesting even before the previous brood is fully independent. When Spotted Antbirds lose a nest to predation, the pair reneests immediately, within four days in two recorded cases. The interval between loss of a nest and reneesting is about ten days for White-backed Fire-eyes studied in Brazil. In the same population, the interval between a successful nest and reneesting is about 50 days. As with fire-eyes, White-plumed Antbirds regularly nest more than once per year, and Black-crested Antshrikes in Surinam have been documented as nesting twice in the same year, using the same nest. Conversely, Willis never found Bicoloured Antbirds to nest successfully twice in the same year, although pairs which lost a nest to predation made repeated attempts to

Research on the **Black-hooded Antwren** concluded that slightly less than one egg in four was likely to end up producing a fledgling. This, however, does not signal the stage at which the parents' duties end. In the few species for which the fledging stage has been studied, the young usually leave the nest separately. After fluttering down from the nest's rim, the first fledgling is immediately coaxed towards protective cover by its parent. From this point onwards, it is cared for exclusively by the adult that was present at the moment of its first flight. The other adult assumes sole responsibility for the remaining nestling, even after it fledges.

[*Formicivora erythronotos*,

Although the **Squamate Antbird** is endemic to the Atlantic Forest Lowlands EBA, it is not considered threatened with extinction. This is because it is generally fairly common and appears to flourish in selectively logged forest. Moreover, it occurs in several protected areas, such as the Serra da Bocaina National Park and the Serra do Mar State Park, as well as some privately protected properties such as Fazenda Capricornio, near Ubatuba, and Fazenda Intervalles, near Capão Bonito. Continued protection of these parks and reserves should ensure the long-term survival of this species.

[*Myrmeciza squamosa*, Cantareira, São Paulo, Brazil. Photo: Edson Endrigo]

renest; the interval between loss of a clutch or brood and the laying of the first replacement eggs varied from five to 19 days.

Nest success is generally low among antbirds, as is the case for most small forest birds that nest near the ground. Predation is the major factor in breeding failure, but, since it is rarely observed, the identity of the predators is open to question. The most frequent ones are likely to be snakes, and these are suggested as the culprits whenever the contents of a nest disappear without signs of disturbance to the nest, and without a trace of feathers or eggshell fragments. Mammals, particularly nocturnal ones, have also been implicated in many instances of predation on antbird nests. Unlike snakes, which swallow nest contents whole and leave the nest intact, mammalian predators typically rip the nest apart in their efforts to get at nestlings, eggs or sitting adults.

Most of the studies of nest success and predation of thamnophilids have been conducted in Panama. Unfortunately, many of these are from Barro Colorado Island, which, like other forest fragments, has artificially high rates of predation (see Status and Conservation). In one study of Western Slaty Antshrikes on Barro Colorado, only 10% of 32 nests successfully fledged one or more young. Results were better in a study in mainland Panama, with 46% of 54 nests successful in one year and 21% of 81 nests in the other year, although these percentages drop to 40% and 19% respectively if only those nests found during the building, laying or incubation stage are considered. Spotted Antbirds on Barro Colorado Island suffer heavily from predation: in one study, only six of 24 nests found before or during egg-laying reached the hatching stage; altogether, only 16 broods of young were reared from 84 nests found at various stages and followed until the outcome could be determined. Conversely, nest success of this species at sites in mainland Panama varied from 38% to 50% over two years; for those nests found in the building, laying or incubation stages, the figures were 28% and 39% for the two years. Ocellated Antbirds had particularly low success on Barro Colorado, with 87% of recorded nests unsuccessful. In one study from mainland Panama, no more than two out of 20 nests of Dusky Antbirds fledged young, with 17 of the remaining 18 being preyed on, while only 22.2% of 18 White-flanked Antwren nests were successful. Success of Checker-throated Antwren nests varied from 27.5% to 30.8% over two

years, but was lower, 14.3-25.5%, if only those nests found during the building, laying or incubation stages were counted. Similarly, of eleven nests of Dot-winged Antwrens, four fledged young, six were preyed on, and the outcome of the other was unknown. Chestnut-backed Antbirds fared equally poorly: young were successfully reared from only one of four nests in Costa Rica and from just one of six in Panama.

Unfortunately, there are very few comparable studies of nesting success of antbirds outside Panama and Costa Rica. In a study of Barred Antshrikes in Argentina, 33% of nests failed, while all five nests of Blackish-grey Antshrikes found in French Guiana were lost to predation, with arboreal snakes suggested as the likely predators.

The eight-year study of Dusky Antbirds by Morton and Stutchbury in mainland Panama revealed that the probability of reproducing successfully was no more than 8%, although varying substantially from year to year. The annual survival rate was 82%, and those authors concluded that a long lifespan was the key to lifetime reproductive success.

Brood parasitism by Shiny Cowbirds (*Molothrus bonariensis*) has been reported for Collared Antshrikes in Ecuador and Peru, and for Great, Rufous-capped and Variable Antshrikes in Argentina and southern Brazil. Most thamnophilids, however, being birds of the forest interior, probably do not suffer such problems from cowbirds. Nestling antbirds are subjected to a different type of parasitism, in the form of parasitic flies and biting insects. Nestling White-backed Fire-eyes and Black-spotted Bare-eyes have been found to be particularly common hosts of botfly larvae (Gasterophilidae), possibly because the type and location of their nests provide the humid micro-climates that are especially attractive to mosquitoes and parasitic flies.

For most of the Thamnophilidae the time of first breeding is not known, but it is probably about one year. Females of some of the obligate ant-following species have been found to breed earlier than males. Female White-plumed Antbirds, for instance, probably breed for the first time when they are only 6-8 months old. Even more precocious are female Bicoloured Antbirds, which regularly pair when they are just 4-6 months of age; Willis found one female which paired and produced eggs when she was only six-and-a-half months old. In contrast, male Bicoloured Antbirds

normally remain unpaired until they are at least one year old, although one ringed individual was known to have formed a brief, two-month, pair-bond with a female when he was no more than 7-9 months of age. Pair-bonds between Bicoloured Antbirds usually begin when an unmated male starts to feed a newly independent, younger female. Observed patterns of pair formation by this species may be influenced by the skewed sex ratio found on Barro Colorado Island, where males outnumbered females by 1.7 to 1, assuring a surplus of unmated males seeking to establish bonds with young females. It is not known if the sex ratios on Barro Colorado are typical for the species as a whole.

The oldest known wild-breeding antbird was a female Plain Antvireo in Trinidad, which was still nesting eight years after having been ringed as an adult. Otherwise, a ringed adult male Dusky Antbird was recaptured in Panama when it was at least 13 years old; nesting at that age, although considered probable, was not proven.

### Movements

The Thamnophilidae are notably sedentary birds. With few exceptions (see Breeding), all species pair for life, and defend territories throughout the year. The majority of forest-dwelling antbirds are reluctant to cross even small open areas, and, as a result, even narrow roads through forested terrain often sharply delimit territories. Two species, the Rufous-capped and Variable Antshrikes, appear to undertake seasonal movements at the extreme southern edges of their distributions, in Argentina. Some evidence from ringing studies suggests that the Great Antshrike makes similar seasonal shifts in N Argentina, although that species is presumed to be resident throughout the greater part of its range. Otherwise, there is nothing to indicate that antbirds undertake migratory movements.

A few bamboo specialists inhabiting the Atlantic Forest of eastern Brazil may move locally in response to large-scale, episodic die-offs of *Merostachys* bamboo. In Itatiaia National Park, in Rio de Janeiro, Brazil, after one such die-off in 1984, all avian bamboo specialists living at 900-1200 m disappeared, and many did not return until 1990, when the bamboo had regrown suffi-

ciently (see also Status and Conservation). Antbirds that appear to be affected by such die-offs include the White-bearded Antshrike and the Ochre-rumped, Rufous-tailed and Bertoni's Antbirds.

### Relationship with Man

Despite their abundance and ubiquity throughout much of the Neotropics, antbirds have little relationship with man. They are not hunted, nor are they kept as cagebirds, and they are not agricultural pests of fields or orchards. Other than a few conspicuous species, such as the Barred Antshrike and the Black-crested Antshrike, which occupy mostly second-growth and edge habitats and even enter yards and gardens, antbirds remain unknown to the vast majority of people who live within their ranges. On the other hand, indigenous peoples and those who depend on an intimate relationship with the forest are often well aware of the antbirds, particularly those species that follow army ants.

Explorers and naturalists since the time of Alfred Wallace and Henry Bates have taken notice of and been fascinated by the relationships of antbirds to the impressive swarms of army ants. To this day, the two avian phenomena that most enthrall nature-orientated visitors to the Neotropics are the spectacle provided by a bird-attended army-ant swarm, and the dazzling chaos of a large mixed-species foraging flock, both of which are frequently centred upon multiple species of antbird. Thamnophilidae is one of the most species-rich families of Neotropical birds, and many antbird species, through their rarity and/or elusive habits, present real challenges to would-be observers. As such, they are frequently among the species most sought after by travelling birdwatchers, and are thus indirectly helping to fuel the burgeoning industry of ecotourism throughout much of Central and South America.

As objects of scientific inquiry, antbirds have provided important examples for man's still evolving theories of biogeography, adaptive radiation and speciation. They have been central to investigations into ant-following by birds, the cohesion and structure of mixed-species flocks, and resource-partitioning, as well as research into the unique contributions of river islands, bamboo and white-sand habitats to tropical avian diversity.

The **Chestnut-crested Antbird** is a restricted-range species present in the Orinoco-Negro White-sand Forests EBA.

Although this taxon was virtually unknown until the mid-1990s, several recent records have greatly extended its known range in Brazil. Despite the fact that it is considered highly sensitive to human disturbance, this species is probably secure meantime, mainly because forests within its range are under little development pressure. Importantly, it has been found in Jaú National Park, Brazil, within whose vast area it currently receives protection.

VIREO]

Over recent decades, the Atlantic Forest of south-east Brazil has suffered severe habitat loss through urbanization, logging and agriculture. As a result of these activities, a dramatic decline must have taken place in the populations of endemic bird species. One of these, the **Spot-breasted Antvireo**, is considered Near-threatened, failing to meet the criteria for fully threatened status because it remains common in foothill forests. At these higher altitudes, habitat is under slightly less pressure, and much of it is protected within reserves.

[*Dysithamnus stictothorax*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: J. S. Dunning/VIREO]

Thamnophilids have also been a major element for scientists studying the importance of vocalizations and behaviour in determining species relationships and reconstructing phylogenies, the effects of logging and forest fragmentation on vertebrate populations, and a wide range of other topics.

For all of this, antbirds remain important to man primarily for aesthetic reasons. As indicators of unspoilt forest, as phantom voices emanating from behind dense curtains of tropical greenery, as creatures that can be both frustratingly elusive and remarkably confiding, and as reminders that there are still many mysteries of nature that we have yet to understand, the antbirds, as much as any other group of birds, evoke and symbolize the most bird-rich forests on the planet for those fortunate enough to have experienced them.

### Status and Conservation

Antbirds are too small to be hunted, and, as mostly drably coloured insectivores with relatively simple songs, they are not targeted for commercial exploitation as cagebirds. Rather, the primary conservation threat for virtually all thamnophilids is habitat destruction. Most antbirds are relatively common within their ranges. The lowland evergreen forest which constitutes the primary habitat for most antbirds is still extensive in much of Amazonia and, despite ongoing clearance, remains one of the least threatened biomes. Nevertheless, rapid deforestation proceeds unabated in many regions, and, if current trends continue, future threats will materialize where none currently exists. The effects on forest-inhabiting birds of clear-cutting and subsequent conversion to cattle pasture and large-scale agriculture are obvious. Most antbirds are averse to crossing roads, rivers and other small discontinuities in otherwise continuous forest. They shun the light and the edge, sticking mainly to the dense cover of the interior. Wholesale forest destruction leaves such birds with no viable options. Less obvious, but worthy of attention, are the effects of forest fragmentation and selective logging, which have been detailed in several studies.

The Biological Dynamics of Forest Fragments Project (BDFFP), a joint initiative of Brazil's National Institute for Re-

search in Amazonia and the US Smithsonian Institution, has generated many data on the effects of forest fragmentation on forest birds, including many antbird species. The BDFFP sites are located north of Manaus, in the heart of Amazonian Brazil. Implemented in 1979, the project has studied the effects of forest fragmentation by creating forest isolates of different sizes, such as 100 ha, 10 ha and 1 ha, which, over time, were surrounded by different-aged stands of second growth ranging from open pasture to tall *Cecropia* woodland. The project is unique in that solid baseline data are available from the sites before isolation from continuous forest took place. In a study of the effects of fragmentation on understory birds, Stouffer and S. H. Borges showed that obligate mixed-flock species and terrestrial insectivores were among those worst affected. The Dusky-throated Antshrike, the Brown-bellied Antwren and the Long-winged Antwren, three mixed-flock core species common in continuous forest and 100-ha fragments, were never mist-netted in 1-ha fragments. Two nuclear species, the Cinereous and the Dusky-throated Antshrikes, and a core species, the Brown-bellied Antwren, ranked seventh, eighth and ninth, respectively, among the ten most commonly mist-netted species in continuous forest, but these did not rank in the top ten in isolates of 100 ha or 10 ha. All of these flock regulars were nearly absent except in 100-ha fragments or in continuous forest. Rufous-bellied Antwrens appeared to be restricted to continuous forest, and did not persist in fragments of any size. Scale-backed Antbirds still utilized 10-ha fragments, but were much more common in continuous forest and 100-ha fragments. Populations of terrestrial-foraging insectivores were also strongly reduced by forest fragmentation, sometimes to the point of local extinction. This was the case for furnariid leaf-tossers (*Sclerurus*), formicariid ground-antbirds and gnateaters (*Conopophagidae*), as well as for the thamnophilid Ferruginous-backed Antbird. Interestingly, data from the same forest fragments showed that most groups of leaf-litter arthropods were more abundant along edges and in smaller fragments than in the interior of large fragments, so that the disappearance of terrestrial-foraging birds from forest fragments did not appear to be related to a reduction in prey. The obligate ant-following White-plumed Antbird and Rufous-throated Antbird ranked, respectively, first and fourth among the ten most commonly mist-netted species in continuous forest, and

A remarkable community of *Drymophila* antbirds is found in the Atlantic Forest. In a small area of south-east Brazil, for example, six species can be found at incremental altitudes: the Scaled (D. squamata) and Dusky-tailed Antbirds (D. malura) lower down; the Ferruginous (D. ferruginea) and Ochre-rumped Antbirds (D. ochropyga) at mid-elevations; and Berton's (D. rubricollis) and the Near-threatened **Rufous-tailed Antbird** at high elevations. In a narrow altitudinal band between 1150 m and 1300 m the latter four species sometimes share the same bamboo thickets.

[*Drymophila genei*, Itatiaia National Park, Rio de Janeiro, Brazil. Photo: Edson Endrigo]

third and sixth in the 100-ha fragments, but were nearly absent from plots of 10 ha and 1 ha. These two species did move through tall *Cecropia*-dominated second growth, which was rarely used by mixed-flock antbirds. The White-flanked Antwren, a species which commonly joins mixed-species flocks but is not a core species, declined less strongly in the smaller fragments. The Warbling Antbird, the Black-headed Antbird and the Black-throated Antbird, all light-gap and edge inhabitants, were the only thamnophilids that were more common in forest fragments and mature second growth than in continuous forest.

Intensified nest predation has been demonstrated to be an important factor in the decline of birds breeding in fragmented-forest landscapes, both tropical and temperate, with rates of nest loss calculated to be inversely proportional to the size of the forest fragments. Intensified nest predation is thought to result largely from an increase in small and medium-sized predators in forest patches through immigration from surrounding deforested areas, and from a reduction in the populations of bigger carnivores the home ranges of which are larger than the forest fragments. Increased predation pressures have been implicated in the extirpation of numerous bird species from Panama's Barro Colorado Island. When the River Chagres was dammed in 1914 in order to fill the Panama Canal, Gatun Lake was created; forested hilltops and ridges became islands in the lake, isolated from one another and from extensive tracts of "mainland" forest. Barro Colorado, the largest island in Gatun Lake, is well known ornithologically, and has been used as a model for research on insular populations. Of twelve ground-foraging insectivorous bird species that have historically bred on the island, eight are now locally extinct, one of these being the Ocellated Antbird. In addition, populations of Bicoloured Antbirds declined by half during an eleven-year period. Dramatically higher predation rates have been recorded, and experimentally confirmed, on Barro Colorado Island in comparison with nearby unfragmented mainland forest.

In one field experiment, K. E. Sieving tested the hypothesis that interspecific differences in nest design and placement could account for differential avian extinction on Barro Colorado. Using 200 artificial nests, carefully constructed to simulate the design and placement of five model species, which included three thamnophilids, the Chestnut-backed, Spotted and Bicoloured

Antbirds, and with quail (*Coturnix*) eggs simulating the standard two-egg clutches of the models, Sieving demonstrated not only much higher predation pressures on the island compared with the mainland, but also that species-specific nest design and placement were important determinants of differential nest predation. This finding did not, however, directly account for patterns of species extinction. Of the simulated nests of the five model species, those of Spotted Antbirds constantly suffered the highest losses to predators on both island and mainland sites; yet Spotted Antbirds have maintained their population levels on Barro Colorado, whereas the Streak-chested Antpitta (*Hylopezus perspicillatus*), the simulated nests of which suffered the least predation, disappeared from the island in 1971 following a period of steady decline.

Sieving's results suggested that nest-design and nest-placement strategies may determine the capacity for clutch replacement, so that species which experience less predation pressure under natural conditions do not have the behavioural and physiological capability for rapid re-nesting in response to predation. When relegated to forest fragments with much more intense predation pressure, populations of such birds may be unable to produce replacement clutches fast enough to keep up. Conversely, such species as the Spotted Antbird, with a nest design and placement that subjects them to constantly high predation under natural conditions, have the capacity for rapid re-nesting, and, thus, a higher tolerance of inflated insular predation pressure. Indeed, Willis estimated that pairs of Spotted Antbirds living on Barro Colorado Island were re-nesting up to ten or twelve times per year before producing a single brood of fledged young. Species such as the Streak-chested Antpitta, the Ocellated Antbird and, seemingly, the Bicoloured Antbird are unable to match the predators clutch for clutch, and eventually become extinct within the fragment. Besides the evolutionary implications of this particular example, the conservation lessons from Barro Colorado give cause for concern for the future of species living in fragmented landscapes. Among antbirds, the prospects are particularly dire for species having current populations already confined to a handful of small, isolated reserves, where, presumably, the same sorts of inflated predation pressure are at work.

The **Ochre-rumped Antbird** has specialized habitat requirements within a tiny range. It lives in dense stands of bamboo and vine-tangles, usually high in the mountains of south-east Brazil, but locally also in the adjacent lowlands. Although it is probably adequately protected in several parks and reserves, episodic large-scale die-offs of bamboo may result in periodical fluctuations in local populations of this and other bamboo specialists, and their status should be monitored carefully. This species, too, is listed as *Near-threatened*.

[*Drymophila ochropyga*,  
São Lourenço da Serra,  
São Paulo, Brazil.  
Photo: Edson Endrigo]

Clear-cutting and forest fragmentation are only the most obvious threats to forest ecosystems. Selective logging is an increasingly common timber-extraction process that has been shown to have an impact on populations of many forest birds, particularly antbirds. A. D. Johns, in a study of the effects of logging on forest bird communities in Pará, Brazil, found that certain groups of species could be taken as indicators of a stable avifauna, reflecting an undisturbed or late-stage successional habitat, and gave as an example a high species richness of terrestrial antbirds. The most important trends that he detected were a decrease in the abundance of terrestrial insectivores and a decrease in bark-gleaning and foliage-gleaning insectivores in proportion to the degree of disturbance by logging. In his study, the frequency of observation of antbirds of the families Thamnophilidae and Formicariidae dropped from 17.9% of the sample in unlogged forest to 13.5% in logged forest and to 0.9% in *capoeira* (second growth). Of 21 thamnophilids, 17 were found to decrease in logged forest compared with unlogged forest, whereas only four, the Fasciated and White-shouldered Antshrikes and the Black-faced and Scale-backed Antbirds, were found to increase. The particular sensitivity of terrestrial and understory species to logging has been demonstrated in multiple studies. The micro-habitat conditions of low light and high humidity in the understory are greatly affected by logging, whereas canopy conditions remain relatively less altered.

D. Mason studied the effects of selective logging on understory bird populations in the Imataca Forest Reserve of south-eastern Venezuela. His was the first study to document the effects of two tropical silvicultural treatments, one of these being so-called "enrichment strips" and the other vine-cutting. Where forest management is approached as an ongoing process, rather than as a one-time extraction, silvicultural treatments may be applied to increase the volume of commercially harvestable wood. Enrichment strips are cleared and then planted with nursery-grown saplings of commercial, and often non-native, tree species. In some locations, these strips are cleared with bulldozers, which scrape the topsoil and inhibit natural regeneration. Trees felled to create the strips are pushed into the adjacent forest, damaging other trees. The other treatment applied to some of the logged forests was the cutting of all woody vines at ground level; vine removal has been shown to increase tree growth rates and to re-

duce the incidence of stem deformity. Mason found that understory bird assemblages were strongly affected by most forestry practices. Bird assemblages in selectively logged forest were significantly different from those in primary forest, and the changes were even greater where enrichment strips were created. By contrast, bird assemblages where vines were cut were similar to those of unlogged forest. Most understory species were insectivores, and the majority of these declined in abundance following logging. The most diverse family of understory birds was Thamnophilidae, 20 species of which occurred in unlogged forest. Four of these, the Northern Slaty Antshrike, the White-flanked Antwren and the Dusky and White-browed Antbirds, increased in abundance following logging; the numbers of two others remained the same, while 14 species declined. Three of the species that declined were not recorded in logged forest; these were the Black-throated Antshrike, the Long-winged Antwren and the Spot-winged Antbird. Even more dramatic changes occurred in logged forest with enrichment strips, where six primary-forest species were not recorded; these were the previous three, along with the Brown-bellied Antwren, the Grey Antwren and the Wing-banded Antbird. Two obligate army-ant followers regularly recorded in the area, the White-plumed Antbird and the Rufous-throated Antbird, were only slightly less common in logged forest, but they were significantly less common where enrichment strips were created.

Mason's study also provided some clues as to the proximate causes of change in species abundance in response to the various logging treatments. Because his study area included forests that had been logged for years as well as others that had only recently been logged for the first time, Mason was able to look at temporal responses of the birds to the logging. Although the microclimate changes are likely to take place immediately after tree removal, many of the effects on the bird communities did not develop until years after harvesting. Four months after logging, the understory structure and its avifauna were similar to those of primary forest, even though the canopy was much more open. Five to six years after logging, the understory vegetation was twice as dense as that of primary forest, and the bird assemblages were significantly different. Of the measured factors, understory forest structure correlated best with changes in bird communities. Many of the understory insectivores, including antbirds,

A Near-threatened  
thamnophilid is the  
**Black-tailed Antbird.**

Not only is it a várzea specialist, but it is patchily distributed and apparently scarce in a small range, chiefly in the drainages of the Marañón, Ucayali and upper Amazon Rivers of northern Peru. Although there is no immediate threat from habitat loss in the region, the flooded-forest ecosystem is vulnerable to deforestation owing to its accessibility along watercourses.

More survey work is required to locate viable populations, which should then be protected within appropriately sited várzea reserves.

[*Myrmoborus melanurus*,  
Callarú River,

Photo: J. S. Dunning/  
VIREO]

are foraging specialists, and selective logging may reduce the amount of foraging habitat for these birds, many of which require a more open understorey in which to seek food.

Another study, by J. M. Thiollay, investigated the effects of selective logging on avian species diversity in lowland forests in French Guiana. Thiollay found that, in the understorey of mature stands, the mostly terrestrial species, including ant-followers, were among the species most affected, closely followed by members of mixed flocks and solitary insectivores. Each of these guilds decreased after logging by over 50%. Among the most affected species, obligate army-ant followers, in this case the White-plumed and Rufous-throated Antbirds, eventually disappeared from the later stages of logged forest. The dominant small insectivores of the understorey, the usual members of mixed-species flocks, were among the most numerically depressed species. These included the *Thamnomanes* antshrikes and the *Myrmotherula* antwrens. Consequently, the understorey mixed-species flocks themselves became rare in logged forest. A few species increased after logging. Among antbirds, these included the Northern Slaty Antshrike, the Black-headed Antbird and the Black-throated Antbird, all of which are more typical of forest edge, light-gaps and secondary woodland. The species that disappeared after logging are typical of primary forest, and are usually rare or absent from other habitats, which makes them of special concern when designing conservation strategies.

Of the 209 species of thamnophilid antbirds, 25, or 12%, are currently considered by BirdLife International to be globally threatened. Eleven of these are categorized as Vulnerable and ten as Endangered, and the status of four species is considered Critical. An additional nine species are considered Near-threatened. Moreover, 59 members of the family qualify as "restricted-range species", each having a global range encompassing less than 50,000 km<sup>2</sup>.

Some general trends are evident among these species. Most have very restricted ranges, limited by habitat or geography, and all are declining in numbers. Of the total of 34 threatened or near-threatened thamnophilids, as many as 21 are found nowhere outside Brazil. These are the Rondonia Bushbird, the Plumbeous Antvireo, the Alagoas, Klages's, Rio de Janeiro, Salvadori's, Unicoloured and Band-tailed Antwrens, the Pectoral and Bahia Antwrens, the Marsh Antwren, the Narrow-billed, Restinga and

Black-hooded Antwrens, the Orange-bellied Antwren, the Rufous-tailed and Ochre-rumped Antbirds, the Rio de Janeiro Antbird, the Fringe-backed Fire-eye, the Slender Antbird and the Scalloped Antbird. A further three species, the White-bearded Antshrike, the Spot-breasted Antvireo and the Rio Branco Antbird, are near-endemics of Brazil. Of these 24 Brazilian antbirds, all but three are confined to the Atlantic Forest, to the *caatinga* and the deciduous forests of the north-east, or to other restricted habitats in the narrow coastal strip. An estimated 80-85% of the Atlantic Forest that was present in the sixteenth century, when

**The Narrow-billed  
Antwren** is considered  
Vulnerable to extinction.  
It is found in mata-de-cipó  
(or "liana forest"), a type of  
dry forest characterized  
by low-stature trees, vine  
tangles and terrestrial  
bromeliads. Wherever  
mata-de-cipó is left  
standing, this species is  
usually fairly common, and  
it would not be threatened  
were it not for the  
devastating rate at which  
such habitat is being  
destroyed. There are still  
no protected areas within  
its range, a situation that  
desperately needs  
to be rectified.

Europeans arrived, had been destroyed by the 1970s. What was historically a largely intact forest covering more than 1 million km<sup>2</sup> is now dominated by several of the biggest centres of human population on the continent. This history of human settlement and environmental devastation has left the Atlantic Forest region by far the most endangered of all biogeographical regions in the Neotropics. The Atlantic Forest region harbours the third largest concentration of endemic birds in the Neotropics, roughly 200 species. Thirty-one of these are thamnophilid antbirds, over half of which, 18, are currently threatened or near-threatened. A number of the remaining ones can be considered to be at some level of risk.

Most of the threatened antbirds of eastern Brazil are forest species. For many of these, a string of parks and reserves stretching from southern Bahia to Rio Grande do Sul, and south inland into southern Paraguay and Argentina, provides some measure of protection. Many of these reserves, however, are small and isolated, rendering their bird populations vulnerable to edge and island or peninsula effects, which include increased predation, lack of immigration, reduced gene flow and increased inbreeding depression. Furthermore, most of the existing parks, particularly the larger ones, in the Atlantic Forest protect montane habitats, whereas the lowland forests, to which more endemic species are restricted, are only minimally protected. The most endangered species are those restricted to lowland-forest remnants. Of these, the Alagoas Antwren, the Rio de Janeiro Antwren and the Fringe-backed Fire-eye have been given the conservation status of Critical. The Alagoas Antwren is known from a single fragmented patch of remnant ridgetop forest at Murici, in the state of Alagoas. The forest at this site has been reduced from 70 km<sup>2</sup> in the early 1970s to less than 30 km<sup>2</sup> in 2000. This forest and scattered similar patches that may be found to harbour the species are surrounded by a virtual sea of sugar-cane plantations. Although the Murici forest has recently been declared a protected area, it remains privately owned, and selective extraction of timber was going on as recently as January 2002. Furthermore, fires spreading from adjacent plantations are constantly eroding the boundaries of the forest. Populations of the Alagoas Antwren are thought to number fewer than 1000 individuals, and are assumed to be declining.

The Rio de Janeiro Antwren is known from a single specimen mist-netted in a patch of secondary forest in central Rio de Janeiro state in 1982. Subsequent to its discovery, the species went unrecorded for more than a decade. Since 1994, there have been regular reports from the Guapi Açu Ecological Reserve, in

the foothills of the Serra dos Órgãos, but some controversy remains as to whether these pertain to the Rio de Janeiro Antwren or to a local variant of the race *luctuosa* of the White-flanked Antwren. Regardless of the identification of the Guapi Açu antwrens, it is clear that, given the near-total destruction of lowland forest on the coastal plain below the Serra dos Órgãos, and the failure to locate additional populations despite much effort, the Rio de Janeiro Antwren must, at best, occupy a tiny range and have a very small population.

The Fringe-backed Fire-eye is known from a highly restricted area in coastal Bahia and southern Sergipe. Many sites at which it was judged common in the 1970s either have been deforested or no longer harbour fire-eyes. Although this species, unlike most forest antbirds, is capable of persisting in patches of second-growth woodland, it is clearly declining throughout its small range, and extant population reservoirs are highly fragmented and isolated from one another. The total population is estimated at fewer than 1000 birds and declining.

For each of these three Critically threatened antbirds, immediate action is needed in order effectively to protect known populations. In addition, surveys of surrounding areas, aimed at locating and protecting additional sites where the birds may occur, are an urgent priority.

The White-bearded Antshrike presents a special case. It occupies lowland and foothill Atlantic Forest from the state of Rio de Janeiro, in Brazil, south-westwards inland to north-east Argentina. Within this range, suitable habitat is highly fragmented, a situation that is likewise facing all other Atlantic Forest endemics. The problem of habitat fragmentation for the antshrike is exacerbated by its apparent dependence on extensive stands of large-leaved bamboos, probably in particular those of the genus *Merostachys*, which are characteristic of the montane Atlantic Forest. These bamboos undergo periodic local die-offs, forcing bamboo specialists to move elsewhere. After one such event in Itatiaia National Park, in 1984, when the 12-m-tall *Merostachys* died en masse, all such specialists within an elevational range of 900-1200 m disappeared, and many did not return until 1990, by which time the bamboo had regrown to heights of 5 m or more. These episodic die-offs, and the lengthy regeneration periods that follow, create large spatial and temporal discontinuities in the availability of suitable habitat for such birds as the White-bearded Antshrike. As a buffer against cyclic perturbations of their environment, specialists of this kind probably require areas of contiguous habitat that are larger than average.

The **White-bearded Antshrike** is rare throughout its small Atlantic Forest range. It is made susceptible to extinction by its reliance on patches of bamboo, particularly of the genus *Merostachys*, which is known to undergo episodic local die-offs. These die-offs result in large geographical and temporal discontinuities in the availability of suitable habitat, a situation exacerbated by rampant forest fragmentation. The species requires large reserves with extensive stands of bamboo at a variety of elevations.

[*Biatas nigropectus*, Cruce Caballero National Park, Misiones, Argentina. Photo: José & Adriana Calo]

Thirty-four species of antbird are considered threatened or Near-threatened with extinction. Of these, 21 are endemic to Brazil. One such species is the **Pectoral Antwren**, which occupies a fragmented range in the country's dry north-east. It lives in gallery forest, deciduous woodland and tall caatinga, habitats that are rapidly being cleared for firewood and charcoal, and to make way for agriculture. This process is reducing its population to dangerously low levels. It only receives protection at one site, the Itabaiana Reserve in Sergipe; other reserves are required.

[*Herpsilochmus pectoralis*, Jeremoabo, Bahia, Brazil. Photo: Kevin Zimmer]

Not all of the threatened antbirds of eastern Brazil are Atlantic Forest endemics. The Slender Antbird is restricted to *mata-de-cipó* forests (see Habitat) in a small area of eastern Bahia, while the Narrow-billed Antwren occurs primarily in the same habitat, but with a slightly more extensive range that includes northern Minas Gerais. Both species are locally fairly common in appropriate habitat, particularly around Boa Nova and Jequié, in Bahia, but the dry forests of this region are being rapidly cleared for cattle pastures and coffee plantations, and much of the remaining *mata-de-cipó* has been degraded by removal of wood for fence posts, firewood and charcoal production, or by livestock grazing the understorey. Numerous calls have been made for the creation of a *mata-de-cipó* reserve near Jequié or Boa Nova, but to date this unique habitat remains unprotected.

Of the Amazonian and Guianan antbirds for which lowland evergreen forest is the primary habitat, only six are currently listed as threatened or near-threatened. These are the Cocha Antshrike, the Rondonia Bushbird, Klages's Antwren, the Ancient Antwren, the Rio Branco Antbird and the Black-tailed Antbird. The Allpahuayo Antbird, not described until 2001, must also be added to this list. It is known only from Loreto, in north Peru, where it is recorded from the drainage of the Río Nanay west to the left bank of the Río Tigre. It is an extreme habitat specialist, occurring primarily in a very dense and stunted *terra firme* forest of a type known locally as *varillal*, and also, to a lesser extent, in a nutrient-poor habitat known as *irapayal* (see Habitat). The Allpahuayo Antbird seems to be restricted to these two habitats, as evidenced by its apparent absence from intensively investigated areas between Iquitos and the Río Napo which lack them, and which lie immediately east of the known range. Unless it is discovered elsewhere, this antbird must rival the Marsh Antwren for the dubious distinction of occupying one of the most specialized habitat niches within the smallest geographical range of any thamnophilid. The habitats in which the Allpahuayo Antbird is found are locally distributed, and are subject to intense human exploitation in a region of rapid population expansion. Both *varillal* and *irapayal* are heavily exploited to provide poles and thatch for building materials to support increasing human settlement in the Iquitos region. A vital conservation action was the recent establishment by the Peruvian government of the Zona Reservada Allpahuayo-Mishana. This new reserve encompasses much of the known range of the Allpahuayo Antbird, and holds many other white-sand specialists, such as the near-threatened Ancient Antwren, the conser-

vation status of which is dependent on many of the same factors as affect the Allpahuayo Antbird.

Known solely from a single female specimen and two sightings of males, all in 1986, at Cachoeira Nazaré, on the west bank of the Río Jiparaná in Rondônia, Brazil, the Rondonia Bushbird is an enigmatic species. Five experienced observers spent 1400 hours and amassed 1450 net-days at the type locality over a five-month period, with only the single mist-net capture and two sightings as evidence of the bird's existence. An additional 250 hours and 375 net-days at a similar locality 70 km distant, but not separated by any apparent barrier, produced no further sightings. There have been no confirmed records of the species since 1986, and its conservation status is Critical. Next to nothing is known of the natural history of the Rondonia Bushbird, but nothing about the type locality, nor the circum-

Another threatened antbird endemic to the Atlantic Forest of east Brazil is **Salvadori's Antwren**, currently classed as **Vulnerable**. It is restricted to lowland forests in the coastal stretch from southern Bahia to northern Santa Catarina. The huge human population pressure means that most forest in this zone is under threat, especially the lowland forest, which is the most accessible and attractive for development schemes. In this sense, the extensive Serra do Mar State Park and other reserves have a most important part to play.

[*Myrmotherula minor*, Ubatuba, São Paulo, Brazil.

Photo: Edson Endrigo]

The **Bicoloured Antvireo** is currently classed as **Vulnerable**. This is largely because its mid-elevation habitat in the Andes of Colombia and northern Ecuador has been severely affected by logging, conversion to livestock farming and clearance for crops, principally coffee and naranjilla. The best known population is found on the Guacamayos Ridge, and nearby at Volcán Sumaco, Ecuador. Large areas of pristine forest survive in this region, some of it nominally protected within Sumaco-Galeras National Park.

[*Dysithamnus occidentalis punctitectus*, Guacamayos Ridge, Ecuador.  
Photo: Joe Fuhrman/VIREO]

For over six decades the only thing masking the **White-masked Antbird** was mystery. Proof of its existence rested on a single specimen, collected in 1937 in one of the remotest corners of Amazonia. Due to shifting borders and an ambiguity regarding place names, it was never entirely certain whether the type locality lay in Peru or Ecuador. In the end, the species went so long unobserved, despite several intensive searches, that its taxonomic status was called into question. It began to be assumed that it must be a hybrid between the White-plumed Antbird (*Pithys albifrons*) and some other thamnophilid whose identity was difficult to guess. On account of these views the taxon was eliminated from recent assessments of threat status. Only in 2000 was the enigma finally unmasked. The species was found to be a "professional" ant-follower, and relatively common in white-sand forests in far northern Peru. In view of its highly restricted range, its habitat preferences and its ecology, its status must be considered of critical concern. It would receive important protection within Santiago Comaina Reserved Zone, although it is discouraging to note that local opposition to this reserve has been reported.

[*Pithys castanea*,  
Santiago Comaina  
Reserved Zone,  
Loreto, Peru.  
Photo: José Álvarez Alonso]

The **Band-tailed Antwren** is considered Endangered, principally because it is confined to humid Atlantic Forest in the extreme lowlands of south-east Brazil.

This forest type is precisely the habitat that is most vulnerable to clearance for urbanization, agricultural expansion, settlement and road-building. The species survives in a few reserves, such as those at Sooretama and Monte Pascoal, and it is therefore vital that these sites receive strict and long-term protection.

[*Myrmotherula urosticta*, Ituberá, Bahia, Brazil.  
Photo: Pedro Lima]

stances of the capture and two sightings, suggests that it is confined to a specialized habitat in the way that the Allpahuayo Antbird and the Ancient Antwren are. Instead, the bushbird seems to be a genuinely rare, low-density species. In the 1980s, Rondônia had the fastest rate of deforestation in Brazil, a result of government programmes that encouraged human settlement of Amazonian frontier regions. By 1983, 5% of the forest in Rondônia had been destroyed, almost all of it since 1970, and completion and paving of the highway joining Porto Velho to south-east Brazil accelerated human settlement and forest clearance. Although the initial wave of settlement and road-building has waned, commercial logging operations in the region have increased, and an estimated 4000 km<sup>2</sup> of forest are being cleared each year in Rondônia. Even the type locality of the bushbird is the site of an ongoing hydro-electric project. Surveys aimed at rediscovering the bushbird and identifying its principal ecological requirements, followed by effective protection of key sites, are clearly required.

Although the Cocha Antshrike, following its initial discovery in 1926, was not recorded again for much of the rest of that century, it was finally rediscovered, in 1991, at Imuyacocha, very near the type locality, in the Ecuadorian province of Napo. It has subsequently been found to be fairly common along black-water drainages in the region, and, although the species has yet to be found outside Ecuador, it seems likely that it could occur in adjacent Colombia and Peru. While oil exploration and extraction, and the inevitable deforestation that accompanies these activities, present possible threats to the lowland avifauna of eastern Ecuador, the Cocha Antshrike is probably at little near-term risk, given the lack of suitability of its habitat for agricultural development. Similarly, Klages's Antwren was long known only from specimens, these collected near Santarém, near the mouth of the Rio Tapajós, in Brazil. Around 1990, it was rediscovered on river islands in the Anavilhanas Archipelago in the Rio Negro, north-west of Manaus. Surveys of the archipelago, which is formally protected, have shown the antwren to be locally common, as has recent work on river islands near the type locality. These are two cases where additional survey work could lead to a reassessment and upgrading of the conservation status of species that were unknown in life prior to 1990.

The Black-tailed Antbird, like the previous two species, is currently listed as Near-threatened. Once more is learnt of its specific micro-habitat requirements, however, it, too, may prove to be more common and less range-restricted than thought. To date, it is known from relatively few locations in a small portion of north-east Peru and extreme western Brazil, but the flooded-forest habitats that it occupies are extensive, relatively

intact, and under little short-term threat of large-scale development. Conversely, surveys have delimited the range of the Rio Branco Antbird and have led to an understanding of its habitat requirements. This species, however, is found only along a small section of the Rio Branco and some of its tributaries in Roraima, northernmost Brazil, and in extreme southern Guyana. It inhabits dense thickets in gallery-forest understorey, within 0.5 km of the rivers, and a somewhat wider range of habitats on select river islands. Thus, its distribution is narrow and linear, and the estimated extent of suitable habitat is 250 km<sup>2</sup> or less. Its range does not include any formally protected areas, and its habitat has been degraded by widespread burning both on the riverbank mainland and on the river islands. For these reasons, the Rio Branco Antbird is considered Vulnerable, despite the fact that it is locally common.

The **Restinga Antwren** takes its name from the sandy seaside copses in which it lives. Its ecology is specialized, its range tiny, and thus its overall population must be very small. Unfortunately, restinga woodland in the state of Rio de Janeiro is under pressure from industrial activity and clearance for beach-front housing. The establishment of a new and functional restinga reserve would be an important step towards ensuring the survival of this attractive antbird.

[*Formicivora littoralis*, Cabo Frio, Rio de Janeiro, Brazil.  
Photo: Luiz Pedreira Gonzaga]

Of the two known races of the **Scalloped Antbird**, the nominate is the less common. It ranges from Espírito Santo north to southern Bahia, where it is now restricted to its few last strongholds. The northern race *soror* lives at higher densities, where it occurs, but unfortunately the area of forest involved is tiny. Although this is only one of many species that would benefit from the protection of the last forest fragments in Alagoas state, efforts to secure this protection have so far failed.

With regard to the status of various thamnophilids, one of the great remaining mysteries was resolved with the recent rediscovery of the White-masked Antbird. The species was previously known from a single specimen collected in 1937, somewhere in the lower Río Pastaza region of eastern Ecuador and northern Peru. It remained unrecorded for more than 60 years, despite concerted efforts to find it along the upper reaches of the river in both countries. Even the type locality, "Andoas", has never been located with certainty. Subsequent authors have suggested that the type specimen was, in fact, a hybrid between the White-plumed Antbird and some other antbird species, rather than a distinct species. Then, in July 2001, a team from Louisiana State University's Museum of Natural Science, in the United States, working some 45 km from the Río Pastaza, in north-western Loreto, not only rediscovered the White-masked Antbird, but found it to be locally fairly common in that part of Peru. The bird was found in an isolated patch of sandy-soil *varillal* woodland, but was absent from surrounding forest growing on richer soils. Like several other long-lost or recently discovered antbirds, the White-masked Antbird is now believed to be largely restricted to sandy-soil habitats. More surveys are needed in order to establish the extent of suitable *varillal* habitat in the region, to confirm the geographical boundaries of the antbird's range, and to determine whether White-masked Antbirds are uniformly distributed through the appropriate habitat. Until then, the true conservation status of this species, officially listed as Data-deficient, remains in doubt. It does, however, provide yet another dramatic example of how white-sand habitats in Amazonia have been under-investigated, and of how underlying soil mosaics can influence bird distribution.

All but one of the remaining threatened or near-threatened antbirds occupy small ranges in the foothills of the Andean countries. These range-restricted Andean endemics are at particular risk, in part because they, like most Andean species, have relatively narrow elevational range limits. The Bicoloured Antvireo occurs between 900 m and 2200 m in a small corner of Colombia and Ecuador, the Yungas Antwren from 600 m to 1400 m in the east Andean foothills of Bolivia, the Ash-throated Antwren at 1350-1450 m at just two localities in north-central Peru, and the Yellow-rumped Antwren from 1100 m to 1700 m in northern Bolivia and southern Peru. The first two of those are listed as Vulnerable and the last two as Endangered. Restriction to narrow elevational zones means that the ranges of these birds are not only tiny but also linear, and the clearing of even a few hun-

dred metres of forest can have the effect of fragmenting their ranges. This is an especially important consideration given that the very elevations occupied by these species are also prime areas for agricultural exploitation, particularly for growing coca, coffee, tea and naranjilla, as well as for logging and human settlement. The Grey-headed Antbird, a Vulnerable endemic of the Tumbes region of south-west Ecuador and north-west Peru, is found at 600-2900 m, thus across broader elevational limits than the aforementioned species, but its range has become highly fragmented by habitat destruction. From 1958 to 1988, the rate of deforestation below 900 m in western Ecuador was calculated to be 57% per decade, with the result that the Grey-headed Antbird is now confined to a few isolated areas, mostly at the upper end

The **Slender Antbird**, sole occupant of its genus, is **Endangered**. It is restricted to *mata-de-cipó*, a vegetation characterized by tangled growths of lianas and patches of terrestrial *Aechmea bromeliads*. This habitat forms a narrow interface between the coastal humid forests of east Brazil, and the interior caatinga woodlands. Slender Antbirds are extreme specialists on *Aechmea bromeliads*, in whose shelter they forage, sing and presumably place their nests. The global population of this interesting bird currently stands at 1000-2500 individuals, and is falling.

[*Rhopornis ardesiacus*,  
Boa Nova, Brazil.  
Photo: Luiz Claudio Marigo]

Although the **Black-hooded Antwren** appears capable of surviving in a variety of humid second-growth habitats, its total range is estimated at only 130 km<sup>2</sup>, and its total global population is thought to number 1000-2500 individuals. Woodlands on the narrow coastal plain to which it is confined continue to be cleared for tourist facilities, beachside housing, pastures and plantations of *Euterpe* palms. It is essential that this type of destruction is curtailed and that appropriate protected areas are established. The species is listed as Critical.

[*Formicivora erythronotos*, Rio de Janeiro, Brazil. Photo: Luiz Claudio Marigo]

of its altitudinal range. Significant population reservoirs still exist in the largely intact forests of the Tumbes Reserved Zone, in Peru, but recent cessation of border hostilities between Peru and Ecuador has had the collateral effect of reducing the Peruvian military presence that previously prevented squatting, wood-cutting, hunting and other extractive activities by people illegally entering the Reserved Zone.

A thamnophilid of particular concern is the Recurve-billed Bushbird, which has been observed at only a few foothill sites in northern Colombia, and in the Sierra de Perijá of extreme north-western Venezuela. The species has not been recorded since 1965, this due no doubt in part to both the secretive nature of bushbirds in general and the fact that few surveys have been attempted because of political instability and guerilla activities in the regions involved. Nonetheless, deforestation for cattle-ranching, logging, gold-mining and agriculture, the last involving particularly coca and associated narcotics production, has been extreme in this region, and the global population of this Endangered bushbird must be very small.

Of the 39 species of antbird that occur in Central America, all but two, the Black-hooded Antshrike and the Streak-crowned Antvireo (*Dysithamnus striaticeps*), have ranges that extend into South America. Many of these species are distributed at least from Costa Rica to the Pacific slope of Ecuador, and some extend much farther. Accordingly, only one thamnophilid from Central America is considered threatened, that being the Speckled Antshrike of Panama and extreme north-western Colombia. This Vulnerable antshrike has a peculiarly fragmented distribution, with known localities separated by intervening areas of intact, seemingly suitable habitat that are apparently unoccupied. It may be another low-density species that was never particularly common, but the combination of a restricted range and ongoing habitat destruction within that range gives cause for alarm. The Black-hooded Antshrike and the Streak-crowned Antvireo occupy comparatively tiny ranges, but they are relatively common in some large Costa Rican parks and reserves that appear to be effectively protected.

A situation that has received very little attention is the almost total devastation of lower Amazonian forest east of the Rio Tocantins in eastern Brazil. The lowland forests of Maranhão and north-east Pará make up what has been termed the Belém or Maranhão Centre of Endemism, and constitute the easternmost extension of the southern Amazonian humid forest. In just a few decades, these forests have been reduced to a pitiful remnant of

their former state. Clear-cutting for commercial logging has been the primary culprit, accompanied by ever-expanding human settlement. The remaining primary forest is small and highly fragmented. In spite of this, the plight of this region has gone nearly unnoticed, chiefly because there are few species endemic in the region. This "species-only" approach to conservation belies the fact that there are numerous distinctive taxa that are endemic, or nearly endemic, in this biogeographical region. Among the antbirds here, taxa which must be considered threatened are the subspecies *incertus* of the White-shouldered Antshrike, the nominate race of the White-backed Fire-eye, and the subspecies *paraensis* of the Black-spotted Bare-eye. Although these taxa, and many others endemic in the region, are currently classified as subspecies of wider-ranging polytypic species, some will no doubt be elevated to full species status once taxonomic analyses incorporating molecular and vocal data are carried out (see Systematics). This serves to illustrate the danger of taxonomies that underestimate species-level biodiversity, the result being that many unique life forms are overlooked when conservation priorities are being set.

## Genus *CYMBILAIMUS* G. R. Gray, 1840

### 1. Fasciated Antshrike

#### *Cymbilaimus lineatus*

**French:** Batara fascié **German:** Zebraameisenwürger **Spanish:** Batará Lineado

**Taxonomy.** *Lanius lineatus* Leach, 1814, Berbice = New Amsterdam, Guyana. Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Previously treated as conspecific with *C. sanctaemariae*, but latter sympatric almost throughout its range. Race *intermedius* appears to be inseparable on plumage from *fasciatus*; in addition, described race *brangeri* appears indistinguishable from and falls within geographical range of latter, and is thus considered untenable. Three subspecies recognized.

#### **Subspecies and Distribution.**

*C. l. fasciatus* Ridgway, 1884 - extreme SE Honduras (El Paraíso), Caribbean slope in Nicaragua and Costa Rica, both slopes in Panama (on Pacific slope locally from Chiriquí to Coelé and in E), W & N Colombia (S in Magdalena Valley to Caldas), NW Venezuela (both Andean slopes E to Mérida and Barinas) and NW Ecuador (Esmeraldas, N Los Ríos).

*C. l. intermedius* Hartert & Goodson, 1917 - S Venezuela (W Bolívar, Amazonas), S Colombia (S from Meta and Guainía), E Ecuador, E Peru, NW & S Amazonian Brazil (E to R Branco and R Negro and, S of R Amazon, E to R Tocantins and S to Acre, Rondônia and Mato Grosso) and NW & extreme E Bolivia (Pando, La Paz, E Santa Cruz).

*C. l. lineatus* (Leach, 1814) - E Venezuela (E Bolívar) E to French Guiana and S to NE Amazonian Brazil (N of R Amazon and E of R Branco and R Negro in Amazonas, Pará and Amapá).

**Descriptive notes.** 17-18 cm; 35-40 g. Heavy bill. Male nominate race has forehead and crown black with a few extremely narrow white bars; remaining plumage narrowly barred black and white; iris red. Distinguished from similar *C. sanctaemariae* by only minimally crested appearance, bars on forehead, more white on tail, red eyes. Female has rufous crown, rest of plumage narrowly barred dark brown and pale yellowish-brown, tail barred pale buff. Subadult male has broader white bars across crown and wider white barring. Race *fasciatus* has strongly barred forehead contrasting with solid black crown, female with cinnamon

tailbars; *intermedius* has same crown pattern as previous, but differs in having light bars on tail relatively wider (but individual and age variation in both races creates overlap in this character). **VOICE.** Loudsong an evenly paced series of 3-10 plaintive, lazily delivered whistles, notes longer than spaces, middle notes sometimes longer and at slightly higher pitch. Calls include rattle-like chatter and plaintive downsliding whistle, often intermixed in series.

**Habitat.** Vine tangles and dense mid-storey canopy of lowland evergreen forest, both at edge and in interior. More often found in second growth and thickets, outside dense forest, in Central America than in Amazonia. Usually below 800 m, rarely to 1600 m; at slightly lower elevations than *C. sanctaemariae* where ranges overlap in Andean foothills.

**Food and Feeding.** Variety of mostly large insects, including Orthoptera (grasshoppers, crickets, katydids), beetles (Curculionidae), hemipteran bugs (Pentatomidae), homopterans, lepidopteran larvae, and others; also spiders; also small lizards, such as anoles, and small frogs; rarely, small fruits. Individuals or pair-members move sluggishly through vegetation by short, heavy hops, pausing sometimes for long periods to scan foliage; prey gleaned by lunging stabs or reaches, or by quick, short sallies. Forages mostly at 5-25 m above ground, particularly in vine tangles and clusters of philodendrons (*Philodendron*) close to trunks, sometimes descending lower at forest edge. Joins mixed-species flocks of insectivores, particularly antwrens and foliage-gleaners (Furnariidae), as these pass through its territory. Similarly, attends army-ant swarms passing through, on such occasions descending to near ground level.

**Breeding.** Apr-Jun in Costa Rica and Jul-Nov in Amazonian Brazil; fledgling being fed in Oct in Surinam and in Sept in French Guiana. Additional nest and egg descriptions from Panama and Colombia. Nest a thin-walled cup of loosely woven dark fibres, attached by rim in horizontal fork, among foliage, 2-10 m above ground. Normal clutch 2 eggs, creamy white, spotted with olivaceous-brown, chocolate-brown, vinaceous-drab and/or pale lilac; incubation by both parents during the day, by female at night, period not known.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Common to uncommon throughout its extensive range, which includes numerous formally protected areas, as well as vast areas of unprotected but still intact suitable habitat, particularly in Amazon Basin and Guianan regions.

**Bibliography.** Angehr & Christian (2000), Blake, J.G. & Loiseleur (2001), Cody (2000), Cohn-Haft *et al.* (1997), Eisenmann (1952), Gyldestolpe (1945a), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Munn & Terborgh (1979), Oniki (1979c), Oniki & Willis (1972, 1982), Parker (2003a), Pierpont & Fitzpatrick (1983), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Salaman, Donegan & Cuervo (2002), Schubart *et al.* (1965), Sick (1993, 1997), Skutch (1972, 1976), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Thiollay (1988a), Thiollay & Julien (1998), Tostain *et al.* (1992), Wetmore (1972), Willis (1984d), Zimmer, J.T. (1932f), Zimmer, K.J. (2003a).

### 2. Bamboo Antshrike

#### *Cymbilaimus sanctaemariae*

**French:** Batara des bambous **Spanish:** Batará de Madre de Dios  
**German:** Bambusameisenwürger

**Taxonomy.** *Cymbilaimus lineatus sanctaemariae* Gyldestolpe, 1941, Victoria, Pando, Bolivia.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Previously treated as conspecific with *C. lineatus*, but occurs sympatrically with that species. Monotypic.

**Distribution.** Locally in SE Peru (Cuzco and Madre de Dios), SW Amazonian Brazil (Acre and Rondônia) and NW Bolivia (Pando and N La Paz).

**Descriptive notes.** 16-17 cm; 28-33 g. Large bill. Male has black forehead and crown, remaining plumage narrowly barred black and white; iris dark brown. Distinguished from similar *C. lineatus* by more crested appearance, no bars on forehead, white on tail confined to rounded spots on sides, different eye colour. Female differs from male in rufous crown, crest tipped black, throat pale buffy white and unbarred, underparts cinnamon-buff with barring limited to sides. **VOICE.** Loudsong a countable series of 4-20 (typically 10-12) short, dry, strident notes, even in frequency, pace and intensity except for initial soft notes. Calls include

soft, downward-inflected whistle, and short rattle that is often introduced by emphatic downward-inflected note.

**Habitat.** A near-obligate bamboo specialist. Occupies upper strata of thickets of *Guadua* bamboo inside humid lowland and foothill forests, to 1200 m. More common in extensive stands of bamboo on sunny slopes with broken canopy of overtopping trees. Also sometimes inhabits dense vine tangles from mid-storey into subcanopy of floodplain-forest, including some that lack bamboo.

**Food and Feeding.** Stomachs of four birds from Peru revealed remains of several beetles (Coleoptera), a 15-mm short-horned grasshopper (Acrididae), a small cockroach (Blattidae), a 30-mm lepidopteran larva, and a 6-mm ant. Forages in pairs, occasionally in loose association with mixed-species flocks of insectivores as they pass through its territory. Forages primarily in crowns of bamboo, in dense masses of fine leaves and branches, c. 8 m above ground, but also in dense foliage and vine tangles in trees surrounding or to c. 20 m above the bamboo; hops along branches deliberately, peering at substrate. Primarily perch-gleans or sallies short distances, less often employing other acrobatic moves, to obtain arthropods from bamboo stems, foliage and vine tangles; occasionally probes clusters of dead leaves.

**Breeding.** Nothing known.

**Movements.** Presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Fairly common in appropriate habitat within its somewhat limited range. Patchy distribution is seemingly based on localized nature of extensive stands of *Guadua* bamboo, which may be spreading with increasing human disturbance in SW Amazonia. Represented in Brazil by apparently disjunct populations in Acre and Rondônia (E of R Madeira), but has not been recorded from extensive *Guadua* stands in the Alta Floresta region of Mato Grosso. Brazilian populations, particularly those in Rondônia, could be at risk as a result of complete deforestation in some areas.

**Bibliography.** Foster *et al.* (1994), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Kratter (1997a), Parker (2003a), Parker *et al.* (1997), Pierpont & Fitzpatrick (1983), Remsen (2003b), Remsen & Parker (1984), Ridgely & Tudor (1994), Rosenberg (2003), Servat (1996), Sick (1993), Stotz *et al.* (1996), Whittaker & Oren (1999), Zimmer (2003a).

## Genus *HYPOEDALEUS* Cabanis & Heine, 1859

### 3. Spot-backed Antshrike

#### *Hypodaleus guttatus*

**French:** Batara moucheté **German:** Perlenmantel-Ameisenwürger **Spanish:** Batará Goteado

**Taxonomy.** *Thamnophilus guttatus* Vieillot, 1816, Rio de Janeiro, Brazil.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Relationships uncertain; historically placed after *Cymbilaimus* because of similarity of bill morphology, and ecology also somewhat similar. Paler N birds (Alagoas S to Espírito Santo) described as race *leucogaster*, but apparently broad zone of intergradation with S populations exists, with both extremes as well as intermediates occurring in São Paulo; racial division considered unwarranted. Monotypic.

**Distribution.** E & SE Brazil (E Alagoas and E Bahia S to extreme E Mato Grosso do Sul, Santa Catarina and N Rio Grande do Sul), E Paraguay (E of R Paraguay; one record on W bank, in SE Alto Paraguay) and extreme NE Argentina (Misiones).

**Descriptive notes.** 20-21 cm. Heavy bill. Male has black upperparts spotted and barred white, brownish-black tail barred white; white below, sides pale grey, lower underparts brownish-yellow, but in N ("leucogaster") underparts almost completely lack brownish-yellow. Female resembles male, but upperpart spots pale buff, brownish-yellow below more extensive (but in N restricted to posterior portions of underparts). **VOICE.** Loudsong a long (e.g. 4 seconds) vibrant trill, building in intensity and frequency before dropping off at end. Calls include long, downward-inflected whistle, shorter, slightly descending churr, and abrupt "chip".

**Habitat.** Vine tangles in canopy and subcanopy of lowland evergreen forest, to 900 m. Confined to wetter sections of forest with dense vegetation.

**Food and Feeding.** Variety of insects, including orthopterans, hemipteran bugs, beetles (Coleoptera) and, particularly, larger larvae of Lepidoptera; also other arthropods such as spiders; also snails;

possibly some small vertebrates such as tree-frogs and lizards. Usually in pairs, sometimes loosely associated with mixed-species flocks, but typically alone. Forages mostly 8-15 m above ground, through dense tangles of vines and epiphytes, progressing sluggishly by heavy hops, pausing sometimes for long periods, scanning nearby leaves and branches, particularly leaves of bromeliads and epiphytic ferns. Prey often gleaned by quick, snatching motions; larger items beaten repeatedly against branches before being consumed. One published record of an individual in Brazil (Boracéia, in São Paulo) following army ants (*Labidus praedator*) for 55 minutes as these moved through a dense treefall zone; it hopped on low logs and in shrubs, peering about; ignored ground prey, but captured eight small prey by gleaning from limbs (four times), and logs (twice), or by short sallies to a trunk 1-3 m up and to a leaf 1 m up.

**Breeding.** Nest undescribed. Eggs white, with irregular lilaceous dots and fine lines, larger blackish spots.

**Movements.** Presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Its range includes several reserves, e.g. Iguaçu National Park, in Argentina, Augusto Ruschi Biological Reserve, Boracéia Forest Reserve and Serra da Bocaina National Park, in Brazil, and Cerro Corá National Park and Mbaracayú Forest Nature Reserve, in Paraguay. Generally rare, however, outside reserves and appears to be sensitive to disturbance. The Serra do Mar may be a Brazilian stronghold. Smaller, isolated populations in the Serra da Ouricana are at risk owing to ongoing deforestation. Although not currently considered threatened, its relatively small range and the highly fragmented nature of remaining Atlantic Forest are causes for concern for this species, which seems to require large territories.

**Bibliography.** Aleixo (1999), dos Anjos (2001a), Christiansen & Pitter (1989), Cory & Hellmayr (1924), Fraga & Narosky (1985), Gonzaga *et al.* (1995), Ihering (1900), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Nehrkorn (1899), Oates & Reid (1903), Pacheco & Whitney (1995), Parker (2003a), de la Peña (1988), Pinto (1932), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1967), Sick (1993), Stotz *et al.* (1996), Whitney (2003a), Willis (1984d), Zimmer (2003a).

Genus *BATARA* Lesson, 1830

4. Giant Antshrike

*Batara cinerea*

**French:** Batara géant

**German:** Riesenameisenwürger

**Spanish:** Batará Gigante

**Taxonomy.** *Thamnophilus* [sic] *cinereus* Vieillot, 1819, Rio de Janeiro, Brazil.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Relationships uncertain; possibly closest to the *Thamnophilus doliatus* complex. Populations in Bolivia, W Paraguay and NW Argentina require study; recent specimens from presumed range of race *argentina* (in E Bolivia lowlands) approach *excubitor* in paleness, and plumage differences between the two may be clinal; also, diagnosable differences may possibly be found between lowland and foothill populations. Three subspecies recognized.

**Subspecies and Distribution.**

*B. c. excubitor* Bond & Meyer de Schauensee, 1940 - C Bolivia (W Santa Cruz).

*B. c. argentina* Shipton, 1918 - E Bolivia (S Santa Cruz, Chuquisaca, Tarija), W Paraguay (Boquerón, Presidente Hayes) and NW Argentina (Jujuy, Salta, N Tucumán).

*B. c. cinerea* (Vieillot, 1819) - SE Brazil (S Espírito Santo and SW São Paulo S to Santa Catarina and N Rio Grande do Sul) and NE Argentina (Misiones).

**Descriptive notes.** 30-34 cm, 148-155 g (*cinerea*); 27-28 cm, 100-110 g (*argentina*). Bill long and heavily hooked, tail very long and broad. Male has forehead, crown and crest black, mantle, wings and tail barred black and white; rest of plumage neutral grey. Female is olive, becoming yellowish on posterior underparts; crest rufous, variably tipped black; mantle, wings and tail barred cinnamon-buff and dark brown. Race *argentina* is smaller than nominate, with fewer bars on wings and tail, female slightly paler above, warmer-coloured below, with less black on crest; *excubitor* is paler than previous, with more restricted dark

markings. **Voice.** Loudsong a short roll (like a police whistle), followed by loud, strident notes of constant frequency, intensity and pace, and ending with soft "chip", total length c. 3 seconds. Calls include long, raspy, downward-inflected snarl, often repeated rapidly, and a short even series of abrupt loud notes.

**Habitat.** Understorey and mid-storey of evergreen forest, from lowlands to 2600 m in the Andes. At lower elevations in Bolivia, Paraguay and Argentina, occupies dense thickets of often thorny bushes surrounded by terrestrial bromeliads in subhumid, often xerophytic, stunted Chaco woodland; in the Andes found in montane forest, especially where dense growth occurs along margins of ravines and streams. In Atlantic Forest region ranges from near sea-level to wet elfin ridgetop forest, almost always with extensive stands of bamboo.

**Food and Feeding.** Large insects, including beetles (Coleoptera), and other arthropods; also snails and slugs; also small vertebrates, including frogs, lizards and small snakes. Reported also to take small mice, nestling birds, and eggs. A male in Brazil (Rio Grande do Sul) was seen to pounce on a large tree-frog (*Hyla*) with body length c. 8 cm, which it skewered with the bill and then bashed several times on the ground, before swallowing. Individuals or pairs forage in dense vegetation 0-15 m above ground (mostly below 5 m), progressing by heavy hops and short, sailing flights, pausing to scan vegetation and the ground for prey; often "squirrels" along horizontal branches or up thick vines. Reaches out, up or down to glean prey from leaf, stem and branch surfaces with a quick stabbing motion of the bill; other items, particularly frogs, lizards and large orthopterans, are frequently flushed from vegetation and pursued to the ground. Does not associate with mixed-species flocks.

**Breeding.** Nests in N Argentina in Oet (Tucumán), Nov (Jujuy) and Dec (Salta), and in Brazil (São Paulo) in Nov. Nest very large, external diameter 18-20 cm, depth 8 cm, an untidily constructed cup of stalks, grasses, *Tillandsia*, leaves and fibres, likened to nest of thrush (*Turdus*), placed 1-5-3 m above ground in a fork or corner between branches in dense vegetation. Normal clutch 2 or 3 eggs, whitish, with crown of darkish marks and other smaller, almost reddish marks around blunt end.

**Movements.** Presumed resident throughout range; in some regions, possibly some local movement following large die-offs of bamboo.

**Status and Conservation.** Not globally threatened. Seemingly healthy populations in several large parks and reserves in Brazil, among them Itatiaia, Serra dos Órgãos, Aparados da Serra and Iguaçu National Parks, as well as in higher elevations of the Serra do Mar; also in NW Argentina, such as Calilegua National Park. Requires relatively large territories; does not survive in small residual forest patches in the Atlantic Forest, and in this region ephemeral nature of bamboo may mean that protected areas have to be suitably large and contiguous with other areas of appropriate habitat to allow local movements in response to periodic bamboo die-offs.

**Bibliography.** Aleixo (1999), dos Anjos & Boçon (1999), Belton (1985), Cory & Hellmayr (1924), Fraga & Narosky (1985), Hayes (1995), Ihering (1914), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Kratter *et al.* (1993), Nacinovic & Schloemp (1992), Parker (2003a), de la Peña (1988, 2001b), Pereyra (1951), Remsen *et al.* (1986), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1967), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1979b), Zimmer (2003a).

Genus *MACKENZIAENA* Chubb, 1918

5. Large-tailed Antshrike

*Mackenziaena leachii*

**French:** Batara de Leach

**German:** Langschwanz-Ameisenwürger

**Spanish:** Batará Pintado

**Taxonomy.** *Thamnophilus leachii* Such, 1825, Rio de Janeiro, Brazil.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Relationships uncertain; may not be very closely allied with *M. severa*. Monotypic.

**Distribution.** SE Brazil (EC Minas Gerais, S Espírito Santo and SW São Paulo S to N & C Rio Grande do Sul), E Paraguay (Caaguazú, Alto Paraná, Caazapá, Itapúa) and NE Argentina (Misiones).

**Descriptive notes.** 25-26 cm; 58-62 g. Tail long and full. Male is black, with small white spots on crown, nape, upperparts and sides. Female is mostly brownish-black, forehead rufous, crown rufous with black feather edgings; upperparts spotted pale buff, wings barred pale buff; underparts heavily spotted buffy white, crissum barred buffy white. Subadult resembles female, but pale spots larger throughout, becoming bars on belly, and tail faintly barred. **Voice.** Loudsong a long (e.g. 4 seconds), ascending and then descending series of 15-21 evenly spaced, clear, loud, limp whistles, beginning softly, increasing

immediately in intensity, and falling off at end. Calls include a raspy snarl, a short hiss, and long and short downslurred whistles.

**Habitat.** Dense thickets of often bamboo-rich forest, from lowlands to 2150 m. Primarily at higher elevations in N of range, where most common in foothill and montane forest, and associated mainly with extensive stands of bamboo, particularly where dense undergrowth present at forest edges. In S of range, where it occurs down to near sea-level, favours degraded forest (including bamboo-dominated secondary scrub), scrubby dry forest, stunted semi-humid *serra* woodland, and thickets at forest edge.

**Food and Feeding.** Variety of large insects, particularly orthopterans and large lepidopteran larvae, and other arthropods; also snails and slugs; reported to take small vertebrates such as frogs, lizards, snakes, and nestling birds, as well as eggs. Forages singly and in pairs, mostly at 0-5 m above ground, progressing through dense thickets of bamboo and shrubbery with short hops separated by pauses to scan foliage for prey; hops through debris on the ground, perches on vertical bamboo stems. Items gleaned by reaching out, up or down to foliage and branch and stem surfaces; terrestrial prey or flushed arboreal prey pounced on from above. Larger items beaten repeatedly against branches before being consumed.

**Breeding.** Nothing known.

**Movements.** Presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Populations are found in several parks and reserves, including Itatiaia, Aparados da Serra, Serra dos Órgãos, Caraca and Iguaçu National Parks and Caratinga Biological Station, all in Brazil, Iguaçu National Park, in Argentina, and Caaguazú and San Rafael National Parks, in Paraguay. Relatively small range of this species and the fragmented nature of remaining Atlantic Forest are, however, causes for concern, as it appears that this antshrike does not survive in small residual forest patches in this region.

**Bibliography.** dos Anjos (2001a), dos Anjos & Boçon (1999), Belton (1982, 1985), Cory & Hellmayr (1924), Fraga & Narosky (1985), Hayes (1995), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Lowen *et al.* (1997), Pacheco & Whitney (1997), Parker (2003a), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1984d), Zimmer (2003a).

6. Tufted Antshrike

*Mackenziaena severa*

**French:** Batara othello

**German:** Schwarzmasken-Ameisenwürger

**Spanish:** Batará Copetón

**Taxonomy.** *Lanius severus* M. H. K. Lichtenstein, 1823, São Paulo, Brazil.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. May be more closely allied with species in genus *Frederickena* than with *M. leachii*. Monotypic.

**Distribution.** SE Brazil (SE Bahia, EC Minas Gerais and W São Paulo S to N Rio Grande do Sul), E Paraguay (Amambay, Canindeyú, Alto Paraná, Caazapá, Itapúa) and NE Argentina (Misiones).

**Descriptive notes.** 21-22 cm; 52 g, 80 g. Long crest typically held compressed. Male is sooty grey; forehead and crest blackish, wings brownish-black. Female is blackish-brown; forehead and crest rufous, upperparts barred cinnamon, underparts barred pale buff, tail faintly barred. Subadult male resembles adult, but more brownish, including crest. **Voice.** Loudsong a series of 3-12 (typically 6)

**Food and Feeding.** Variety of large insects and other arthropods; also reported to take snails, slugs, and small vertebrates such as frogs, lizards, snakes and nestling birds, as well as eggs. Forages individually or in pairs in dense vegetation, particularly in bamboo thickets and vine clusters

loud countable whistles that rise in pitch while becoming shorter, occasionally ending on lower-pitched note. Calls include emphatic, loud, raspy snarl, usually downslurred, and a clear, downward-inflected whistle c. 1 second long.

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest and second growth, primarily in dense vine tangles, thickets and stands of bamboo, from sea-level to 1400 m. Also occupies even highly degraded forest patches, overgrown orchards, eucalyptus (*Eucalyptus*) stands, and banana plantations, particularly where these are regenerating with dense stands of bamboo.

surrounding larger trees, at 0-3 m, occasionally to 10 m above ground; progresses sluggishly by short leaps among mostly vertical or angled perches, with intervening pauses to scan for prey. Food items gleaned directly from leaf, stem and branch surfaces, less frequently from the ground, by a quick stabbing motion of the bill; occasionally flutters short distances to attack prey that are out of reach.

**Breeding.** Nest undescribed. Eggs described as having clear ground colour, with dull, mottled dark lilaceous spots and some grey lines at pointed end.

**Movements.** Presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Several large parks and reserves exist in the relatively small range of this Atlantic Forest bird, e.g. Itatiaia and Serra dos Órgãos National Parks, in Brazil, and Iguazú National Park, in Argentina. It also persists in a number of degraded, secondary habitats down to sea-level. Probably less threatened by environmental disturbance than is any of the other large antshrikes endemic in this region.

**Bibliography.** dos Anjos (2001a), Belton (1985), Cory & Hellmayr (1924), Fraga & Narosky (1985), Haffer (1987), Hayes (1995), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Krügel & dos Anjos (2000), Machado & Lamas (1996), Parker (2003a), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1967), Sick (1993, 1997), Stotz *et al.* (1996), Willis (1979b, 1984d), Zimmer (2003a).

inches 4  
cm 10

# Genus *FREDERICKENA* Chubb, 1918

## 7. Black-throated Antshrike

### *Frederickena viridis*

**French:** Batara à gorge noire

**Spanish:** Batará Gorginegro

**German:** Schwarze Ameisenwürger

**Taxonomy.** *Thamnophilus viridis* Vieillot, 1816, Cayenne, French Guiana.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Considered to form a superspecies with *F. unduligera*. Monotypic.

**Distribution.** SE Venezuela (Bolívar), the Guianas and NE Amazonian Brazil (Amapá, Pará, and Amazonas N of R Amazon and E of lower R Negro).

**Descriptive notes.** 19–20 cm; 65–75 g. Heavy bill, crest. Male is mostly slate-grey, with black head, throat and breast, faint white bars on tail. Female has crest, nape, upperparts and wings rufous; forehead, side of head, underparts and tail barred blackish-brown and pale buff to white, flanks tinged rufous. Subadult male is like female below, but upperparts mixed grey and brown. **VOICE.** Loudsong a series of 6–15 (typically 10–11) long, plaintive, downward-inflected whistles so closely spaced that they almost run together, initial notes often softest in intensity. Call a long (e.g. 1 second), nasal, downward-inflected churr.

**Habitat.** Understorey of lowland evergreen forest, to 700 m. Appears to be more common in habitats based on sandy soil. Particularly associated with densely vegetated light-gaps, such as treefalls, within primary forest.

**Food and Feeding.** Not well known. Feeds on a variety of insects and other arthropods, including lamellicorn beetles (Lamellicornia), ants, larvae of Lepidoptera, and spiders. Forages individually or in pairs, on or near the ground in dense vegetation, progressing by heavy hops separated by pauses to scan for prey. Reaches out, up or down to glean prey directly from leaf, stem or vine surfaces with a quick stabbing motion of the bill; occasionally makes jumping, upward-directed sallies to glean items from undersides of overhanging vegetation. One female observed at length in Venezuela foraged mostly on the ground in an area with heavy leaf litter, tossing leaves noisily with its bill and probing deliberately in the litter for several seconds at a time, before hopping to another spot; it frequently hopped up several centimetres above ground on to vertical saplings to scan, then dropped back down; also foraged the length of a rotting log, picking at the moss and bark before hopping back down to forest floor. One published record of ant-following, from Brazil (near Manaus): an individual followed a swarm of army ants (*Eciton burchelli*) in dense understorey for 50 minutes, staying 0.2–1.5 m above ground, waggled its tail from side to side, peered up at overhead fronds and leaves, and also scanned the ground, darting rapidly from one perch to another; once, sallied to ground and supplanted *Gymnopithys rufigula*.

**Breeding.** Little known. Oct–Mar in Surinam. Single nest described, an open basket in fork of twiggy branches in low shrub, within shaded understorey. Clutch 2 eggs, creamy white, with purplish hairlines and a few larger spots of same colour.

**Movements.** Presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Seemingly an uncommon to rare, low-density species throughout most of its range, which includes large areas of intact suitable habitat. Occurs in Imataca Forest Reserve and El Dorado, in Venezuela.

**Bibliography.** Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Haffer (1987), Haverschmidt & Mees (1994), Hilty (2003a), Isler & Whitney (2002), Mason (1996), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Sick (1993), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Thiollay (1994), Tostain *et al.* (1992), Willis (1977, 1984d), Zimmer (2003a).

## 8. Undulated Antshrike

### *Frederickena unduligera*

**French:** Batara ondé

**German:** Dunkelbrauner Ameisenwürger

**Spanish:** Batará Ondulado

**Taxonomy.** *Thamnophilus unduliger* Pelzeln, 1868, Rio Içanna, north-west Brazil.

Genus presumed related to *Thamnophilus* on basis of external morphology, especially the strongly hooked bill, but supporting molecular or other evidence unavailable. Considered to form a superspecies with *F. viridis*. Races defined on basis of female plumages, but racial assignment of specimens often difficult because of extensive individual (though possibly age-related) variation, even among females from same locality; geographical limits of *fulva* and *diversa* are based on preliminary vocal analysis; re-examination of taxa required, and molecular and vocal analysis likely to prove most useful. Four subspecies recognized.

**Subspecies and Distribution.**

*F. u. unduligera* (Pelzeln, 1868) - NW Amazonian Brazil on upper R Negro, possibly extending S to N bank of R Solimões.

*F. u. fulva* J. T. Zimmer, 1944 - SE Colombia (E Cauca, W Caquetá, W Putumayo), E Ecuador and E Peru (N of R Maranhão and R Amazon), possibly extending E into Brazil (Amazonas N of R Solimões).

*F. u. diversa* J. T. Zimmer, 1944 - E Peru (S of R Maranhão and R Amazon) and NW Bolivia (S La Paz, extreme S Beni).

*F. u. pallida* J. T. Zimmer, 1944 - SW Amazonian Brazil (Amazonas S of R Amazon), probably also NC Bolivia (E Pando).

**Descriptive notes.** 23 cm; 75–85 g. Prominent crest; iris colour varies from brown to pale yellow, possibly related to age or population, or to both. Male is black, with irregular fine whitish barring except on throat. Female is cinnamon with wavy black barring, except forehead and crest barred rufous and black, tail black with narrow grey bars. Subadult male is like female but more heavily barred, except for lightly barred belly centre contrasting sharply with rest of plumage. Race *fulva* is most heavily barred and darkest in coloration; *pallida* is palest, female unbarred on mantle and underparts; *diversa* is intermediate between previous and nominate, iris pale yellow

(always?). **VOICE.** Loudsong varies regionally: race *fulva* gives a long series (e.g. 7–20 notes, 4–5 seconds) of plaintive notes, starting soft and downslurred, then evenly spaced and up-slurred; *diversa* a rapidly delivered, long series of short notes (e.g. 15–19 notes, 2–5 seconds) that gradually increase in pitch and intensity; recordings of loudsongs of other populations too few to generalize. Typical call a long (e.g. 1 second), nasal, downward-inflected churr; other recorded calls include a squeal followed by a sharp note and short scratchy call repeated in short series, but these may be restricted to a single population.

**Habitat.** Dense understorey of lowland evergreen forest, to 1100 m. Almost always associated with dense thickets of vegetation within primary forest, particularly in viny light-gap tangles around treefalls and stream edges; also in dense *Heliconia* thickets and tangles in regenerating *Cecropia* woods in low-lying areas. Seldom away from heavy cover.

**Food and Feeding.** Not well known. Feeds on a variety of insects, including beetles (Coleoptera), katydids and grasshoppers (Orthoptera) and hairy caterpillars. Forages individually or in pairs, on or within 3 m of the ground, usually in tangles of branches and vines of fallen trees and associated light-gap second growth; progresses by heavy hops, with long pauses to scan for prey. A male in Ecuador was observed reaching up to glean prey from undersides of green leaves, and executing upward-directed, looping sallies of up to 1.5 m to undersides of dead leaves and branches, all within the confines of a large fallen tree. Other individuals seen to search for prey by hopping along fallen trunks, clambering through vine tangles, or moving through a dense stand of saplings on vertical perches. Crest may be raised and lowered between hops; frequently swings tail sideways in jerky manner, similar to tail movements of nunlets (*Nonnula*). Although not usually associating with mixed-species flocks, may briefly accompany flocks moving through its territory. One published record of ant-following, from Colombia (Umbria, in Putumayo): a bird followed an *Eciton burchelli* swarm for 1 hour through a streamside vine tangle, staying 1–4 m above ground in vines and persistently wagging its tail from side to side; once supplanted *Pithys albifrons*, but looked down to zone of ants very little.

**Breeding.** No information.

**Movements.** None recorded; presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Seemingly an uncommon to rare, low-density species throughout most of its range, which includes vast areas of intact suitable habitat. This encompasses some large protected areas, e.g. Yasuni National Park, in Ecuador, and Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru. This antshrike is probably an indicator of high-quality forest; is generally absent from disturbed areas.

**Bibliography.** Álvarez (1994), Alverson *et al.* (2001), Cory & Hellmayr (1924), Foster *et al.* (1994), Haffer (1987), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Parker (2003a), Parker & Bailey (1991), Parker *et al.* (1991), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Stotz *et al.* (1996), Tallman & Tallman (1994), Terborgh *et al.* (1984), Willis (1984d), Zimmer, J.T. (1944), Zimmer, K.J. (2003a).

# Genus *TARABA* Lesson, 1830

## 9. Great Antshrike

### *Taraba major*

**French:** Grand Batara

**German:** Weißbrust-Ameisenwürger

**Spanish:** Batará Mayor

**Taxonomy.** *Thamnophilus major* Vieillot, 1816, Paraguay.

Relationships uncertain; relationship to the *Thamnophilus doliatus* complex suggested by vocalizations and by barred plumage of juvenile. Two main plumage types, one N & W of Andes (races *melanocrissus*, *obscurus*, *transandeanus*, *granadensis*), the other E of Andes (remaining races); the two populations may merit separate species status if apparent parapatry in Venezuela (Miranda) and possibly significant vocal differences are substantiated. Otherwise, plumage differences in populations of Central America and the Pacific slope appear to be clinal, and recognition of geographical races possibly not warranted; further study required. Plumage and vocal differences of races E of Andes more substantial, but careful analysis required to determine extent of intergradation and constancy of characters. Ten subspecies recognized.

**Subspecies and Distribution.**

*T. m. melanocrissus* (P. L. Sclater, 1860) - Caribbean slope from E Mexico (E San Luis Potosí S to N Oaxaca, Tabasco and N Chiapas) S to W Panama (Bocas del Toro, in Almirante Bay region).

*T. m. obscurus* J. T. Zimmer, 1933 - W Costa Rica (Pacific slope), Panama (except Almirante Bay region) and W Colombia (middle Cauca Valley, and Pacific slope except extreme SW).

*T. m. transandeanus* (P. L. Sclater, 1855) - Pacific slope of extreme SW Colombia (Nariño), W Ecuador, and extreme NW Peru (Tumbes).

*T. m. granadensis* (Cabanis, 1872) - N & C Colombia (Caribbean slope from Magdalena S to Córdoba, S in Magdalena Valley to Tolima, and base of E Andes in Arauca, Casanare, Boyacá and Meta) and NW Venezuela (Zulia and Táchira E to W Miranda).

*T. m. semifasciatus* (Cabanis, 1872) - extreme E Colombia (Vichada), and NE & S Venezuela (E Miranda E to Paria Peninsula, and S of R Orinoco), Trinidad, the Guianas, and NE & SC Amazonian Brazil (S to R Negro and R Amazon, and S of R Amazon, from extreme E Amazonas E to W Maranhão and S to N Mato Grosso and NW Goiás).

*T. m. duidae* Chapman, 1929 - Mt Duida, in Amazonas, S Venezuela.

*T. m. melanurus* (P. L. Sclater, 1855) - SE Colombia (Caquetá, Putumayo, Amazonas), E Ecuador, E Peru and SW Amazonian Brazil (S of R Amazon in W Amazonas and Acre E to middle R Purus and N bank of R Abunã).

*T. m. borbae* (Pelzeln, 1868) - SC Amazonian Brazil (E Amazonas along lower R Purus and R Madeira, and extreme N Rondônia).

*T. m. staturus* (M. H. K. Lichtenstein, 1823) - E & NE Brazil (E Maranhão E to Pernambuco and S to E Minas Gerais and Espírito Santo).

*T. m. major* (Vieillot, 1816) - N & E Bolivia, SC Brazil (S Mato Grosso, S Goiás, W Minas Gerais, Mato Grosso do Sul and W São Paulo), W Paraguay (E to both banks of R Paraguay) and N Argentina (S to Córdoba and N Buenos Aires).

**Descriptive notes.** 19–20 cm; 50–70 g. Large bill; prominent crest; red iris. Male nominate race has upperparts mostly black, black extending to below eye on side of head; large white wing-covert spots forming bars, white edges of primaries, white spots on outer tail; white intersecular patch, often concealed; underparts white, flanks tinged grey. Female has crown and tail rufous, lores and ear-coverts browner, upperparts reddish yellow-brown, wing edgings pale; underparts white, tinged cinnamon except on centre of belly, crissum light cinnamon. Juvenile is barred above and below with cinnamon or buff, barring maintained indistinctly in subadult. Races N & W of Andes differ from nominate in male lacking white in upperparts and tail except for wing-covert spots (occasionally white tips on outer rectrices), varying amounts of black and grey on crissum and flanks, female on average darker from N to S, those to E & S differ mostly in number, width and depth of tailbars and extent of grey on rear underparts, females varying in colour intensity corresponding to whiteness of male: *melanocrissus* male has black of head extending below gape, black crissum; *obscurus* is similar but crissum feathers tipped white; *transandeanus* has more white tips on crissum; *granadensis* male has black on head side not extending below gape, crissum even more extensively white; *stagus* has most white on tail, widest wing edgings, least grey on flanks and crissum, female palest; *semifasciatus* has least white on tail, no or thin white wing edgings, deeper grey on crissum; *duidae* resembles previous but larger, female is darker with underparts indistinctly streaked and barred blackish; *borbae* has moderate white on tail and wings, light grey crissum; *melanurus* male has tail black but crissum white (sometimes dusky feather centres), flanks white. **Voice.** Loudsong a long, accelerating series of c. 40 notes, 5–14 seconds, usually ending in a snarl; typically shorter and often without final snarl in races N & W of Andes; race *stagus* often doubles the snarl; shorter, slower-paced version, usually lacking the snarl, is also delivered by some races, especially by females. Calls vary geographically, include long decelerating rattle sometimes ending with a distinct note, shorter rattles often repeated rapidly, a decelerating rolling series of whistles, evenly paced series of harsh notes and of more musical notes, downslurred growl, and somewhat clear, high-pitched whine.

**Habitat.** Understorey of dense thickets in gallery forest, savanna woodland, second growth, and edges and clearings in evergreen forest, mostly below 1000 m, locally to 2200 m. Race *stagus* found in deciduous *caatinga* woodland in NE Brazil; in SC Brazil, nominate race is particularly common in swampy stands of savanna woodland and shrubby borders of gallery forest in the Pantanal region.

**Food and Feeding.** Feeds on a variety of insects, other arthropods, and snails and other molluscs; also small vertebrates, including lizards, frogs, tadpoles, minnows, small mammals; also takes vegetable matter. Regional variation in diet appears to be substantial. Stomach contents from Brazil include beetles of nine groups (Halticinae, Carabidae, Rutelidae, Melolonthidae, Elateridae, Curculionidae, Tenebrionidae, Scarabaeidae, Brentidae); true bugs (Pentatomidae, Cicadidae); adults, larvae and pupae of hymenopterans (Formicidae, Chalcididae, Vespidae, Apoidea); also orthopterans (Tettigoniidae, Gryllidae, Acrididae), termites (Termitidae), diplurans (Spirostreptidae), lepidopteran larvae, dipteran larvae (Stratiomyidae, Brachycera), snails (Gastropoda); and a small fruit. Stomachs of birds from an island in the R Paraná, in Argentina, contained seeds, crustaceans (Trichodactylidae), insects (especially Hymenoptera and Coleoptera), arachnids, molluscs (especially Ampullariidae), and small mammals (Rodentia). Birds from

Surinam had eaten Hemiptera, Heteroptera, Coleoptera (Halticinae), Hymenoptera (Formicidae, Chalcididae, Vespidae) and Orthoptera (Acrididae). Individuals or pair-members forage in dense thickets and vine tangles, from the ground to 5 m up, seldom higher, almost always remaining within cover, and progressing sluggishly by short, heavy hops, pausing between movements to scan for prey. Reaches or sometimes jumps up to glean prey directly from leaf, stem, vine and branch surfaces, also routinely drops from low perches to take prey from ground. In the Pantanal region of Brazil has been observed foraging in the open, using leaves of water hyacinths as platforms from which to extract aquatic insect larvae, frogs, tadpoles and minnows from shallow pools. Sometimes joins mixed-species flocks, particularly in gallery forest and deciduous *caatinga* woodland. Occasionally attends swarms of army ants (both *Eciton burckhelli* and *Labidus praedator*), generally staying 1–5 m above ground and gleaning prey from foliage, vines and branches. In Trinidad, where obligate ant-following antbirds are absent, it behaves like one of those, perching low above the swarm and repeatedly sallying to ground to seize prey flushed by the ants; also very aggressive in supplanting tanagers (Thraupidae), woodcreepers (Dendrocolaptidae) and conspecifics attending swarms.

**Breeding.** Apr–Jul in Costa Rica, Mar and May–Jul in Trinidad, Jan–Jun in Surinam, Jan–Apr in Brazil (Pará) and Oct–Dec in Argentina. Nest in Argentina a suspended cup 7–11 cm in height, 9–14 cm in external diameter, of vegetable fibres tied to two parallel or forked branches, 1–2.1 m above ground, with fibres, stems, straws and a few small leaves and lichens mixed in, the structure being somewhat porous; in Brazil a deep cup suspended from branch fork, well constructed of strong, black fibres, and without green ornamentation; in Costa Rica a bulky cup 15 cm high and 12.5 cm in diameter, suspended by rim, with a frame of coarse dry vines supporting a middle layer of strips of monocot leaves, lined with thinner vines, 1.5–2.5 m up in thicket, often near edge; in Surinam an open cup placed between branches of a shrub; in Trinidad a deep, pensile cup suspended below a horizontal fork or crossed vines, usually within 3 m of ground, strongly woven of black horsehair-like fibres or grass stems, but no distinct lining and the bottom thin enough that eggs can be seen through nest from below. Normal clutch 2 or 3 eggs, 3 more common in extreme S of range, colour and pattern geographically variable, generally dull or creamy white to pale buff, variably blotched and streaked with blackish, chocolate-brown, ash-grey, purplish, vinaceous-brown, cinnamon and/or pale lilac, markings typically concentrated at larger end (sometimes forming darker crown or wreath); incubation by both sexes during day, by female at night, period 17–18 days; nestling period 12–13 days in Costa Rica. In Argentina, nests frequently parasitized by Shiny Cowbirds (*Molothrus bonariensis*).

**Movements.** Presumed resident throughout most of range; some ringing evidence suggests possible seasonal movements in N Argentina.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its extensive range. Occurs in several protected areas. Its preference for a variety of edge and second-growth habitats makes it a low-sensitivity species. Exception is race *stagus* of NE Brazil, which is reliant on threatened deciduous forest and tall *caatinga* habitats.

**Bibliography.** Alabarce & Lucero (1977), Belcher & Smoother (1936), Beltzer (1987), Blake & Loiselle (2001), Christiansen & Pitter (1989), Cody (2000), Cory & Hellmayr (1924), Eisentraut (1935), French (1991), Fraga & Narosky (1985), Hartert & Venturi (1909), Haverschmidt & Mees (1994), Hellebrekers (1942), Hilty (2003a), Hilty & Brown (1986), Ihering (1900), Isler & Whitney (2002), Kreuger (1968), Meyer de Schauensee & Phelps (1978), Morales (1999), Nehrhorn (1899), O'Neill & Pearson (1974), Oates & Reid (1903), Oniki (1972a), Oniki & Willis (1972), Parker (2003a), Peixoto Velho (1932), de la Peña (1975, 1983a, 1995), Pereyra (1938), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Schubart *et al.* (1965), Sick (1993), Skutch (1945a, 1946, 1969c, 1976), Slud (1964), Smyth (1928), Sneath (1935), Stiles & Skutch (1989), Stotz *et al.* (1996), Tallman & Tallman (1994), Tostain *et al.* (1992), Wetmore (1972), Willis (1984d), Zimmer, J.T. # Genus *SAKESPHORUS* Chubb, 1918

## 10. Black-crested Antshrike

### *Sakesphorus canadensis*

**French:** Batara huppé **German:** Schwarzgesicht-Ameisenwürger **Spanish:** Batará Crestinegro

**Taxonomy.** *Lanius canadensis* Linnaeus, 1766. Canada; error = Cayenne, French Guiana. Probably forms a superspecies with *S. cristatus* and *S. bernardi*. Race *pulchellus* appears to be morphologically and vocally distinct from others and may deserve species status; this taxon and proposed races *phainoleucus* (Río Chaco, in N Colombia) and *paraguanae* (Paraguana Peninsula, in NW Venezuela) appear to intergrade, and are better merged. Differences among some or all of the other races may be clinal, and individual plumage variation within each substantial; distributional limits therefore unclear. Six subspecies recognized.

#### Subspecies and Distribution.

*S. c. pulchellus* (Cabanis & Heine, 1859) - N Colombia (Caribbean slope from Guajira S to N Chocó, lower Magdalena Valley S to S Santander) and extreme NW Venezuela (Zulia, W & C Falcón, Lara).  
*S. c. intermedius* (Cherrie, 1916) - E Colombia (Vichada and Meta) and Venezuela N of R Orinoco (E Falcón, Portuguesa and Apure E to Anzoátegui).  
*S. c. trinitatis* (Ridgely, 1891) - NE & S Venezuela (Sucre, Monagas, Delta Amacuro and S of R Orinoco, Bolívar and N Amazonas), Trinidad and Guyana.  
*S. c. canadensis* (Linnaeus, 1766) - Surinam and coastal French Guiana.  
*S. c. fumosus* J. T. Zimmer, 1933 - SW Venezuela (S Amazonas) and extreme N Brazil (N Roraima, extreme N Pará).  
*S. c. loretoyacuensis* (Bartlett, 1882) - locally in NW Amazonian Brazil (along R Negro, R Branco and R Solimões), extreme SE Colombia (SE Amazonas) and NE Peru (along R Amazon, lower R Marañón and R Ucayali).

**Descriptive notes.** 14-15.5 cm; 22-27 g. Crested. Male nominate race has head, throat and centre of breast black, a few white speckles around bill, white band on nape down to breast side; upperparts cinnamon-brown; wings and tail black, edged white, white spots on tips of outer tail feathers; lower underparts whitish-grey, greyer on flanks and crissum. Female has crown rufous, forehead paler with black feather bases, greyish face, cinnamon nape and neck side, upperparts as male; wings and tail brownish-black, edged white on tertials and buffy white on primaries, tail edged and tipped white; breast cinnamon, streaked blackish.

ish, throat and posterior underparts whitish, tinged buff. Subadult male resembles female, may be sexually mature in that plumage. Races vary in darkness and colour intensity: *pulchellus* is palest, with extensive white speckling within black hood, upperparts pale cinnamon with sometimes few black streaks, much white on wings and tail, extensively white below, female pale with breast unstreaked; *fumosus* is darkest, upperparts blackish-brown (sometimes verging on black), only a hint of white surrounding black hood, underparts slate-grey, minimal white on tail, female dark with breast heavily streaked; *loretoyacuensis* resembles previous, but male nape and underparts more like nominate; *intermedius* and *trinitatis* are very similar to nominate. VOICE. Loudsong a series of c. 10-15 notes, initially flat with complaining quality, then rising in pitch while accelerating rapidly; also a variable, more slowly delivered (e.g. 21 notes in 9 seconds) series of simple notes that sometimes accelerates slightly. Calls include a complex downslurred note that sounds as if squeezed out, and abrupt "chup" notes repeated often; rattle call introduced by a long clear note.

**Habitat.** Understorey and mid-storey of deciduous woodland, gallery forest, savanna woodland, and shrubby borders of seasonally flooded *igapó* and *várzea* evergreen forest, to 900 m. Locally in mangroves and dense scrub growing on coastal sand dunes, especially in coastal Surinam and French Guiana; in thickets and bushy places in areas of low rainfall in N Colombia (*pulchellus*). Throughout most of range, most common in semi-arid and seasonally deciduous habitats. In humid, forested lowlands is usually restricted to edges with significant shrub cover and abundant vines, often along rivers. Found in gardens and city parks in some areas.

**Food and Feeding.** Feeds primarily on a variety of insects, including true bugs (Hemiptera, Homoptera), beetles (Coleoptera), adult and larval lepidopterans, orthopterans, as well as other arthropods, particularly spiders; at least occasionally, also takes small lizards, and fruit (Loranthaceae, *Capsicum*). Forages singly or in pairs, or sometimes with mixed-species flocks, from ground to heights of 10-15 m, concentrating especially in vine tangles and dense foliage, progressing by short hops separated by pauses to scan for prey. Less sluggish than larger antshrikes, with shorter pauses between hops, more frequent changes of direction. Reaches out, up or down to perch-glean prey from leaf, vine, stem and branch surfaces, occasionally making a short jump or wing-assisted hop upwards to take an item from underside of overhanging leaf; also drops from low perches to take prey from ground.

**Breeding.** Jun-Sept in Venezuela, May-Jul in Trinidad, Mar-May in Guyana, Dec-Jul in French Guiana; breeds throughout year in Surinam (nests with eggs found in all months except May, Jul and Oct), with pairs documented as nesting twice in one year. Nest in Trinidad a deep, pensile cup suspended below horizontal fork or crossed vines 2-9 m above ground, and strongly woven of black, horsehair-like fibres, but porous in construction with eggs visible through nest from below; in Venezuela a thin-walled cup, rather loosely though neatly woven, suspended in fork of horizontal twig; in Surinam a neatly built, open basket of fine grasses, built by both sexes, moss and spider webs used in construction of inner cup, suspended in fork between twigs of low shrub, nest reused for second brood. Courtship feeding before eggs laid recorded in Surinam. Normal clutch 2 eggs, sometimes 3, whitish or pinkish with variable amounts of purplish, chestnut or brown blotches or streaks; incubation shared by both sexes during day, only by female at night, period in Surinam 14 days; nestlings fed and brooded by both sexes, but only female broods at night; faecal sacs of nestlings swallowed by parents or, if large, carried away from nest.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Generally common throughout its large range. Occurs in Amacayacu National Park, in SE Colombia. Utilization of variety of habitats, including many second-growth and disturbed habitats, buffers this species against any potential threats. Some local populations, particularly those restricted to dry forest, may, however, prove more sensitive. **Bibliography.** Avelado & Pérez (1994), Belcher & Smooker (1936), Cherrie (1916a), Cory & Hellmayr (1924), Darlington (1931), Dugand (1947), French (1991), Haverschmidt (1953, 1965), Haverschmidt & Mees (1994), Hellebrekers (1942), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Junge & Mees (1958), Kreuger (1968), Nehrkorn (1899), Novaes (1980), Pacheco (1995), Reynaud (1998), Ricklefs (1976), Ridgely & Tudor (1994), Ridgely (1911), Schäfer & Phelps (1954), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Tostain (1986a, 2003), Tostain *et al.* (1992), Young (1925), Zimmer, J.T. (1933c), Zimmer, K.J. (2003a).

## 11. Silvery-cheeked Antshrike

### *Sakesphorus cristatus*

**French:** Batara à joues argent **German:** Silberwangen-Ameisenwürger **Spanish:** Batará Crestado

**Taxonomy.** *Thamophilus cristatus* Wied, 1831, Bahia, Brazil.

Probably forms a superspecies with *S. canadensis* and *S. bernardi*. Monotypic.

**Distribution.** NE Brazil in C Ceará. SE Piauí, W Pernambuco, Bahia (except coast) and N Minas Gerais (S to upper São Francisco Valley).

**Descriptive notes.** 14 cm. Crested. Male has forehead, crest, anterior face, throat and centre of breast black, rest of head and underparts greyish-white; back drab brown; wings and tail black, wing-coverts tipped white, remiges edged cinnamon, tail spotted and tipped white. Female differs in having forehead and crown rufous, rest of head and underparts pale buffy brown, remiges browner, tail rufous-brown. VOICE. Loudsong a short series (e.g. 10 notes, 2-5 seconds), initially sharp and strident, then raspy, often ending in lower-pitched growl; accelerates and then decelerates. Calls include deep clear whistle, and more abrupt clear note

sometimes repeated rapidly 3-4 times.

**Habitat.** Understorey and mid-storey of deciduous forest and arid lowland *caatinga*, to 1100 m. Most common where shrub and tree canopies at least 4-5 m tall, interlacing, and provide fairly continuous cover, as in *mata-de-cipó* woodland. Also found in ecotones between deciduous woodland and patches of ridgetop evergreen forest, particularly where vines abundant.

**Food and Feeding.** Not well known. Feeds on variety of insects and other arthropod prey. Forages individually or in pairs, or sometimes with mixed-species flocks, from ground to heights of more than 10 m, usually remaining within dense cover. Most commonly observed foraging 0-2 m above ground, alternately hopping up on to low, open branches or vines, and then back to ground, always moving slowly and pausing for 1-5 seconds between hops to scan for prey. Prey generally gleaned by reaching upwards to pick items directly from undersides of branches, vines or overhanging leaves; also routinely pounces on terrestrial prey from above. Sometimes hitches upwards through hanging tangles of vines along major trunks, perch-gleaning prey from all leaf and vine surfaces.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Generally fairly common within its small range. Occurs in Cavernas do Peruaçu National Park, in Minas Gerais. *Mata-de-cipó* and taller *caatinga* woodlands are habitats under increasing threat from agricultural conversion, grazing, and cutting for firewood. Creation of reserves that protect large areas of *mata-de-cipó* would benefit present species as well as many of greater conservation concern, such as *Rhopornis ardesiacus* and *Formicivora iberingi*.

**Bibliography.** Cory & Hellmayr (1924), Isler & Whitney (2002), do Nascimento *et al.* (2000), Olmos (1993), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (2003a).

## 12. Collared Antshrike

### *Sakesphorus bernardi*

**French:** Batara de Bernard **German:** Fleckengesicht-Ameisenwürger **Spanish:** Batará Collarejo  
**Other common names:** White-naped Antshrike

**Taxonomy.** *Tamophilus* [sic] *Bernardi* Lesson, 1844, Guayaquil, Guayas, Ecuador.

Probably forms a superspecies with *S. canadensis* and *S. cristatus*. Some plumage differences among Pacific slope populations are inconstant and others appear to be clinal; diagnostic differences of described races *piurae* and *cajamarcae* (SW Ecuador, NW Peru) not discernible, and those forms are therefore merged with nominate, pending further study. Two subspecies recognized.

#### Subspecies and Distribution.

*S. b. bernardi* (Lesson, 1844) - WC & SW Ecuador (Manabí, Guayas including Puna I, El Oro, Loja) and NW & NC Peru (Pacific slope in Tumbes and Piura S to N Ancash).  
*S. b. shumbae* Carriker, 1934 - NC Peru (R Marañón drainage in Cajamarca and Amazonas).

**Descriptive notes.** 16-17 cm, 15-16 cm (*shumbae*); 30-38 g. Male has head, throat and upper breast black, speckled white around bill, white from nape to breast side and remaining underparts; upperparts mostly cinnamon-brown, white interscapular patch; wings and tail black, wing-coverts with white edges and spots, flight-feathers edged whitish-buff, tail edged and spotted white; on Pacific slope, some males more extensively speckled white on forehead, some with less black and more white on throat and breast. Female has rufous crown sometimes intermixed with black, forehead and side of head speckled dark brown on dusky white, broad band on nape and remaining underparts buffy white, wings blackish-brown, wing-coverts and flight-feathers edged and spotted buffy white, tail rufous; on Pacific slope, some females have forehead more extensively speckled white, and some have hindcrown or even entire crown black, and wing-covert tips and flight-feather edgings vary from almost white to yellow-ochre. Race *shumbae* has extensive white speckling

around bill, black of throat and breast reduced to patches with white extending through malar region, feather centres on back dark, female has crown entirely rufous, grizzled white on forehead extending over eye, underparts extensively white. **VOICE.** Loudsong a rapidly delivered, short (2-second) series of staccato notes on same pitch, beginning and ending with longer emphatic notes; *shumbae* loudsong faster, final note typically briefer. Other vocalizations include a rattle preceded by abrupt loud note and short pause, a bark followed by a roll, also abrupt clear notes in series, sometimes ending in trill, and long clear

"caw" usually in series of 3-4.

**Habitat.** Understorey to canopy of tropical deciduous forest and lighter woodland, lowland arid scrub, and riparian thickets; locally in coastal mangroves. Mostly below 1000 m, locally to 1850 m.

**Food and Feeding.** Little recorded. Feeds mostly on variety of insects, including true bugs (Hemiptera, Homoptera), orthopterans, beetles (Coleoptera) and lepidopteran larvae, and other arthropods, particularly spiders; may also take nestlings or eggs of small birds, as frequently mobbed by hummingbirds (Trochilidae), seedeaters (*Sporophila*) and grassquits (*Tiaris*). Individuals or pairs generally forage apart from mixed-species flocks, often hopping on ground beneath thickets and taking prey directly from leaf litter, alternately hopping up on to low perches on open branches or vines to scan before dropping back down. Also works methodically through thickets, vine tangles and foliage to 10 m above ground, seldom higher, progressing by short hops separated by pauses to scan foliage. Terrestrial prey usually pounced on from above; other items gleaned by reaching out, up or down with quick stabbing motions of the bill. During foraging habitually wags tail up and down in a shallow arc, particularly when changing perch.

**Breeding.** Jan-Apr in Ecuador, with all nests started after onset of rainy season; single nest in May in Peru. In Ecuador (12 nests) a deep cup, internal measurements 6-6.5 cm across, 5-6 cm deep, of dead grasses and plant stems without lining, and neatly but loosely woven so that contents visible from outside, suspended 0.74-1.85 m above ground from bifurcating twigs, typically in *arrayan* shrubs, reasonably covered but not well hidden; single known nest in Peru (Lambayeque) a well-made cup, external measurements 11.5 cm across, 8.5 cm deep, made of vine stems (primarily) and leaves, lined with coarse grasses or vine stems, and also including small balls of cotton-like plant fibres, placed c. 2-3 m up in an overo shrub in shade of a tall acacia (*Acacia*). Normal clutch 2 or 3 eggs, creamy white, blotched and streaked boldly with dark chocolate-brown over lavender-brown, usually in a zone around large end, with scattered dots elsewhere; incubation recorded only for female, but probably shared by both sexes, period 15-16 days; chick hatches naked, skin deep purple or reddish-brown, quills sprout in 6-7 days, development so rapid that nestling well feathered at 9 days; nestling period at one nest 11-12 days. Of 11 nests in Ecuador, 3 successful, giving productivity of 8 young from total of 28 eggs; 4 of those nests, and the one from Peru, were parasitized by Shiny Cowbirds (*Molothrus bonariensis*).

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Tumbesian Region EBA and Marañón Valley EBA. Occurs in Machalilla National Park, in Ecuador. Generally fairly common in a variety of arid and semi-arid habitats, including ones subjected to moderate levels of grazing by livestock. Seemingly a low-sensitivity species. Distinctive race *shumbae*, of Marañón Valley, in Peru, needs to be properly censused before its true conservation status can be determined; at present it is best considered data-deficient.

**Bibliography.** Behrstock (2003), Cory & Hellmayr (1924), Friedmann & Kiff (1985), Isler & Whitney (2002), Marchant (1959, 1960), Parker (2003b), Parker & Carr (1992), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Stotz *et al.* (1996), Zimmer, J.T. (1933c), Zimmer, K.J. (2003a).

### 13. Black-backed Antshrike

#### *Sakesphorus melanonotus*

**French:** Batara à dos noir **German:** Schwarzweißer Ameisenwürger **Spanish:** Batará Dorsinegro

**Taxonomy.** *Thamnophilus melanonotus* P. L. Sclater, 1855, Santa Marta, Magdalena, Colombia. Has historically been considered most closely related to *S. canadensis* on basis of morphology, but is vocally quite distinct. Monotypic.

**Distribution.** Caribbean slope in N Colombia (S & W to N Bolívar) and NW Venezuela (E to Miranda).

**Descriptive notes.** 15-16 cm. Male is black to blackish-brown, except for white edges of scapulars, white interscapular patch, light grey posterior upperparts, wing-coverts broadly tipped white, flight-feathers edged white, graduated tail with white tips and edges of outer feathers, white flanks, lower belly and much of crissum. Female differs in having dark brown crown feathers edged cinnamon, brown upperparts with dark feather centres, brownish-black wing-coverts and wings tipped and edged pale buff to white, rufous-brown tail with whitish tips and edges; underparts pale buff, whitest on belly. Juvenile is like female, but crown blackish-brown; subadult male resembles female, but usually some black feathers emerging. **VOICE.** Four vocalization types recorded. A descending "aawr", repeated at regular intervals, believed to be loudsong; possible alternative loudsong is a short (e.g. 0.8-second) rapid rolling series of notes, all descending in pitch except for lower-pitched introductory note; other calls include two-part "ee-ohr", second part lower in pitch, and abrupt "pip" notes.

**Habitat.** Understorey and mid-storey of deciduous forest, to 500 m; occasionally to 1300 m, in Venezuela. Favours disturbed areas or riparian arroyos with extensive evergreen thickets, within arid woodland, particularly where vines abundant. Appears to require more humid, densely vegetated micro-habitats than *S. canadensis* in regions where the two occur together.

**Food and Feeding.** Little known. Feeds primarily on various insects, including true bugs (Hemiptera, Homoptera: Cicadidae), orthopterans and lepidopteran larvae, and other arthropods. Forages individually or in pairs, mostly 0-6 m above ground, particularly in vine tangles and deciduous thickets, with short hops separated by pauses of up to several seconds to scan for prey. Routinely wags tail slowly up and down while foraging. Reaches out, up or down to glean prey directly from leaf,

stem, vine and branch surfaces; also frequently makes jumping upward sallies to glean items from undersides of overhanging vegetation, or pounces on terrestrial prey from low perches. Occasionally attends army-ant swarms; does not typically associate with mixed-species flocks.

**Breeding.** Little known. Mar-Jul in N Colombia. Nest in Colombia an open, unlined cup, suspended by rim to thorny bush; contained 2 eggs, white, with dark purple smudges and spots almost exclusively in wreath at blunt end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Caribbean Colombia and Venezuela EBA. In Venezuela, occurs in Henri Pittier National Park and also at Chichiriviche, the latter a good base from which to explore nearby Morrocoy National Park. Generally uncommon within its small range. Conversion of much of the dry and semi-deciduous forest of the region to agriculture (particularly pasture for goats) is a potential threat that needs to be monitored. Surveys are required in order better to assess population levels of this species.

**Bibliography.** Allen (1905), Aveledo (1957), Cory & Hellmayr (1924), Darlington (1931), Hilty (2003a), Hilty & Brown (1986), Iafrenco *et al.* (1987), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Schäfer & Phelps (1954), Schönwetter & Meise (1988), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Todd & Carriker (1922b), Vereá & Solórzano (1998, 2001), Willis (1984d), Zimmer (2003a).

### 14. Band-tailed Antshrike

#### *Sakesphorus melanothorax*

**French:** Batara de Cayenne **German:** Schultersfleck-Ameisenwürger **Spanish:** Batará Guayanés  
**Other common names:** Black-throated Antshrike(!)

**Taxonomy.** *Thamnophilus melanothorax* P. L. Sclater, 1857, Cayenne, French Guiana. Relationships uncertain. Monotypic.

**Distribution.** Surinam, French Guiana and NE Amazonian Brazil (Amapá; also one reliable sight record from N of Manaus, in Amazonas).

**Descriptive notes.** 16-17 cm; 31 g (one individual). Male is entirely black, except for concealed white scapular patches, small white wing-covert spots, and a broad white band across tail tip. Female has crown, upperparts, wings and tail bright deep rufous, lower forehead, face, throat and breast black, posterior underparts becoming grey, suffused with reddish-brown on flanks and crissum. **VOICE.** Loudsong a short (e.g. 7 notes, 3 seconds) series of deep, downward-inflected, somewhat muffled notes that speed up and end with two more abrupt notes. Call a muffled, nasal growl, sometimes doubled.

**Habitat.** Not well known. Understorey and, to lesser extent, mid-storey of evergreen forest where dense stands of lianas and other dense growth associated with naturally disturbed areas, such as treefalls; also in areas of human disturbance that have grown over with vegetation. Also found in swampy, bushy depressions and in dense thickets at edges of rivers. May have specialized habitat requirements that remain to be documented in detail. From near sea-level to 550 m.

**Food and Feeding.** Little known. Diet assumed to consist primarily of a variety of insects and other arthropods. Individuals or pairs forage in dense cover, 0-10 m above ground, progressing by short hops separated by pauses of 1-15 seconds to scan for prey. Prey gleaned directly from leaf, vine and branch surfaces, or from ground. Does not regularly associate with mixed-species flocks.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Poorly known, and should perhaps be given conservation status of Data-deficient. Appears to be a rare, low-density species throughout its range. Although its precise habitat requirements are not well understood, on a broad scale, there would appear to be large intact areas of potentially suitable habitat remaining in Surinam, French Guiana and Brazil (Amapá). More research into the habitat requirements and population levels of this species is needed.

**Bibliography.** Cory & Hellmayr (1924), Haverschmidt & Mees (1994), Isler & Whitney (2002), Ridgely & Tudor (1994), Sick (1993), Stotz *et al.* (1996), Thiollay (1994), Tostain (1980a, 1980b), Tostain *et al.* (1992), Willis & Oniki (1988a), Zimmer (2003a).

### 15. Glossy Antshrike

#### *Sakesphorus luctuosus*

**French:** Batara luisant **German:** Trauerameisenwürger **Spanish:** Batará Luctuoso

**Taxonomy.** *Lanius luctuosus* M. H. K. Lichtenstein, 1823, Cametá, Pará, Brazil.

Relationships uncertain. Race *araguayae* may represent the end point of a cline. Two subspecies recognized.

**Subspecies and Distribution.**

*S. l. luctuosus* (M. H. K. Lichtenstein, 1823) - C & E Amazonian Brazil, on both banks and along S tributaries, from EC Amazonas E to Pará (except S R Araguaia drainage) and S to NE Rondônia and N Mato Grosso.

*S. l. araguayae* (Hellmayr, 1908) - S R Araguaia drainage in Tocantins, Goiás and SE Mato Grosso.

**Descriptive notes.** 17 cm; 27-33 g. Prominent crest. Male is black, with dark grey on posterior upperparts and underparts, partially concealed white under scapulars, and large white tail tips. Female differs in having forehead and crest deep chestnut-brown. Subadult male is like female, but crest usually shows emerging black feathers. Race *araguayae* differs from nominate in broader white edges under scapulars, less white at tips of rectrices. **VOICE.** Loudsong a moderately long (3-6 seconds) accelerating series of 8-20 strident clear notes, varying only slightly in pitch. Other vocalizations include a slowly repeated series of downslurred whistles: soft and raspy "caw" notes; also long downslurred whistle, and shorter downslurred whistle that immediately becomes a short rattle.

**Habitat.** Understorey and mid-storey of flooded evergreen forest, riparian forest and adjacent humid second growth in lowlands, below 250 m. Occupies mainly the shrubby, viny, margins of flooded *várzea* and *igapó* forests. Locally common on forested river islands. Also occurs along margins of small tributaries of major rivers that are not subject to extensive flooding.

**Food and Feeding.** Feeds primarily on a variety of insects, including true bugs (Hemiptera), katyids (Tettigoniidae), beetles (including Curculionidae) and lepidopteran larvae, and other

arthropods (particularly spiders). Forages singly or in pairs, only occasionally with mixed-species flocks, in dense thickets (often over water) and vine tangles, from ground level to 15 m up, progressing by short hops separated by pauses of 1-15 seconds to scan for prey. Reaches out, up or down to glean items from all leaf, stem, vine or branch surfaces with quick stabbing motion of the bill; occasionally makes short, upward-directed sallies to take food from overhanging vegetation; also occasionally drops to ground to take terrestrial prey. The crest is typically laid flat when foraging; when agitated, raises crest, raises

and fans tail, and droops wings.

**Breeding.** Only one nest known, found in Dec in SE Pará (R Itacatuas); described as a pendent bag c. 8 cm deep, made of dark, fibrous plant material with some paler, thicker leaves worked into sides, placed c. 1 m from trunk in crown of small tree 3 m tall, the only arboreal vegetation on a small rocky island surrounded by fairly fast-flowing water; both parents fed nestlings.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Generally fairly common throughout its range, which includes extensive areas of suitable habitat, some of which are formally protected, e.g. Cristalino State Park, Araguaia National Park and Caxiuanã National Forest. Reliance on flooded-forest habitat makes this species less prone to disturbance, and its ability to colonize adjacent disturbed second-growth thickets suggests a low sensitivity.

**Bibliography.** Cory & Hellmayr (1924), Isler & Whitney (2002), Oren & Parker (1997), Parker (2003a), Remsen & Parker (1983), Ridgely & Tudor (1994), Sick (1993), Sneath (1913), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Whitney (2003b), Zimmer (2003a), Zimmer, Parker *et al.* (1997).

**Habitat.** Understorey and mid-storey of bamboo-rich evergreen forest and older second growth, at 500-1200 m. Primarily in foothills, and in some areas confined to elevations within the fog belt. Presence of large-leaved bamboo, probably mostly of genus *Merostachys*, a critical component of habitat; in some areas of Brazil, e.g. Itatiaia National Park (Rio de Janeiro) and Iguaçu National Park (Paraná), has been found only in the most extensive stands of *Merostachys*, where the bamboo formed columns that climbed into lower canopy and nearly covered many medium-sized trees. Also found in ecotone between *cerrado* and humid,

older second growth (in Minas Gerais) and in *Araucaria*-dominated forest (in Paraná), but in all cases only where extensive stands of tall bamboo prevalent.

**Food and Feeding.** Diet not well known. Feeds primarily on various insects and other arthropods, particularly spiders; stomach contents of a specimen from Rio de Janeiro included spiders, ants, and many small seeds. Individuals or pairs forage mostly in dense stands of bamboo, 1-10 m above ground, almost always remaining in shaded areas beneath overhanging cover, particularly along larger, horizontal limbs and bamboo stems. Progresses in short hops, with pauses of up to several seconds to scan; more active than larger species of antshrike, with shorter pauses between perch changes, more frequent changes of direction. Reaches out, up or down to glean prey directly from bamboo stems and foliage, and from adjacent vegetation. Frequently makes diagonal upward sallies of up to 1 m to glean prey from undersides of leaves or stems, typically continuing on to different perch to consume the food; also short, vertical sallies to hover-glean from undersides of leaves and stems, before dropping back to same perch. Often associates with mixed-species flocks.

**Breeding.** In Brazil, nest-building in Oct and Nov (Rio de Janeiro) and adult carrying food for young in Dec (Minas Gerais). Both nests under construction were in *Merostachys* bamboo; one c. 7 m above ground, just beneath top of a dense bamboo thicket c. 8 m tall in broken-canopy forest, appeared to be a bowl-like platform supported by several thin, crossing bamboo stems, main material thought to be dead *Merostachys* leaves which both sexes broke from branchlets by grasping and ripping off at base, male also gathered thin pieces of vine and fungal strands (seemingly of *Merasmium*) from surrounding trees.

**Movements.** None recorded; probably chiefly resident, although thought to undertake small-scale movements in response to periodic local die-offs of bamboo.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Atlantic Forest Lowlands EBA. Rare throughout its restricted range; apparently never common. Reliance on bamboo, particularly of genus *Merostachys*, which is known to undergo episodic local die-offs, makes this and other bamboo specialists of the Atlantic Forest particularly vulnerable; such die-offs result in large geographical and temporal discontinuities in availability of suitable habitat. Larger reserves with a diversity of bamboo species, and abundance of extensive bamboo stands at a variety of elevations, are the most likely to retain healthy populations of this antshrike, which appears not to survive in small residual forest patches. Current strongholds seem to be Itatiaia and Serra dos Órgãos National Parks and Desengano State Park, in Rio de Janeiro, Iguaçu National Park, in Paraná, and Iguaçu National Park, in Argentina; also Intervales State Park, in São Paulo. Proposed measures include more extensive surveys to determine the species' true conservation status, and a long-term study of all Atlantic Forest bamboo specialists in order to gain a better understanding of the effects of bamboo cycles on avian populations and ecology.

**Bibliography.** dos Anjos & Boçon (1999), dos Anjos & Graf (1993), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1924), Gai (1950, 1951), Isler & Whitney (2002), Machado (1999), Parker & Goerck (1997), Pearman (2001), Ridgely & Tudor (1994), do Rosário (1996), Sick (1993, 1997), Stattersfield & Capper (2000), Wege & Long (1995), Whitney (2003b), Willis (1989), Willis & Oniki (1993), Zimmer (2003a).

## Genus *BIATAS* Cabanis & Heine, 1859

### 16. White-bearded Antshrike

#### *Biatas nigropectus*

**French:** Batará à poitrine noire **German:** Weißbart-Ameisenwürger **Spanish:** Batará Pechinegro

**Taxonomy.** *Anabates nigro-pectus* Lafresnaye, 1850, Rio de Janeiro, Brazil. Relationships uncertain. Monotypic.

**Distribution.** SE Brazil (SE Minas Gerais, E São Paulo, Rio de Janeiro, W & E Paraná, NE Santa Catarina) and NE Argentina (Misiones).

**Descriptive notes.** 17-18 cm. Semi-erectile crest often held raised. Male has forehead to upper nape and loreal and ocular regions black, with suggestion of white eyeline; chin and side of head below eye white, becoming pale buff on lower nape (nuchal collar sometimes absent); upperparts reddish yellow-brown, wings and tail rufous; lower throat and breast black, posterior underparts clay-coloured. Female differs in having crown rufous-brown, pronounced white eyebrow, no black on throat and breast. **VOICE.** Loudsong a short (e.g. 8 notes, 3 seconds) series of mournful, moderately long notes (about as long as intervals between them), first and last notes typically slightly shorter and at slightly lower pitch. Call a complaining downslurred note, given in pairs or repeated regularly in longer series.

# Genus *THAMNOPHILUS* Vieillot, 1816

## 17. Barred Antshrike

### *Thamnophilus doliatus*

**French:** Batara rayé

**German:** Bindenameisenwürger

**Spanish:** Batará Barrado

**Taxonomy.** *Lanius doliatus* Linnaeus, 1764, no locality = Surinam.

Belongs to a species group which also includes *T. zarumae*, *T. multistriatus*, *T. temepunctatus*, *T. palliatus*, *T. torquatus* and *T. ruficapillus*. Forms a superspecies with first of those and formerly treated as conspecific, but differs in morphology and vocalizations. Taxonomy of present species in need of study and possible revision; races may constitute more than one species; further, plumage varies considerably within many races, apparently in clinal pattern, and comparisons of morphology with molecular and other characters needed to reconfirm validity of many taxa; current treatment tentative. Other described races are *yucatanensis* (S Mexico, N Guatemala) and *pacificus* (W Honduras to W Costa Rica), which appear inseparable from *intermedius*; *fraterculus* (E Colombia, N Venezuela, Trinidad), considered indistinguishable from nominate; and *subradiatus* (E Peru, W Brazil), *novus* (Mato Grosso) and *signatus* (NE Bolivia, SW Brazil), which appear inseparable from *radiatus*. In addition, birds from N Colombia, formerly considered a disjunct population of *nigricristatus*, intergrade with *albicans* and are therefore included with latter. Twelve subspecies recognized.

#### Subspecies and Distribution.

*T. d. intermedius* Ridgway, 1888 - E Mexico (SE from S Tamaulipas and San Luis Potosí and, on Pacific slope, E from Oaxaca), Belize and Guatemala S to W Panama (W Chiriquí, Bocas del Toro).  
*T. d. nigricristatus* Lawrence, 1865 - C Panama (E Chiriquí and S Veraguas E to W San Blas).  
*T. d. eremmus* Wetmore, 1957 - Coiba I, S Panama.  
*T. d. nesiotetes* Wetmore, 1970 - Pearl Is, S Panama.  
*T. d. albicans* Lafresnaye, 1844 - N & W Colombia (Caribbean slope from Antioquia and Córdoba E to La Guajira, and S in Magdalena Valley to Huila).  
*T. d. nigrescens* Lawrence, 1867 - NC Colombia E of Andes (Norte de Santander) and NW Venezuela N of Andes (Zulia, Táchira, W Mérida).  
*T. d. tobagensis* Hartert & Goodson, 1917 - Tobago.  
*T. d. doliatus* (Linnaeus, 1764) - NE Colombia (S to Caquetá and Guiania), Venezuela (except in NW and, apparently, S Bolívar and E Amazonas, but including Margarita I), Trinidad, the Guianas, and N Amazonian Brazil (extreme N Amazonas on upper R Negro, Roraima, Amapá, and N Pará from vicinity of R Trombetas E to Marajó I).  
*T. d. radiatus* Vieillot, 1816 - extreme SE Colombia (S Amazonas), NE Ecuador (Napo), E Peru (except N Amazonas and W Loreto), W & SC Brazil (N bank of R Amazon E to vicinity of R Trombetas and, S of R Amazon, E to right bank of R Tapajós and R Aripuanã in W Pará and S to Acre, Mato Grosso do Sul, W Paraná and São Paulo), N & E Bolivia, Paraguay and N & NE Argentina (Salta, Formosa, Santa Fe, Misiones).  
*T. d. cadwaladeri* Bond & Meyer de Schauensee, 1940 - S Bolivia (Tarija).  
*T. d. difficilis* Hellmayr, 1903 - EC Brazil (E Maranhão, SW Piauí and extreme SE Pará S to E Mato Grosso, W & S Goiás and extreme W Bahia).  
*T. d. capistratus* Lesson, 1840 - E & S Piauí, Ceará and Rio Grande do Norte S to extreme N Minas Gerais and C Bahia.

**Descriptive notes.** 15–16 cm; 24–30 g. Crested; iris typically straw-coloured, but dark in some regions. Male nominate race has bases of central crown feathers extensively white, tips black, feathers on side of crown black, throat, head side and nape streaked black and white; remaining plumage barred black and white, black bars wider on upperparts. Female is very different, with crown dark chestnut, head side and nape black-streaked pale buff, throat whitish with few dark streaks; upperparts, wings and tail rufous, underparts brownish-yellow, belly palest. Subadult male has pale barring light yellowish-brown white, rather than white.

Races vary primarily in extent of white in crown and tail and relative width of white and black bars (especially below) of male, and in darkness of female: *intermedius* male resembles nominate, but varies in darkness of underparts, palest on Pacific slope (“*pacificus*”) and Yucatan Peninsula (“*yucatanensis*”), female typically darker than nominate (but paler and more ochraceous where male paler); *nigricristatus* male has crown black, centre of belly unbarred or faintly barred, female lacks black streaks on throat; *eremmus* and *nesiotetes* resemble previous, but more deeply coloured; *albicans* male has crown black, centre of belly white, remaining underparts sparingly barred, female pale below with throat white, both sexes becoming progressively darker towards Caribbean coast; *nigrescens* is very dark, male with mostly black crown, black bars much broader than white ones; *tobagensis* male is whiter below, female darker below; *radiatus* male has black crown (forecrown variably spotted white) and is whiter below (black bars reduced or absent in belly centre) in S of range, becoming progressively darker to SE (“*novus*”), W (“*subradiatus*”) and N (“*signatus*”), where black throat stripes become narrower, female paler where male paler; *difficilis* resembles previous, but male forecrown with more white, greyer below, female like dark forms; *capistratus* has shorter and thicker bill, chestnut eyes, male crown black, tail with restricted white spots, female with heavily streaked throat, bars on breast, belly whitish; *cadwaladeri* male is pale, belly almost unbarred, female white below, buff tinge on breast and sides. **VOICE.** Loudsong an accelerating staccato series (e.g. 20 notes in 3 seconds, but variable) of sharp nasal notes, begins with soft notes and builds in intensity and slightly in pitch to about halfway into song, ends with long, distinctive, higher-pitched, downward-inflected note; S of R Amazon loudsongs are shorter, accelerate and increase in pitch less initially, but drop more in pitch at end. Variety of calls that appear to vary in repertoires of different races; include a growl, a short “caw”, softened throaty mews and cries, short and long clear whistles; also short series similar to those of trogons (Trogonidae), probably restricted to Central American races.

**Habitat.** Understorey to mid-storey of deciduous forest, second-growth scrub, riparian scrub, river-edge forest and river-island scrub, to 2000 m. Mainly in thickets and shrubby borders at forest edge, often venturing into cultivated areas, gardens and parks with thickets, hedgerows and trees. Occurs in both arid and humid regions, and in many parts of range is something of a habitat generalist. Contrastingly, in C & W Amazonia almost exclusively a river-island bird, in NE Brazil largely confined to deciduous *caatinga* woodland, and in savanna regions usually restricted to gallery-forest edge or isolated areas of savanna woodland. On islands where no congeners present, such as Tobago and Panamanian island of Coiba, occurs in almost all micro-habitats, ranging to crowns of trees. Generally replaced by *T. multistriatus* at higher elevations in Colombia.

**Food and Feeding.** Feeds primarily on insects, including beetles (Coleoptera), true bugs (Hemiptera, Homoptera), orthopterans, ants and lepidopteran larvae, as well as other arthropods (particularly spiders). Stomach samples from Panama contained beetles of several families and subfamilies (Elateridae, Curculionidae, Bruchidae, Alticinae), stink-bugs (Pentatomidae), ants and small seeds; samples from S Brazil (Mato Grosso) included beetles (Cerambycidae, Staphylinidae, Chrysomelidae), hemipterans (Reduviidae, Pentatomidae), hymenopterans (Formicidae, Vespoidea, Meliponidae), and small seeds. In Surinam, recorded as eating various hymenopterans (Formicidae, Myrmicinae, Vespidae, Apidae), coleopterans, lepidopterans and termites (Isoptera), as well as berries and other fruits (Loranthaceae, *Capsicum*). Forages singly and in pairs, mostly in dense cover, from ground to 10 m or more; at least in some regions, appears to obtain insects from unusually wide variety of substrates. Birds feeding at ground level typically stay beneath overhanging vegetation, taking prey from ground and frequently jumping up to low perches to scan, before dropping back down. Progresses through vegetation by short, heavy hops and fluttery flights, with intervening pauses of 1–15 seconds to scan for prey. Often ascends columns of vines and epiphytes along larger trunks, hitching from side to side as it climbs. Reaches out, up and down to glean prey from all sides of leaf, stem, vine, branch and even trunk surfaces with quick stabbing motions of bill. Reported to catch flying termites by making short pursuit-flights low above ground. Although does not typically join mixed-species flocks, birds living in gallery-forest habitats more often associate with such flocks. Occasionally attends army-ant swarms.

**Breeding.** Jan–Jun in Costa Rica, Mar–Aug in Panama, Jan–Jun in Guyana, Feb–Sept in French Guiana, Sept–Dec in Brazil and Argentina; breeds throughout year in Surinam and Trinidad. Nest built by both sexes: in Costa Rica, a deep, thin-walled cup of fine vines, tendrils, fungal rhizomorphs, often a few tufts of green moss on outside, fastened by rim in horizontal fork 1–9 m up in thicket; in Guyana, a hammock-like structure thinly but strongly constructed of fine grass-heads, rootlets and (near human habitation) pieces of string and thread, lined with fine grass and cow hair, slung in horizontal fork within 1 m of ground in dense shrub; in Surinam, an open basket of dried grasses, built in fork between twigs of low shrub; in Trinidad, a deep cup of weed and grass stems (sometimes with coarse grass-blades and vine tendrils) with inner lining of fine fibres, suspended by rim to slender horizontal fork 1–10 m above ground; additional nest descriptions available from most parts of range. Normal clutch 2 eggs, less commonly 1, rarely 3, laid on alternate days, whitish, with scratches, blotches and speckles of chocolate-brown, rufous or purplish-brown either over whole surface or concentrated at thicker end; incubation by both sexes, only female at night, period 14 days in Surinam and S Brazil, 15 days in Argentina; both parents assist in feeding chicks, nestling period 11–13 days in Surinam, S Brazil and Argentina. Nesting success from study of five nests in Argentina was 33.3%; brood parasitism by Shiny Cowbirds (*Molothrus bonariensis*) documented from Argentina.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Generally common throughout its extensive range. Adapted to a variety of second-growth and disturbed habitats, making it a low-sensitivity species. Possible exception is race *capistratus* of NE Brazil, which occupies dry forest and *caatinga* woodland, both of which are threatened habitats.

**Bibliography.** dos Anjos (2001a), Aveledo (1946), Belcher & Smoother (1936), Binford (1989), Blake & Loiselle (2001), Cherrie (1916a), Cody (2000), Cory & Hellmayr (1924), Di Giacomo (1998), Ifrench (1991), Fiebrig (1921), Fraga & Narosky (1985), Griscom (1932a), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hellebrekers (1942), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. *et al.* (1998), Isler, P.R. & Whitney (2002), Keeler-Wolf (1986), Kreuger (1968), Krügel & dos Anjos (2000), Land (1962, 1970), Marino (1993), Monroe (1968), Nehrkorn (1899), Novaes (1960), O’Neill & Pearson (1974), Oates & Reid (1903), Oniki (1988), Oniki *et al.* (2002), Ramo & Busto (1984), Reynaud (1998), Ricklefs (1976), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Rowley (1984), Russell (1964), Schönwetter & Meise (1967), Schubart *et al.* (1965), Siek (1993), Skutch (1969c), Slud (1964), Sneath & Schreiner (1929), Snow & Snow (1964), Stiles & Skutch (1989), Stotz, Fitzpatrick *et al.* (1996), Tostain (1979, 2003), Tostain *et al.* (1992), Wetmore (1972), Willis (1983a, 1984d), Young (1925, 1929), Zimmer, J.T. ## 18. Chapman’s Antshrike

### *Thamnophilus zarumae*

**French:** Batara de Chapman **German:** Fahlflanken-Ameisenwürger **Spanish:** Batará de Chapman

**Taxonomy.** *Thamnophilus zarumae* Chapman, 1921, Zaruma, El Oro, Ecuador.

Belongs to the species group that also includes *T. doliatus*, *T. multistriatus*, *T. temepunctatus*, *T. palliatus*, *T. torquatus* and *T. ruficapillus*. Forms a superspecies with first of those and formerly treated as conspecific, but differs in morphology and vocalizations. Plumage differences between races may be clinal. Two subspecies recognized.

#### Subspecies and Distribution.

*T. z. zarumae* Chapman, 1921 - SW Ecuador (El Oro, Loja) and NW Peru (Tumbes, NE Piura).

*T. z. palambae* J. T. Zimmer, 1933 - NW Peru (SE Piura, E Lambayeque).

**Descriptive notes.** 14–15 cm; 21–23 g. Crested; iris greyish-yellow or brown. Male has forehead heavily spotted black and white, black crown sparsely spotted white, white throat and side of head streaked black; upperparts, wings and tail barred black and white, white bars on rump tinged buff; breast white, thinly barred blackish, posterior underparts pale buff, faintly barred on flanks and crissum. Female has crown dark chestnut-brown, forehead paler, side of head and band behind nape streaked black and pale brownish-yellow, upperparts, wings and tail rufous, wings and tail faintly barred blackish, throat and breast buffy white with faint dusky spotting, remaining underparts buff. Race *palambae* male has white markings on upperparts fainter, lower underparts more heavily barred and tinged ochraceous, female darker-crowned with more barring on sides. **VOICE.** Loudsong constructed of three distinctive parts: an accelerating series of 12–13 sharp nasal notes, 3 longer, louder notes at higher pitch, and short lower-pitched trill. Calls include abrupt “chup”, slightly longer downslurred note, and highly variable squeals.

**Habitat.** Understorey to canopy of semi-arid deciduous forest, adjacent semi-humid forest and secondary scrub, mostly from 800 m to 2100 m, locally to 2650 m. Prefers more densely vegetated and vine-rich micro-habitats. Occurs in dense tangles at forest edge and frequently ventures into semi-open areas; unlike most forms of *T. doliatus*, routinely occupies forest interior as well.

**Food and Feeding.** Not well known. Feeds on variety of insects and other arthropods, including lepidopteran larvae, orthopterans and spiders. Individuals or pairs forage mostly in dense tangles of vegetation, 1-15 m above

ground, progressing by short hops separated by pauses of up to several seconds to scan for prey. Reaches up, out and down to glean items from all leaf, stem, vine and branch surfaces, using quick bill-stabbing motion. A pair in Peru (Tumbes) repeatedly inspected and probed small epiphytic bromeliads scattered along major branches of a large deciduous tree. In Ecuador, observed feeding on berries in upper strata of a tree of the mahogany family (Meliaceae). Frequently associates with mixed-species flocks.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tumbesian Region EBA. Ongoing deforestation, which has been particularly severe in the Ecuadorian parts of this species' tiny range, could become a potential threat. Continued protection of the Tumbes National Reserve, in Peru, would provide an important population reservoir for this species.

**Bibliography.** Best & Clarke (1991), Cory & Hellmayr (1924), Isler & Whitney (2002), Parker *et al.* (1995), Rasmussen *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer, J.L. (1933a), Zimmer, K.J. (2003a).

## 19. Bar-crested Antshrike

### *Thamnophilus multistriatus*

**French:** Batara de Lafresnaye **German:** Streifenameisenwürger **Spanish:** Batará Crestibarrado

**Taxonomy.** *Thamnophilus multistriatus* Lafresnaye, 1844. Bogotá, Colombia.

Belongs to the "*T. doliatus* group", which also includes *T. zarumae*, *T. tenuipunctatus*, *T. palliatus*, *T. torquatus* and *T. ruficapillus*. Morphological characteristics distinguishing races appear to be clinal (with possible exception of *selvae*); likelihood that geographical ranges of most are disjunct, however, suggests need for careful study of differences among them. Four subspecies recognized.

**Subspecies and Distribution.**

*T. m. brachyurus* Todd, 1927 - W Colombia in W Andes (except at R San Juan headwaters) and W slope of C range, in W & C Antioquia, Quindío, Valle and W Cauca.

*T. m. selvae* Meyer de Schauensee, 1950 - W slope of W Andes at headwaters of R San Juan (in Risaralda and Caldas).

*T. m. multistriatus* Lafresnaye, 1844 - E slope of C Andes and W slope of E & S ranges, in Santander, E Antioquia, E Caldas, W Cundinamarca, E Tolima, Huila and E Nariño.

*T. m. oecotonophilus* Borrero & Hernández, 1958 - extreme W Venezuela (Sierra de Perijá) and NC Colombia (W slope of E Andes in Norte de Santander and Boyacá).

**Descriptive notes.** 15-16.5 cm; 21-23 g. Crested; yellowish iris. Male is barred black and white throughout, including crown, except for streaked area from nape to throat. Female is very different, with crown, upperparts, wings and tail rufous, crown slightly deeper and separated from back by narrow band of black-streaked white or pale reddish-brown, head side and throat streaked black and white, underparts barred black and white, tinged reddish-brown on posterior flanks. Female differs from *T. tenuipunctatus* in proportionately wider white bars below that tend more often to be faintly washed with rufous. Subadult male

is like adult, but tinged yellowish-brown on body and flight-feathers; this plumage possibly retained for some time (museum specimens). Race *brachyurus* has shorter tail than nominate, white bars below broader; *selvae* resembles last, but wider black bars below; *oecotonophilus* is like previous, but tail noticeably longer. **Voice.** Loudsong a rapidly accelerating series of 16-20 nasal notes, pitch obviously falling towards end, terminating in unaccented, slightly slurred note.

**Habitat.** Understorey to canopy of deciduous forest, second-growth scrub, and foothill and montane evergreen forest, generally at 900-2200 m; locally down to 250 m on Pacific slope in Colombia. Mainly in thickets and shrubby borders at forest edge, often venturing into semi-open and cultivated areas, gardens, orchards and parks with thickets, hedgerows and trees. Within its limited range, generally replaces *T. doliatus* at higher elevations.

**Food and Feeding.** Little known. Assumed to feed mostly on various insects and arthropods; stomach contents included seeds of a pomegranate (*Punica granatum*). Few precise data on foraging behaviour; said to be similar to that of *T. doliatus*.

**Breeding.** Evidence of breeding in Mar-Jun in Colombia. Nest undescribed. Eggs reported as whitish, thickly spotted and streaked with red-brown at larger end.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Although occupying a fairly small range, this species is considered fairly common. Its preference for edge and second-growth habitats renders it of low sensitivity to environmental disturbance.

**Bibliography.** Borrero & Hernández (1958), Borrero & Olivares (1955), Cory & Hellmayr (1924), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee (1964), Oates & Reid (1903), Ridgely & Tudor (1994), Ridgely (1911), Salaman, Donegan & Cuervo (2002), Schönwetter & Meise (1967), Selater & Salvin (1879), Stotz *et al.* (1996).

## 20. Lined Antshrike

### *Thamnophilus tenuipunctatus*

**French:** Batara vermiculé **German:** Feinstreifen-Ameisenwürger **Spanish:** Batará Vermiculado

**Taxonomy.** *Thamnophilus tenuipunctatus* [sic] Lafresnaye, 1853. "Anolaima" (location uncertain, possibly in Norte de Santander rather than in Cundinamarca), Colombia.

Has been considered conspecific with *T. palliatus*, but they have adjoining ranges with no apparent barriers and no evidence of intergradation. Both belong to the "*T. doliatus* group", which also includes *T. zarumae*, *T. multistriatus*, *T. torquatus* and *T. ruficapillus*. Plumage variation between *tenuifasciatus* and *berlepschi* may prove to be clinal. Three subspecies recognized.

**Subspecies and Distribution.**

*T. t. tenuipunctatus* Lafresnaye, 1853 - E slope of E Andes in NC Colombia (Norte de Santander, Cundinamarca, Meta).

*T. t. tenuifasciatus* Lawrence, 1867 - E slope in SC Colombia (Putumayo) and Ecuador (Sucumbios S to N Zamora-Chinchipec).

*T. t. berlepschi* Taczanowski, 1884 - E slope in extreme SE Ecuador (S Zamora-Chinchipec) and NE Peru (Amazonas, Cajamarca, San Martín).

**Descriptive notes.** 15-16 cm; 22-23 g. Crested; yellowish iris. Male is black, narrowly barred white, except for black crown, black-streaked white throat. Female has crown, upperparts, wings and tail rufous, crown slightly deeper and separated from back by narrow band of black-streaked white or pale reddish-brown, throat and head side streaked black and white, underparts barred black and white, tinged reddish-brown on posterior flanks. Female differs from *T. multistriatus* in relatively narrower white bars below only rarely washed faintly with rufous. Subadult male resembles adult, but tinged yellowish-brown on body and flight-

feathers. Races *tenuifasciatus* and *berlepschi* have white bars nearly as wide as black bars and more white on forehead, females are paler above than nominate and have white bars below wider. **Voice.** Loudsong an accelerating series of abrupt nasal notes that rises in pitch initially, falls towards end, and terminates in strong, downslurred raspy note. Calls include single short "caa", longer flat whistle, and soft staccato rattle of variable length.

**Habitat.** Understorey and mid-storey of humid evergreen-forest edge; also shrubby, regenerating plantations and clearings, and tangled edges of parks and gardens; 300-2500 m, mostly 500-1700 m.

**Food and Feeding.** Little recorded. Feeds primarily on insects and other arthropods. Forages singly or in pairs, mostly in dense thickets and second-growth edge vegetation, to 10 m above ground; progresses by short hops, with pauses of up to several seconds to scan for prey. Reaches out, up and down to glean prey from all surfaces of leaves, stems, vines and branches, using quick stabbing motions of the bill. Does not routinely join mixed-species flocks.

**Breeding.** Nest undescribed. Eggs reported as reddish-grey with very fine rusty-brown and grey-violet spots all over, although spots denser at blunt end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout its range. This species' ability to utilize a variety of edge and second-growth habitats appears to render it of low sensitivity to environmental disturbance.

**Bibliography.** Cory & Hellmayr (1924), Hilty & Brown (1986), Isler & Whitney (2002), Nehrkorn (1914), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Zimmer (1933a).

## 21. Chestnut-backed Antshrike

### *Thamnophilus palliatus*

**French:** Batara mantelé **German:** Dunkelmantel-Ameisenwürger **Spanish:** Batará Dorsicastaño

**Taxonomy.** *Lanius palliatus* M. H. K. Lichtenstein, 1823, Bahia, Brazil.

Has been considered conspecific with *T. tenuipunctatus*, but the two have adjoining ranges with no apparent barriers and no evidence of intergradation. Both belong to the "*T. doliatus* group", which also includes *T. zarumae*, *T. multistriatus*, *T. torquatus* and *T. ruficapillus*. The validity and distributional limits of the races of present species are in need of re-examination. Four subspecies recognized.

**Subspecies and Distribution.**

*T. p. similis* J. T. Zimmer, 1933 - C Peru (Huánuco, Junín).

*T. p. puncticeps* P. L. Selater, 1890 - SE Peru (Cuzco, Puno), N Bolivia (Beni, La Paz, Cochabamba, Santa Cruz), and Brazil S of R Amazon and W of R Tapajós (extreme SE Amazonas E to extreme SW Pará, S to Rondônia and NW Mato Grosso).

*T. p. palliatus* (M. H. K. Lichtenstein, 1823) - S of R Amazon and E of R Tapajós in N Maranhão, SE Pará and NE Mato Grosso, and coastal NE Brazil (Paraíba S to N Bahia).

*T. p. vestitus* (Lesson, 1830) - coastal E Brazil from S Bahia S to Rio de Janeiro.

**Descriptive notes.** 16-17 cm; 26-28 g. Male has black crown, forehead spotted white, black side of head and nape spotted white; upperparts, wings and tail rufous-brown; throat striped black and white, remaining underparts barred black and white, flanks tinged rufous. Female is like male, but crown deep rufous-brown, light bars on underparts wider. Subadult male resembles adult male, but forehead mixed black and deep reddish-brown, light bars below tinged reddish-brown posteriorly; subadult female is like female, but dark stripes of throat and dark bars of underparts narrower, rear underparts strongly washed yellow-ochre. Races

differ only slightly in intensity and warmth of upperpart colours, relative width of dark and light bars below, and measurements: *similis* resembles nominate; *puncticeps* has upperparts and underparts paler, female nape strongly suffused yellow-ochre; *vestitus* is paler above than previous, darker with broader dark bars below. **Voice.** Loudsong a moderately long (e.g. 20 notes, 2-5 seconds), accelerating series of similar, rapidly delivered, somewhat nasal notes, pitch rising slightly initially, more clearly falling towards end, terminating in longer, firmly accented, downslurred note. Calls include emphatic short nasal note and longer, upward-inflected, squeal.

**Habitat.** Understorey and mid-storey of evergreen-forest borders, taller second growth, regenerating clearings and plantations, and lighter woodland. Andean populations occur primarily from 1000 m to 2200 m, descending to lowlands in C Bolivia, and most often found at forest edges and

clearings with regenerating bamboo. Lowlands in Amazonia, where often in vine-covered trees and shrubs at forest edge and second growth, and in mixed areas of trees and bamboo; in some localities almost restricted to extensive stands of *Guadua* bamboo. Much more of a generalist in coastal E Brazil, and found in shrubby borders of parks and gardens, regenerating plantations and clear-cuts, and at edges of both uncut and degraded evergreen forest, with or without bamboo; to 1000 m, mostly below 300 m.

**Food and Feeding.** Little published. Feeds chiefly on insects, including orthopterans such as grasshoppers (Acrididae), katydids (Tettigoniidae), stick-insects (Phasmatidae) and mantids (Mantidae), beetles (Coleoptera), ants, bees and wasps (Hymenoptera), true bugs (Hemiptera, Homoptera); and lepidopteran larvae; as well as other arthropods, such as spiders. Stomach contents of specimen from Brazil (Pará) included hemipterans, homopterans (Cicadidae), coleopterans (Chrysomelidae, Curculionidae), hymenopterans (Formicidae, Vespoidea, Apoidea) and dipterans (Brachyera). Forages in pairs or individually, in thickets, vine tangles, and in dense canopy foliage of second-growth trees, usually remaining in heavy cover; in much of Amazonia, primarily above 6 m in tangled crowns of bamboo in middle storey, climbing higher to forage in central vine tangles and dense upperstorey foliage of emergent trees (to 15 m). Progresses by short hops, separated by pauses of 1-10 seconds to scan for prey; often hitches from side to side when working upwards through tangles. Reaches out, up and down, or lunges to glean prey from all leaf, stem, vine and branch surfaces with quick stabbing motion of the bill. Often associated, at least loosely, with mixed-species flocks moving through stands of bamboo or tall second growth in its home range. In Andes and SE Brazil, where more a bird of forest edge and scrubby second growth, forages in similar fashion but more often lower, 1-5 m above ground, in dense, shrubby thickets, although sometimes climbs to canopy of mid-storey trees at forest edge; and seldom associated with mixed-species flocks. Recorded as attending swarms of army ants (*Eciton burchelli*) in E Brazil, and seen to supplant *Pyrgilena leuconota* at one such swarm; generally follows ants only through dense understorey thickets at forest edge, then abandons them when ants move into more open areas in interior.

**Breeding.** In Brazil, breeds Oct-Jan in SE and, in NE (Pará), female feeding fledgling in Jun near Belém and nest-building in Nov near mouth of R Tapajós. Nest a small, deep cup loosely constructed from fine, well-interlaced filaments, those of outside much darker, almost black roots or fungus, sometimes decorated with green moss, internal ones yellowish and almost entirely shafts of herbs and fine flower peduncles, sometimes also with "horsehair", the whole attached by rim at 1.5-3 m in horizontal fork among foliage in thicket. Normal clutch 2 eggs, creamy to reddish-white, with irregular purplish, dark brown or reddish-brown spots, blotches and lines most dense at blunt end, almost no markings at pointed end.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Locally fairly common over much of its extensive range. This includes several protected areas, e.g. Tapajós and Tijuca National Parks, Cristalino State Park and Sooretama Biological Reserve, in Brazil, and Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru. Adapted to a variety of habitats, including highly disturbed woodland and second growth, rendering it of low vulnerability.

## 22. Rufous-winged Antshrike

### *Thamnophilus torquatus*

**French:** Batará à ailes rousses **German:** Rostflügel-Ameisenwürger **Spanish:** Batará Alirrufo

**Taxonomy.** *Thamnophilus torquatus* Swainson, 1825, Urupé, Bahia, Brazil.

Belongs to the "*T. dolatus* group", which also includes *T. zarumae*, *T. multistriatus*, *T. temepunctatus*, *T. palliatus* and *T. ruficapillus*. Appears to form a superspecies with last of those, but syntopy is suspected in S of range in Brazil (extreme E Minas Gerais and NW Rio de Janeiro). Monotypic.

**Distribution.** E Brazil (S Pará and S Maranhão E to Pernambuco and S to WC Mato Grosso, Mato Grosso do Sul, São Paulo, W edge of Rio de Janeiro and coastal C Bahia), NE Bolivia (NE Santa Cruz) and NE Paraguay (Canendiyu).

**Descriptive notes.** 14 cm; 18-20 g. Male has black crown, grey side of head and upperparts, cinnamon-rufous wings and wing-coverts; graduated tail black, outer rectrices with complete white bars (appearing as spots from above); throat and underparts whitish, breast barred black. Distinguished from similar *T. ruficapillus* by black crown, paler overall plumage, smaller size. Female differs from male in rufous crown and tail, mottled whitish and grey head side, pale cinnamon-rufous upperparts, buff-tinged underparts, especially breast, flanks and crissum, breast unbarred or sometimes with faded band of dusky bars.

**Voice.** Loudsong a moderately long (e.g. 16 notes, 3-4 seconds) accelerating series of nasal notes, first one long and drawn out, followed by increasingly shorter notes, ending in longer downslurred note; similar to loudsong of *T. ruficapillus*, but immediately distinguished from that of *T. palliatus* by long initial note. Calls include querulous upslurred whistle, also a nasal note that becomes harsh, and a growl.

**Habitat.** Understorey of *cerrado* and adjacent semi-deciduous woodland, riparian thickets and brushy second growth; up to 1750 m, mostly below 1000 m. Often in regenerating pastures and plantations where shrubs interlacing and canopy height exceeds 2 m.

**Food and Feeding.** Little published. Feeds on variety of insects, including larval lepidopterans, grasshoppers (Acrididae), beetles (Coleoptera, including Curculionidae), ants (Formicidae) and other Hymenoptera, and larval Neuroptera; also other arthropods, such as spiders. Pairs or individuals forage mostly 0-2 m above ground, sometimes up to treetops, progressing by short hops, with pauses of 2-15 seconds to scan for prey. Perch-gleans prey from all sides of green leaves, stems and branches, with quick stabbing motions of the bill; sometimes makes short, jumping, upward-directed sallies to glean items from undersides of overhanging vegetation; also frequently drops to ground to pounce on prey spotted from above. Usually alone, but sometimes associated with mixed-species groups of other insectivores, including *Formicivora rufa* and White-eared Puffbird (*Nystalus chacuru*), Chequered Woodpecker (*Picoides mixtus*), Narrow-billed Woodcreeper (*Lepidocolaptes angustirostris*), Campo Flycatcher (*Suiriri suiriri affinis*) and Plain-crested Elaenia (*Elaenia cristata*).

**Breeding.** Nests found in Apr-Jun in E Brazil (13 in Alagoas, 1 in Bahia; details previously unpublished). Nest built by both sexes, cup-shaped, walls solidly woven from fine grass stalks, rootlets and black *Marasmius* fibres, sometimes with inflorescences, bits of moss and bark fibres (occasionally also fragments of wool or twine, even small balls of cotton) incorporated; for 6 nests average external diameter 9 cm, height 6-5 cm, internal diameter 7-5 cm, depth 5 cm, two weighed 5 g, one 10 g; suspended by rather broad strips of vegetation (e.g. bark) 2-5-3 cm long, 0-7-1-5 m above ground in fork of bush, often beside forest trail; one pair spent 13 days in building nest, then abandoned it and started another nest 20 m away. Normal clutch 2 eggs, one record of 3, white, numerous violaceous and brown spots and streaks (and a few russet and dark brown lines) over entire surface, more concentrated at blunt end (sometimes forming vague wreath); incubation by both sexes, at one nest male incubated for 70% and female for 30% of time, at another male sat continuously for 100 minutes in morning, incubation period at two nests 15 days; hatching naked, skin dark violet; chicks fed at same rate by both parents, with insects (e.g. adult and larval lepidopterans, small beetles), nestling period at one nest 10 days.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common, but somewhat locally distributed. This species' preferred habitats of *cerrado* and gallery forest are patchily distributed, and are among the most threatened in South America. It does, however, occur in several large protected areas, including Chapada dos Guimarães, Chapada Diamantina and Serra da Canastra National Parks, in Brazil, and Noel Kempff Mercado National Park, in Bolivia, and it appears capable of adapting to second-growth habitats, thus rendering it less sensitive to disturbance.

**Bibliography.** Bates *et al.* (1992), Capper, Clay, Madroño & Mazar Barnett (2001), Capper, Clay, Madroño, Mazar Barnett, Burfield *et al.* (2001), Coelho (1987), Cory & Hellmayr (1924), Euler (1900), Isler & Whitney (2002), Motta-Júnior (1990), Motta-Júnior & Vasconcello (1996), do Nascimento *et al.* (2000), Naumburg (1930), Novaes (1992), Parker (2003a), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Sick (1955, 1993, 1997), da Silva & Oniki (1988), Stotz *et al.* (1996), Studer (2002), Zimmer (2003a).

## 23. Rufous-capped Antshrike

### *Thamnophilus ruficapillus*

**French:** Batara à tête rousse **German:** Rostscheitel-Ameisenwürger **Spanish:** Batará Pardo  
**Other common names:** Marcapata Antshrike (*marcapatae*)

**Taxonomy.** *Thamnophilus ruficapillus* Vieillot, 1816, no locality = Corrientes, Argentina. Belongs to the “*T. doliatus* group”, which also includes *T. zarumae*, *T. multistriatus*, *T. tenuipunctatus*, *T. palliatus* and *T. torquatus*. Appears to form a superspecies with last of those, but syntopy is suspected in S of range in Brazil (extreme E Minas Gerais and NW Rio de Janeiro). Five subspecies recognized.

#### Subspecies and Distribution.

*T. r. jaczewskii* Domaniewski, 1925 - N Peru (Cajamarca, Amazonas S of R Maraón, San Martín).  
*T. r. marcapatae* Hellmayr, 1912 - S Peru (Cuzco, Puno).  
*T. r. subfasciatus* P. L. Selater & Salvin, 1876 - NW Bolivia (La Paz, W Cochabamba).  
*T. r. cochabambae* (Chapman, 1921) - E Cochabamba and SW Santa Cruz S to NW Argentina (Jujuy, Salta, Tucumán).  
*T. r. ruficapillus* Vieillot, 1816 - E Paraguay and SE Brazil (S from E Minas Gerais and Espírito Santo) S to NE Argentina (Misiones, Corrientes, Entre Ríos, NE Buenos Aires) and Uruguay.

**Descriptive notes.** 15-17 cm; 21-24 g. Male nominate race has crown chestnut, side of head and throat pale buffy brown, mottled and faintly barred dusky brown; upperparts dark brown, wings rufous-brown; graduated tail brownish-black, tips and inner webs of outer feathers barred white; underparts white, tinged buff, narrow irregular black bars across breast and sides, buff flanks and crissum tinged olive. Distinguished from similar *T. torquatus* by chestnut crown, somewhat darker plumage, larger size. Female differs from male in cinnamon-brown crown, rufous-brown tail without white markings, only hint of barring across

breast. Race *jaczewskii* male has head side and throat grey and faintly barred, upperparts olive-tinged dark grey, wings chestnut, underparts barred white and black, flanks tinged olive, female olivaceous above, bright buff below, belly paler; *marcapatae* is similar to previous, but upperparts, side of head and flanks dark grey, throat more distinctly barred, black bars below heavier, female dark olive-grey above, strong reddish yellow-brown below with throat and belly paler, admixed grey on flanks; *subfasciatus* male very similar to *jaczewskii*, female resembles *marcapatae* but slightly paler, *cochabambae* male has head side and throat buffy white, edged and streaked light grey, upperparts mid-grey, tail more barred, buffy breast and sides barred black, belly buffish-white, flanks and crissum mixed light buff and grey, female is olivaceous above, whitish below, with buff tinge on breast and sides, olivaceous-buff tinge on flanks and crissum. **Voice.** Loudsong a moderately long (e.g. 13 notes, 3-3 seconds, nominate race) accelerating series of nasal notes, initial note long and drawn out, followed by increasingly shorter notes, ending in longer downslurred note, similar to that of *T. torquatus*; pace and number of notes may vary regionally (differences remain to be analysed). Calls include upslurred whistle, also loud raspy “chirr” upslurred at end, likened to sound of canvas being torn; calls may differ regionally.

**Habitat.** Understorey of montane evergreen forest-edge in Andes, also secondary scrub, regenerating clearings, and isolated thickets and patches of woodland in otherwise open country. At 1750-3050 m in Andes (*jaczewskii*, *marcapatae*, *subfasciatus*); *cochabambae* at 600-2700 m in Bolivia, descending lower in Argentina; and nominate race from sea-level to 2400 m, at higher elevations in N, lower in S. Found in the densest forest understorey in N Peru; farther S in Andes inhabits semi-humid forest and second growth, but also occurs in patches of dense shrubs and trees bordering watercourses in predominantly open areas of intermontane valleys. In N Argentina and extreme SE Brazil, at lower elevations, commonly in isolated thickets of shrubby vegetation and small trees (canopy less than 5 m) growing on slight rises in middle of grassy marshes; also in second growth, scrub, hedgerows, brush piles; not inside forest. Farther N, on mountain tops of SE Brazil, found in impenetrable thickets on windswept brushy grassland.

**Food and Feeding.** Little published. Feeds on various insects and other arthropods, including beetles (Curculionidae, Chrysomelidae), moths (Noctuidae), ants (Formicidae) and flies (Diptera). Apparently feeds not uncommonly on fruit (e.g. *Trema*) and mistletoe (*Rapanea*) in SE Brazil. Forages in pairs or singly, mostly 0-2 m above ground, occasionally to 7 m, progressing slowly by short hops separated by pauses of, on average, 2-4 seconds, frequently longer. Perch-gleans from all live leaf, stem and branch surfaces with quick stabbing motion of the bill; sometimes makes short, jumping, upward-directed sallies to take prey from undersides of overhanging vegetation; frequently drops from a low perch to pounce on prey on ground. In SE Brazil, often inspects and probes in bases of bromeliads and large *Cattleya* orchids, the capture of all but small items being followed by deliberate wiping of the bill on a branch.

**Breeding.** Oct-Dec (once in Feb) in Argentina and Oct-Nov in Brazil. Nest a cup with external diameter 10 cm, internal diameter 6 cm, height 6 cm, depth 5 cm, composed of irregular strips of straw, grasses and short, wrinkled fragments of club-rush (*Scirpus*), lined with very fine straw, rootlets and some horsehair, with some strands projecting from the bulk of the nest up to 11 cm, the whole decorated with bits of wool and generally straw-yellow in colour, suspended by rim from horizontal fork or parallel branches, to which bound by spider webs, 1-2 m above ground in bush or sapling (most often *Scutia* or *Celtis*); an unusual nest in Brazil was a deep cup (outside height 9 cm, inside depth 6 cm) attached to a vertical fork in such a way that the rim was free and the two branches held the entire length of the side wall, approximately like a flag on a pole. Normal clutch (known only for nominate race) 3 eggs, sometimes 2, whitish, with violet-brown and purplish-grey spots and sometimes lines most dense around large end. Brood parasitism by Shiny Cowbirds (*Molothrus bonariensis*) recorded in Argentina.

**Movements.** Most races presumed resident, but at least some individuals of nominate race may move N from S extremity of range in austral winter.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its highly disjunct range. Occurs in several protected areas, including Itatiaia, Serra dos Órgãos and Aparados da Serra National Parks, in Brazil, and El Rey and Calilegua National Parks, Ingeniero Otamendi Reserve and Costanera Sur Ecological Reserve, in Argentina. Ability of most races to utilize shrubby thickets, forest edge and other forms of second growth renders them of low sensitivity to distur-

bance. In N Peru, race *jaczewskii* is rare and poorly known, and may possibly be threatened by forest destruction.

**Bibliography.** dos Anjos (2001a), Barrows (1884), Belton (1985), Bencke & Kindel (1999), Cory & Hellmayr (1924), Cuello & Gerzenstein (1962), Darrieu *et al.* (1988), Dumford (1877, 1878), Euler (1867, 1868), Ferreira de Vasconcelos & Melo-Júnior (2001), Fjeldså & Krahbe (1990), Fjeldså & Majer (1996), Fraga & Narosky (1985), Hartert & Venturi (1909), Ihering (1900), Isler & Whitney (2002), Lowen, Clay *et al.* (1997), Narosky & Yzurieta (1993), Parker (2003a), Pereyra (1938), Pineschi (1990), Ridgely & Tudor (1994), Schmitt *et al.* (1997), Schönwetter & Meise (1967), Schulenberg (1983), Schulenberg & Awbrey (1997b), Selater & Hudson (1888), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Voss & Sander (1980), Wetmore (1926), Zimmer, J.T. (1933b), Zimmer, K.J. (2003a), Zotta (1936).

## 24. Black-hooded Antshrike

### *Thamnophilus bridgesi*

**French:** Batara capucin **German:** Kapuzenameisenwürger **Spanish:** Batará Negruzco  
**Other common names:** Bridges's Antshrike

**Taxonomy.** *Thamnophilus bridgesi* P. L. Selater, 1856, David, Chiriqui, Panama. Relationships uncertain. Monotypic.

**Distribution.** Pacific slope in Costa Rica (except extreme NW) and W Panama (Chiriqui, S Veraguas, Los Santos).

**Descriptive notes.** 16 cm; 26-27 g. Male is black, except for white interscapular patch, small white dots on wing-coverts, white tips on outer tail feathers, dark grey posterior underparts. Female has forehead, crown and side of head blackish-grey, narrowly streaked white, upperparts and wings very dark greyish-brown, anterior scapulars edged white, wing-coverts spotted white, tail blackish-brown, outer feathers spotted white; underparts olive, darker anteriorly, streaked white on throat, breast and belly. Juvenile is like female but browner, with larger spots, especially on wing-coverts; subadult male resembles adult but more brownish, and anterior underparts streaked white. **Voice.** Loudsong a moderately long (e.g. 18 notes, 2-5 seconds) series of abrupt, dry notes, accelerating and rising in pitch slightly at beginning and then constant in pitch and pace, ending with longer, downslurred, emphatic note; also a loud sharp note repeated 5-35 times at rate of c. 5 notes per second. Call an extended, complaining note, usually repeated 2-3 times.

**Habitat.** Understorey and mid-storey of evergreen forest, transitional semi-deciduous forest, taller second-growth woodland, and mangroves, from sea-level to 1100 m. In humid evergreen forest generally confined to shrubby thickets and vine tangles at borders (and adjacent second growth) and in light-gaps within the forest. In transitional and gallery forests frequently occupies interior, particularly in micro-habitats with abundant vines. Near the coast, also found in seasonally dry stands of mangroves where shrubby thickets present in understorey.

**Food and Feeding.** Little published. Feeds on variety of insects, particularly orthopterans such as crickets (Gryllidae), grasshoppers and katydids (Ensifera), also cockroaches (Blattodea), mantids (Mantidae), stick-insects (Phasmatidae), true bugs (Hemiptera, Homoptera), beetles (Coleoptera), and larvae of Lepidoptera; also other arthropods, such as spiders. Pairs or individuals forage mostly in vine tangles, from ground level to 15 m, moving even more sluggishly than most antshrikes, with short hops separated by lengthy pauses of up to 30 seconds to scan for prey. Reaches out, up or down, or lunges to glean prey from all leaf, stem, vine and branch surfaces with quick stabbing motions of the bill; routinely probes suspended dead leaves, often sitting astride larger leaves and probing and tearing vigorously with the bill. In drier forest habitats, also commonly forages on ground, where it probes in the litter, turning and tossing leaves with its bill, frequently jumping up to a low perch less than 1 m above ground to scan, before dropping back down. Often associated with mixed-species flocks. Occasionally follows army ants (*Eciton*) to feed on flushed arthropod prey.

**Breeding.** Feb-Sept in Costa Rica. Nest a roomy open cup of fine, dark rootlets and other filamentous fibres, bound with cobweb to its supports, and often decorated with bits of green moss on outside, suspended by rim from horizontal fork 0.6-3.6 m above ground among foliage at end of slender branch in dense vegetation. Normal clutch 2 eggs, dull white, with wreath of bright brown and pale lilac blotches and spots around large end, a few speckles elsewhere; incubation shared by both parents during day, by female at night, period 14-15 days; chick hatches without down; both parents feed nestlings.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in South Central American Pacific Slope EBA. Locally common within its tiny range. Occurs in a number of parks and reserves in Costa Rica, e.g. Carara Biological Reserve, Corcovado and Manuel Antonio National Parks, Golfo Dulce Forest Reserve, Wilson Botanical Garden. Although seemingly capable of persisting in disturbed habitats, it has gradually disappeared from much of its now deforested former range in Panama. Current parks and reserves in Costa Rica should, with continued protection, support an adequate population of this species.

**Bibliography.** Aldrich & Bole (1937), Carriker (1910), Cherrie (1893, 1895), Cory & Hellmayr (1924), Foster (1975), Isler & Whitney (2002), Ridgely & Gwynne (1989), Ridgway (1911), Schönwetter & Meise (1967), Skutch (1969c), Slud (1964), Stattersfield *et al.* (1998), Stiles & Skutch (1989), Stotz *et al.* (1996), Swartz (2001), Wetmore (1972), Willis (1984d), Zimmer (2003a).

## 25. Black Antshrike

### *Thamnophilus nigriceps*

**French:** Batara noir **German:** Nördlicher Schwarzameisenwürger **Spanish:** Batará Negro

**Taxonomy.** *Thamnophilus nigriceps* P. L. Selater, 1869, “Bogotá” trade skin; probably = vicinity of Barranquilla, Atlántico, Colombia.

Forms a superspecies with *T. praecox*. Described race *magdalenae* (N Colombia) appears to represent the end point of a cline. Monotypic.

**Distribution.** E Panama (E Panamá, Darién) and N Colombia (N Chocó E to W La Guajira, and S in Magdalena Valley to Tolima).

**Descriptive notes.** 16 cm; 23–24 g. Male is entirely black, except for dark grey flanks and white underwing-coverts and edges of flight-feathers below. Female has upperparts, wings and tail rufous-brown, head, throat and upper breast blackish-grey, becoming grey on lower breast and belly, buff on posterior underparts; head to belly with buff-white streaks varying in width individually as well as regionally, proportion of females with streaking narrow increases clinally from N to S, reaching extreme in S Magdalena Valley (“*magdalenae*”, streaks restricted to feather shafts). Subadult male is like adult female but with pale edgings on

wing-coverts, black barring on posterior underparts; subadult female has broader streaking on anterior underparts. **Voice.** Loudsong a moderately long (e.g. 12 notes, 2–3 seconds), slightly accelerating, evenly pitched series of somewhat musical yet emphatic notes; also delivers similar notes in a more rapid, uncountable series introduced by firmly accented note. Calls include hollow, nasal note sometimes repeated, and nasal growl.

**Habitat.** Shrubby understorey and regenerating clearings of humid evergreen forest, less often lighter woodland and taller second growth, to 600 m. Particularly favours dense, viny, thorny or *Heliconia* thickets, both at forest edge and in interior.

**Food and Feeding.** Little recorded. Assumed to feed on insects and arthropods. Pairs or individuals forage in shrubby, viny thickets, mainly 1–2 m above ground but sometimes to 7 m, progressing by short hops, with pauses of up to several seconds to scan for prey. Jerks tail upwards when alarmed.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Poorly known. Occurs in Los Katios and Tayrona National Parks, in Colombia. Apparently locally fairly common, but the small geographic range of this species justifies better clarification of its true status and conservation needs. Perhaps better categorized as Data-deficient.

**Bibliography.** Cory & Hellmayr (1924), Darlington (1931), Dugand (1940), Griscom (1927b), Hilty & Brown (1986), Isler & Whitney (2002), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Rodríguez (1982), Stotz *et al.* (1996), Todd & Carriker (1922b), Wetmore (1972), Willis (1988b).

## 26. Cocha Antshrike

### *Thamnophilus praecox*

**French:** Batara du Cocha **German:** Südlicher Schwarzzeisenwürger **Spanish:** Batará de Cocha

**Taxonomy.** *Thamnophilus praecox* J. T. Zimmer, 1937, mouth of Lagarto Cocha, Napo, Ecuador. Forms a superspecies with *T. nigricaps*. Monotypic.

**Distribution.** NE Ecuador locally along R Napo and its tributaries (in E Napo and E Sucumbios).

**Descriptive notes.** 16 cm. Male is entirely black except for white underwing-coverts. Female has head, throat and upper breast black, throat sometimes faintly streaked white along shafts, remaining plumage cinnamon-rufous, underparts slightly paler. **Voice.** Loudsong a rapidly delivered (too fast to count), moderately long (e.g. 18 notes, 2–5 seconds) series of deep, hollow, although somewhat liquid notes, constant in pitch, intensity and pace; also delivers similar notes in a more rapid series in which first note lengthened and firmly accented. Call is mellow and often given in doublets.

**Habitat.** Understorey of lowland, seasonally flooded, evergreen forest, at 200–250 m. Apparently confined to black-water drainages, where it inhabits dense shrubby streamside thickets and tangles, often containing *Cecropia* and *Heliconia*.

**Food and Feeding.** Little recorded. Assumed to feed primarily on insects and other arthropods. Individuals or pairs forage low in dense thickets along black-water streams, progressing by short hops, with pauses of up to several seconds to scan for prey. One individual was seen to pick a large caterpillar off a leaf and take this to the ground to beat it, before swallowing.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Upper Amazon-Napo Lowlands EBA. Long known only from a single female specimen, this species was rediscovered in 1990 at Imuya Cocha, near the type locality. Subsequently found to be fairly common in that area, with smaller numbers present S of R Aguarico at Zaneudo Cocha and near R Pacuyacu, at La Selva and Sacha Lodges, and S of R Napo near Pompeya. Seemingly a low-density species confined to black-water drainages, but with no immediate threats. Habitat degradation resulting from expansion of petroleum exploration in the Napo basin could represent a future threat.

**Bibliography.** Behrstock (2003), Budney (2003), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Isler & Whitney (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1937).

## 27. Blackish-grey Antshrike

### *Thamnophilus nigrocinereus*

**French.** Batara demi-deuil **German.** Schwarzgrauer Ameisenwürger **Spanish.** Batará Ceniciento

**Other common names:** Grey Antshrike

**Taxonomy.** *Thamnophilus nigrocinereus* P. L. Sclater, 1855, Rio Tocantins, Pará, Brazil. Forms a superspecies with *T. cryptoleucus* and formerly considered conspecific. Races distinctive in plumage; furthermore, differences among them in calls, and also the possibility that Amazonian races may meet each other without intergradation, require study. Five subspecies currently recognized.

**Subspecies and Distribution.**

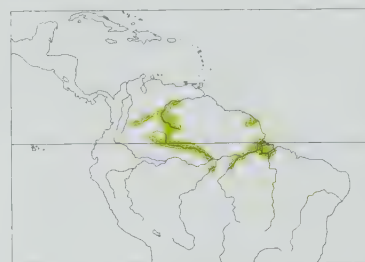

*T. n. cinereoniger* Pelzeln, 1868 - NE Colombia, SW Venezuela and NW Amazonian Brazil (drainages of, respectively, R Meta, upper R Orinoco, and lower R Uaupés and R Negro).

*T. n. tschudii* Pelzeln, 1868 - WC Brazil (E Amazonas along lower R Madeira).

*T. n. huberi* Sneath, 1907 - EC Brazil (W Pará along lower R Tapajós).

*T. n. nigrocinereus* P. L. Sclater, 1855 - E Brazil from near mouth of R Tapajós along lower R Amazon and surrounding rivers E to Amapá and islands in estuary.

*T. n. kulczynskii* (Domaniewski & Stolzmann, 1922) - E French Guiana and adjacent Brazil (extreme N Amapá).

**Descriptive notes.** 16–17 cm; 28–32 g. Male nominate race is blackish-grey, blackest on head, throat and back, palest on rump and belly, tinged brownish on wings; interscapular patch white, scapulars, wing-coverts and flight-feathers edged white, tail tipped white. Female has crown and side of head blackish-grey, upperparts dark grey with reddish-brown tinge, wings and tail brown, underparts reddish-brown, darkest across breast. Race *huberi* differs from nominate in being greyer except on crown, crissum tipped white, female in having back and tail rufous-brown, underparts cinnamon-rufous; *tschudii* has black upperparts,

blackish underparts, female is chestnut-brown above, throat sooty brownish-black; *cinereoniger* paler overall, with grey upperparts, mixed black on centre of back, grey below darker anteriorly, palest on belly, crissum tipped white, female with crown and side of head grey, upperparts dark rufous-brown, wing-coverts edged pale rufous, underparts and underwing-coverts orange-rufous, subadult male like female except wing-coverts narrowly edged white and underparts mixed grey and cinnamon-rufous; *kulczynskii* female has head blackish, upperparts olive-brown, posterior underparts greyish. **Voice.** Loudsong of male a strongly accelerating, slowly delivered (e.g. 8 notes in 2–4 seconds) series of low-pitched, mellow, punchy notes, either slightly descending (e.g. nominate race) or nearly even in pitch (e.g. *cinereoniger*); female loudsong usually begins at higher pitch but descends more noticeably. Call of *cinereoniger* nasal and muffled, and often doubled, nominate race similar but rising; also a trill or rattle introduced by one or two longer emphatic notes.

**Habitat.** Understorey and mid-storey of seasonally flooded evergreen forest, gallery forest, and scrubby savanna woodland; locally in shrubby borders of humid upland forest, and in mangroves. In most of Amazonia, lives on river islands and borders in dense understorey of seasonally flooded *várzea* and *igapó* forest, in tall thickets at river edge, and at nearby edges of clearings. On large islands at mouth of Amazon (*nigrocinereus*) typically found in dense forest stands on high ground surrounded by seasonally flooded *campos*. In Colombia and Venezuela (*cinereoniger*) most common in seasonally flooded, stunted (4–10 m), dense savanna woodland on white-sand soils; also in gallery forest. In French Guiana (*kulczynskii*) a characteristic bird of young and middle-stage stands of coastal mangroves, with highest densities in mixed stands of white mangrove (*Avicennia germinans*) and red mangrove (*Rhizophora*), but also occurs in densely vegetated river edges away from coast.

**Food and Feeding.** Feeds on variety of insects and other arthropods. Most available data are for race *cinereoniger*: on river islands in R Negro observed to take crickets (Gryllidae), cockroaches (Blattodea), and moths and caterpillars (Lepidoptera); stomach contents included a 7-cm stick-insect (Phasmatodea), true bugs (Hemiptera), beetles (Coleoptera) and hymenopterans. Pairs or individuals (of *cinereoniger*) forage at 0–3 m, but mostly within 0–3 m of ground, perching on low branches, stems or aerial roots, progressing by hops and short flights, with intervening pauses of 1–10 seconds to scan for prey. Clings to perches with feet, reaching down to seize prey from leaf litter; frequently drops to ground to pounce on prey, before jumping back up to a low perch; also commonly makes short, upward-directed jumps to glean prey from undersides of overhanging green leaves. Sometimes loosely associated with understorey mixed-species flocks. In French Guiana, race *kulczynskii* forages in middle stratum (3–10 m up) of mangrove forest, rarely in canopy, but sometimes seeks insects on wet or inundated ground by hanging on to roots of mangroves and large ferns.

**Breeding.** Little recorded; breeding reported in Mar on upper R Orinoco, Venezuela; other data available only from French Guiana (*kulczynskii*), to which following details refer. Five nests recorded, all in Aug–Sept. Nest built by both sexes, a deep cup primarily of woven fibres of the slender liana *Rhabadenia biflora* and other dried herbaceous material, additionally bound with webbing from spider egg sacs, attached by rim 1–2 m above ground in horizontal peripheral fork of a small shrub, most commonly grey mangrove (*Laguncularia racemosa*). Clutch 2 eggs, creamy white to reddish-white with large, angular violet-brown spots, marks more extended and more abundant at larger end; no information on incubation and nesting periods. All five nests lost to predation before young fledged; arboreal snakes thought to be main predators.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common, including in a number of parks and biological reserves. Fairly common in, for example, Jau and Tapajós National Parks and Rio Negro State Park, in Brazil, and Alto Orinoco-Casiquiare Biosphere Reserve and Yapacana National Park, in Venezuela, as well as in numerous indigenous reserved zones in SE Colombia, SW Venezuela and N Brazil. Some Amazonian forms appear to tolerate the proximity of humans and inhabit shrubby surrounding clearings on river islands.

**Bibliography.** Cory & Hellmayr (1924), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Meyer de Schauensee & Phelps (1978), Oren & Parker (1997), Reynaud (1998), Ridgely & Tudor (1994), Sick (1993), Sneath (1913), Stotz *et al.* (1996), Tostain (1986a, 1986b), Tostain *et al.* (1992), Zimmer, J.T. (1933a), Zimmer, K.J. (1997, 2003a), Zimmer, K.J. & Hilty (1997).

## 28. Castelnau's Antshrike

### *Thamnophilus cryptoleucus*

**French:** Batare de Castelnau **German:** Flussufer-Ameisenwürger **Spanish:** Batará de Castelnau

**Taxonomy.** *Myrmelastes cryptoleucus* Menegaux and Hellmayr, 1906, Pebas, Loreto, Peru. Forms a superspecies with *T. nigrocinereus* and formerly considered conspecific. Monotypic. **Distribution.** NE Ecuador and N Peru (locally along R Napo, R Marañón, R Santiago and R Ucayali) E along R Amazon in W Brazil (E to vicinity of mouth of R Negro).

**Descriptive notes.** 16-17 cm; 30-35 g. Male is black, with white interscapular patch, white tips or edges on scapulars, wing-coverts and bend of wing, sometimes very small white tips on outer rectrices, dark grey flanks and posterior underparts, white underwing-coverts. Female lacks visible white wing edgings. Subadult resembles female but browner. **Voice.** Rapidly accelerating series of evenly pitched, emphatic, complex notes (e.g. 14 notes, 2-2 seconds) with complaining quality; individuals often vary the number of notes in successive songs. Calls include loud, abrupt, nasal note; same note also introduces a trill or rattle

of highly variable length; other calls include longer, somewhat muffled, complaining note and a growl.

**Habitat.** Understorey and mid-storey of seasonally flooded evergreen forest and tall second-growth woodland on islands in white-water rivers. Chiefly on middle-aged and older islands, but also found in riverbank forest wherever the force of the current maintains an appropriate level of vegetation succession. Inhabits dense undergrowth and mid-storey of *Cecropia* forest. Also found at edge of older forest in understorey composed of saplings mixed with cane and *Heliconia*.

**Food and Feeding.** Little published. Feeds on various insects and other arthropods; visual observations have identified large and small caterpillars. Pairs or individuals forage primarily 1-3 m above ground, occasionally to 6 m, rarely to 9 m, in *Cecropia*-dominated woodland, progressing slowly by short hops separated by scanning pauses of up to several seconds. Reaches out, up and down, or lunges to glean prey from all sides of green leaves, stems and branches, occasionally from dead-leaf clusters; employs quick stabbing motions of the bill; also regularly makes short sallies to pick prey from undersides of overhanging vegetation. Seldom associates with mixed-species flocks.

**Breeding.** Nothing known.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its narrow, linear distribution. Total population size, like that of most obligate river-island birds, is probably relatively small; further, because of the dynamic nature of river-island habitats, continued existence of these birds is dependent on perpetual formation of new islands. Few existing parks or reserves include extensive river-island habitats within their boundaries, leaving habitat specialists such as this antshrike vulnerable to any major changes in water flow in the Amazon and its major tributaries; such changes could arise from damming, or from increased flooding and erosion resulting from deforestation.

**Bibliography.** Isler & Whitney (2002), Parker (2003a), Remsen & Parker (1983, 1984), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, G.H. (1985, 1990), Russell & Lamm (1978), Sick (1993), Stotz *et al.* (1996), Zimmer, J.T. (1933a), Zimmer, K.J. (1997).

## 29. White-shouldered Antshrike

### *Thamnophilus aethiops*

**French:** Batare à épaulettes blanches **Spanish:** Batará Hombroblanco  
**German:** Perlshulter-Ameisenwürger

**Taxonomy.** *Thamnophilus aethiops* P. L. Slater, 1858, Rio Napo, Napo, Ecuador.

Forms a superspecies with *T. unicolor*. A number of diagnosable races, geographically separated by Amazonian rivers, may be full species; molecular and other analyses, including of vocalizations, as well as investigation of possible intergradation at headwaters of rivers, are needed. Races *juruanus* and *kapouni* appear to intergrade. Ten subspecies recognized.

**Subspecies and Distribution.**

*T. a. wetmorei* Meyer de Schauensee, 1945 - foothill region in SE Colombia (W Meta S to E Cauca and W Putumayo).

*T. a. aethiops* P. L. Slater, 1858 - foothill region in E Ecuador and N Peru (N of R Marañón).

*T. a. polionotus* Pelzeln, 1868 - S Venezuela (Amazonas, SE Bolívar), extreme E Colombia (E Guainía, E Vaupés), and NW Brazil (N Roraima, and R Negro in upper drainage and on W bank of lower stretches S to R Solimões).

*T. a. kapouni* Seilern, 1913 - E Peru (S of R Marañón and R Amazon), extreme W Brazil (SW Amazonas E to R Jurúá) and N Bolivia (Pando S to La Paz and Cochabamba).

*T. a. juruanus* H. von Ihering, 1905 - SW Amazonian Brazil between R Jurúá and R Purus.

*T. a. injunctus* J. T. Zimmer, 1933 - Amazonian Brazil between R Purus and R Madeira.

*T. a. punctuliger* Pelzeln, 1868 - Amazonian Brazil between R Madeira and R Tapajós (S to Rondônia and NW Mato Grosso) and extreme NE Bolivia (NE Santa Cruz).

*T. a. atriceps* Todd, 1927 - Amazonia in S Pará & NE Mato Grosso (between R Tapajós & R Tocantins).

*T. a. incertus* Pelzeln, 1868 - Pará S of R Amazon (E of R Tocantins) and NW Maranhão.

*T. a. distans* Pinto, 1954 - NE Brazil (coastal Pernambuco and Alagoas).

**Descriptive notes.** 15-17 cm; 23-30 g. Male nominate race is black, except for a few small whitish spots on lesser wing-coverts and bend of wing, and blackish-grey posterior underparts. Female is deep reddish-brown. Subadult resembles female, but with pale spots on wing-coverts. Races differ mainly in overall darkness, most paler than nominate, degree of spotting on wing-coverts, contrast below: *wetmorei* is blackish-grey above, small white spots also on greater and median wing-coverts, uniform grey below; *polionotus* differs from last in slightly less blackish upperparts, small white spots on outer tail, female with rufous crown, yellowish red-brown above, reddish yellow-brown underparts becoming

ing paler posteriorly; *kapouni* is slightly darker than last, no spots on greater coverts, breast slightly darker than belly; *juruanus* is less dark above than previous; *injunctus* has darker back than last, also white spots on greater and median coverts; *punctuliger* differs from last in slightly paler back, small white tips on outer rectrices, white interscapular patch, breast darker than belly, both sexes with pale spots on wing-coverts; *atriceps* also has breast darker than belly, spots only on lesser coverts; *incertus* is palest, crown grey, no spots on greater coverts, light grey below, breast slightly darker, female mostly pale rufous with white belly; *distans* is

darker than previous, white spots on greater and median wing-coverts. **Voice.** Male loudsong a short and slowly paced (e.g. 6 notes, 2-2 seconds) series of low-pitched, complaining notes delivered at steady pace and even pitch and intensity; female song similar but typically slightly higher-pitched, sounding more complaining. Common call abrupt throaty "cuck", often repeated in long sequences, and sometimes interspersed with longer calls; longer calls include caws (sometimes long and downslurred), nasal twangs, long and short growls, and single notes of loudsong. Possibility of geographical differences in vocalizations requires investigation.

**Habitat.** Understorey of lowland evergreen forest, mostly below 700 m, occasionally to 1150 m; to c. 2000 m in Andes (*aethiops*, *wetmorei*). Typically in low tangled vegetation at overgrown light-gaps (especially old treefall sites) and along streams within upland and transitional forest, often in thick stands of *Heliconia*. Locally, e.g. Alta Floresta region (Mato Grosso, Brazil), associated with dense stands of bamboo (*Guadua*) within *terra firme* or transitional forest. Also sometimes found in thick undergrowth at edge of extensive primary forest.

**Food and Feeding.** Little published. Feeds on variety of insects and arthropods. Pairs or individuals forage mostly 1-5 m above ground in dense understorey thickets, progressing by short hops, with intervening pauses of 1-10 seconds or more to scan for prey, peering in all directions. Often jumps to new perch before reaching out, up or down, or lunging to glean arthropods from surfaces of leaves (mostly undersides), stems, vines and branches with quick stabbing motions of the bill; occasionally makes awkward short sallies, flutters into dead-leaf clusters, or drops to ground to rummage among litter. In most parts of range forages independently, but in E Ecuador (*aethiops*) often accompanies mixed-species flocks that are largely restricted to vine tangles; in Mato Grosso (*atriceps*), routinely forages to heights of 8 m in large stands of bamboo, and often accompanies mixed-species understorey flocks. One published record of pair in Brazil following an army-ant (*Eciton burchelli*) swarm as it passed through a treefall zone: the birds clung to low, inclined or vertical saplings above swarm, then abandoned it before the ants entered the open forest understorey.

**Breeding.** Little recorded. In Brazil, single nests found in Oct, Nov and Feb (*incertus*), Jul (*punctuliger*) and Sept (*polionotus*), female with egg in oviduct in Sept in NW Mato Grosso (*punctuliger*), and fledglings following adults near Belém (Pará) in Jun-Oct. Nest an open deep cup, constructed of tightly woven fine roots and grass stems, sometimes decorated on outside with fresh mosses and decomposing leaves, suspended by rim within 2-5 m of ground in horizontal fork of slender branch. Normal clutch 2 eggs, white, with dark reddish, chocolate-brown or grey spots and lines larger and more densely distributed at large end; both sexes share incubation duties during day, both also feed nestlings; no information on duration of incubation and nestling periods.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Generally uncommon throughout its extensive range. This includes numerous large parks and biological reserves, examples being Jaú and Tapajós National Parks and Cristalino State Park, in Brazil, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Caura Forest Reserve, Alto Orinoco-Casiquiare Biosphere Reserve and Yapacana National Park, in Venezuela; also a number of indigenous reserved zones that contain vast expanses of intact habitat. An exception is NE Brazil, where race *distans* appears to be highly threatened owing to the almost complete destruction of lowland evergreen forest in Alagoas and Pernambuco, in the wake of a burgeoning sugar-cane industry in the past few decades. Efforts should be made to preserve any intact lowland forest patches in this region, and censuses are needed in order to determine current population levels of *distans*.

**Bibliography.** Alverson, Moskovits & Shopland (2000), Alverson, Rodriguez & Moskovits (2001), Cory & Hellmayr (1924), English (1998), Foster *et al.* (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Meyer de Schauensee & Phelps (1978), Noxas (1970), O'Neill & Pearson (1974), Oniki & Willis (1983b), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Peixoto Velho (1932), Pinto (1953), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönewetter & Meise (1967), Schultenberger & Awbrey (1997a), Servat (1996), Sick (1993), Snethlage (1935), Stotz *et al.* (1996), Terborgh *et al.* (1990), Willis (1984d), Zimmer, J.T. (1933a), Zimmer, K.J. (2003a), Zimmer, K.J. & Hilty (1997), Zimmer, K.J., Parker *et al.* (1997).

## 30. Uniform Antshrike

### *Thamnophilus unicolor*

**French:** Batare unicolore **German:** Einfarbameisenwürger **Spanish:** Batará Unicolor

**Taxonomy.** *Dysithamnus unicolor* P. L. Slater, 1859, Pallatanga, Chimborazo, Ecuador.

Forms a superspecies with *T. aethiops*. Re-examination of races needed; nominate and *grandior* possibly intergrade in SW Colombia (Nariño); original description of male *caudatus* may have been based on subadult specimen. Three subspecies recognized.

**Subspecies and Distribution.**

*T. u. grandior* Hellmayr, 1924 - Colombia (locally on all Andean slopes) and E slope in Ecuador and N Peru (S to N San Martín).

*T. u. unicolor* (P. L. Slater, 1859) - Pacific slope in Ecuador.

*T. u. caudatus* Carraker, 1933 - E Andean slope in C Peru (S San Martín S, locally, to Cuzco).

**Descriptive notes.** 14-16 cm; 20-24 g. Male is uniform blackish-grey; rarely, small white tips on outer rectrices; iris light grey or grey. Female has rufous crown, grey head side, lores and chin; upperparts, wings and tail yellowish red-brown, underparts paler and more ochraceous than above. Subadult is like female, but with buffy tips to greater wing-coverts. Race *grandior* has longer

tail than nominate, male outer rectrices with white tips; *caudatus* male probably not diagnosably different from previous, but female is darker and more rufous. **VOICE.** Male loudsong a short and slow-paced (e.g. 6 notes, 2-4 seconds) series of low-pitched, complaining notes at steady pace and even pitch, first note typically sounding slightly more intense; female song similar, but typically starts at slightly higher pitch and rises slightly. Calls include a low-pitched, raspy series of 3-4 notes, first longer; a rattle that begins with distinct, sharp bark; also long downslurred note, and raspy growl.

**Habitat.** Understorey of evergreen forest, primarily at 1200-2300 m, occasionally to 600 m and to 2900 m, in regions often drenched in fog. Mostly in dense, wet undergrowth, both within forest, especially at light-gaps, and at borders.

**Food and Feeding.** Little published. Feeds primarily on insects and other arthropods, but stomach contents also contained seeds. Forages in pairs or singly, mostly at 1-3 m, sometimes to 8 m, in shrubby forest borders and openings, crowns of understorey saplings and dense stands of bamboo; progresses by short hops, separated by pauses of up to several seconds to several minutes to scan for prey. Reaches out, up or down, or lunges to glean arthropods from all leaf, stem, vine and branch surfaces with quick stabbing motions of the bill; also commonly probes at bamboo nodes and bases of spines for concealed arthropods. Often perches on vertical stems. At times probes dead-leaf clusters or, rarely, sally-gleans. Occasionally joins understorey mixed-species flocks of insectivores and groups of ant-following birds, but more often alone.

**Breeding.** No previously published information. Nest (from photograph) a deep cup of fibres, with outer layer of green vegetation, possibly moss, hanging below cup. Eggs creamy white with numerous large blotches and small spots of brownish-purple, lavender or red.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Poorly known; considered uncommon to locally fairly common throughout its range. In Colombia, occurs in La Planada Nature Reserve and along the Cali-Buenaventura road; observed at Buenaventura (Piñas), and on the Nono-Mindo Road and at Mindo, in Ecuador; also recorded at Abra Patricia, in Peru. No immediate threats, although all species restricted to middle-elevation montane evergreen forest of N & C Andes are recognized as being generally at risk, owing primarily to extensive deforestation for agriculture.

**Bibliography.** Cory & Hellmayr (1924), Fjeldså & Krabbe (1990), Hilty (1974, 1997), Hilty & Brown (1986), Isler & Whitney (2002), Miller (1963), Oates & Reid (1903), Olivares (1969), Parker (2003a), Parker & Carr (1992), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robles (2003), Schulenberg & Awbrey (1997a), Sclater & Salvin (1879), Stotz *et al.* (1996), Whitney (2003a), Zimmer, J.T. (1933a), Zimmer, K.J. (2003a).

## 31. Plain-winged Antshrike

### *Thamnophilus schistaceus*

**French:** Batara à ailes unies **German:** Schiefergrauer Ameisenwürger **Spanish:** Batará Alillano  
**Other common names:** Black-capped Antshrike

**Taxonomy.** *Thamnophilus schistaceus* d'Orbigny, 1837, Cochabamba, Bolivia.

Closely related to *T. murinus*. Proposed races *dubius* (E Peru), which represents an intermediate plumage in a broad cline, and *inornatus* (C Brazil), which represents the end of a cline and intergrades broadly with nominate, are synonymized with nominate. Race *heterogynus* may be specifically distinct. Three subspecies currently recognized.

#### **Subspecies and Distribution.**

*T. s. heterogynus* (Hellmayr, 1907) - extreme E Colombia (E Vaupés, presumably this race) and WC Amazonian Brazil (lower R Japurá, middle R Jaú, and both banks of R Solimões from R Juruá and lower and middle R Purus E to R Madeira).

*T. s. capitalis* P. L. Sclater, 1858 - SE Colombia (E base of Andes S from Meta), E Ecuador and NE Peru (N of R Marañón and R Amazon).

*T. s. schistaceus* d'Orbigny, 1837 - EC & SE Peru (S of R Marañón and R Amazon), S Amazonian Brazil (S of lower R Juruá and middle R Purus, and E from R Madeira to R Tocantins, S to Acre, Rondônia, N & W Mato Grosso and S Pará) and N Bolivia (S to C Santa Cruz).

**Descriptive notes.** 13-14 cm; 19-21 g. Male is grey, slightly darker on upperparts; wings and wing-coverts slightly brownish, edged grey; plumage darker in W ("*dubius*"), paler with whitish throat and belly in E ("*inornatus*"); iris reddish-brown. Female has crown rufous, upperparts yellowish olive-brown, underparts light olive-brown; as with male, darker in W and paler in E. Subadult is similar to adult female, but underparts variably cinnamon-tawny, olive-yellow or pale drab brown, yellow on sides and crissum. Race *capitalis* male has crown black; *heterogynus* female has upperparts rufous-brown, underparts rich

ochraceous. **VOICE.** Loudsong a slightly accelerating series of similar notes at same pitch, ending in sharply downslurred note that "falls off" to a lower pitch; number of notes variably 5-15, pace also varies. Differences somewhat regional, *heterogynus* differs in having notes of more abrupt quality, delivered faster than most, first note at slightly lower pitch; softsong a series of soft "pip" notes. Calls include long, slightly downslurred, somewhat plaintive note, often repeated in long series, also soft nasal note, quiet whistled note, and short growls given rapidly in alarm.

**Habitat.** Mid-storey of upland and seasonally flooded lowland evergreen forest, to 1100 m. Appears to prefer seasonally flooded forest in regions where sympatric with *T. murinus*. Chiefly in forest interior, but sometimes in dense vegetation at forest edge or in adjacent second growth.

**Food and Feeding.** Little published. Feeds on variety of insects and arthropods. Pairs or individuals forage mostly at 5-10 m, occasionally lower, or to 30 m above ground, particularly in woody vine tangles near trunks and in interior portions of middle-storey trees; sits fairly upright and peers about (mostly upwards) for several seconds or more between perch changes. Typically, moves quickly from tree to tree through home range, but also remains in same dense tangle for some time. Primarily sally-gleans, also hover-gleans, for distances of 0-1-2 m to obtain items from undersides of overhanging green leaves, quite often fluttering down to lower perch to manipulate and con-

## Family THAMNOPHILIDAE (TYPICAL ANTbirds)

### SPECIES ACCOUNTS

sume prey; also perch-gleans from leaf, stem, vine and branch surfaces with quick, stabbing motions of the bill. Occasionally explores clusters of dead leaves. Despite published statements to the contrary, routinely joins mixed-species understorey and mid-level flocks that move through its home range, although is not a permanent flock-member. One published record of ant-following from Brazil (Pará): an individual attended a swarm of *Eciton burchelli* for a few minutes, perched at 0.4 m, sallied to ground for flushed arthropod prey.

**Breeding.** Little recorded. Two nest descriptions from Brazil, in Feb and Oct, and two from Peru, in Mar and Sept. Nest a shallow cup constructed of coarse plant fibres, dried leaves, roots and stems, without finer lining, variously covered on outside with green moss, lichens or fungus-whitened twigs, suspended by rim within 2 m of ground in horizontal fork of slender branches among foliage, once with cluster of leaves hung over the top within 3 cm of rim. Normal clutch 2 eggs, creamy white, mottled and blotched with dark brown and pale lavender, the brown marks crowded around larger end; incubation by both sexes during day; no information on incubation and nestling periods.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout its extensive range. This includes vast areas of intact, protected habitat, e.g. Yasuni National Park, in Ecuador, Tambopata-Candamo Reserved Zone and Manu National Park and Biosphere Reserve, in Peru, Jaú and Tapajós National Parks and Cristalino State Park, in Brazil, and Noel Kempf Mercado National Park, in Bolivia.

**Bibliography.** Álvarez (1994), Alverson, Moskovits & Shopland (2000), Alverson, Rodríguez & Moskovits (2001), Cory & Hellmayr (1924), English (1998), Hellmayr (1910), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, M.L. *et al.* (1998), Isler, P.R. & Whitney (2002), Killen & Schulenberg (1998), Munn (1985), O'Neill & Pearson (1974), Olivares (1964a), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Remsen & Parker (1984), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg (2003), Schulenberg (1983, 2003), Siek (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Terborgh *et al.* (1990), Whittaker (2003a), Willis (1984d), Zimmer, J.T. (1930, 1933b), Zimmer, K.J. (2003a).

## 32. Mouse-coloured Antshrike

### *Thamnophilus murinus*

**French:** Batara souris **German:** Braunflügel-Ameisenwürger **Spanish:** Batará Murino

**Taxonomy.** *Thamnophilus murinus* P. L. Sclater and Salvin, 1868, Manaus, Amazonas, Brazil. Closely related to *T. schistaceus*. Race *cayennensis* possibly represents the extreme of a cline of plumage variation of nominate race; further study required. Three subspecies currently recognized.

#### **Subspecies and Distribution.**

*T. m. cayennensis* Todd, 1927 - French Guiana and NE Amazonian Brazil (Amapá, N Pará).

*T. m. murinus* P. L. Sclater & Salvin, 1868 - S Venezuela (Amazonas, Bolívar), Guyana, Surinam, extreme EC Colombia (E Guiana, E Vaupés) and Brazil N of R Amazon (from both banks of upper R Negro E to at least NE Amazonas).

*T. m. canipennis* Todd, 1927 - E Ecuador, E Peru (S to Ucayali and along base of Andes to NW Madre de Dios), extreme SE Colombia (Amazonas), W Brazil (E to R Japurá and, S of R Amazon, to R Madeira) and extreme N Bolivia (E Pando).

**Descriptive notes.** 13-14 cm; 17-20 g. Male is grey above, crown faintly barred darker, concealed white interscapular patch; wings dark yellowish-brown (more rufous in E), wing-coverts greyer, tipped buffy white; tail brownish-black and grey, tipped white; underparts paler, especially on throat and belly, central belly often white; iris grey or, often, brown. Female has forehead and crown dull rufous-brown, upperparts more olive-brown, wings brown (more rufous in E), wing-coverts and wings tipped and edged drab buffy white; tail warm dark brown, outer rectrices thinly tipped whitish; underparts pale grey, tinged yellowish-

brown on breast, sides and crissum, olive on flanks. Race *cayennensis* male has wing colour more reddish-brown than nominate; *canipennis* male has wings and wing-coverts grey, tipped and edged greyish-white, covert tips forming thin line, iris grey. **VOICE.** Loudsong a slightly accelerating series of up to c. 15 similar notes, very like that of *T. schistaceus* except notes becoming much shorter and descending only slightly in pitch, last 1-2 at higher pitch instead of falling. Call nasal and abrupt; in alarm a flat, raspy whine, or a clear note that becomes a raspy growl; also variable whines and abrupt notes.

**Habitat.** Mid-storey of lowland evergreen forest, to 1000 m; locally up to 1300 m in Venezuelan tepuis. Very much a bird of *terra firme* forest and forest borders; unlike *T. schistaceus*, not usually found in seasonally flooded forest. Most common in the sandy-soil forests of the Guianan region.

**Food and Feeding.** Little published. Feeds on variety of insects, especially katydids (Tettigoniidae) and grasshoppers (Acrididae), beetles (Coleoptera), bugs (Hemiptera), and adult and larval lepidopterans; also spiders and other arthropods. Pairs or individuals forage 2-25 m above ground, most commonly at 10-15 m in habitats with tall canopy, at 3-8 m in other habitats; progresses by hops and short flights, with frequent pauses to scan for prey. Takes prey by perch-gleans, sally-gleans or hover-gleans from all leaf, stem, vine and branch surfaces; perch-gleans with quick, stabbing motions of the bill. Less frequently associated with mixed-species flocks than is *T. schistaceus*, but occasionally joins understorey flocks of other antbirds, woodcreepers (Dendrocolaptidae) and foliage-gleaners (Furnariidae) as they move through its home range. Rarely recorded attending swarms of army ants (*Eciton burchelli*).

**Breeding.** Little recorded. Jan, May and Sept in French Guiana, and Aug-Nov in Brazil. Nest a dark-coloured open cup composed of rough black rhizomorphs surrounding branched rootlets, lined with black and brown rhizomorphs, decorated externally with dried leaves and twigs, suspended by rim from horizontal fork (attached to branches by smooth black rhizomorphs) 2-3 m above ground in understorey sapling or bush. Normal clutch 2 eggs, yellowish-white, with tangle of dark chestnut-brown spots, lines and hairlines "concentrated mostly on top third"; both sexes incubate during day. At a nest in Brazil (Manaus), both nestlings were parasitized by, respectively, 16 and 10 fly larvae.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout most of its extensive range; less common in W Amazonia. Vast areas of protected suitable habitat exist

within its range: examples include Iwokrama Forest Reserve, in Guyana, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve, in Peru, Jau National Park, in Brazil, and Alto Orinoco-Casiquiare Biosphere Reserve, Caura Forest Reserve and Imataca Forest Reserve and El Dorado, in Venezuela. Somewhat sensitive to selective logging.

(1933b), Zimmer, K.J. (2003a).

### 33. Upland Antshrike

#### *Thamnophilus aroyae*

**French:** Batará montagnard    **German:** Hochland-Ameisenwürger    **Spanish:** Batará Montano

**Taxonomy.** *Dysithamnus aroyae* Hellmayr, 1904, Oroya, Inambari Valley, 3000 ft [c. 900 m], Puno, Peru.

Relationships uncertain. Monotypic.

**Distribution.** Extreme SE Peru (Puno) and NW Bolivia (La Paz, Cochabamba).

**Descriptive notes.** 13-14 cm; 19-21 g. Male is grey, crown sometimes blackish, pale interscapular patch vestigial or absent; wings and tail brownish-black, wing-coverts dotted white, tail tips spotted white; posterior underparts faintly to obviously barred, crissum feathers tipped white. Female has crown dark rufous, ear-coverts white-spotted dark grey, upperparts and wings dark olive-brown; tail blackish-brown, outer rectrices tipped white; underparts olive-brown, tinged clay colour, throat and centre of belly pale buff. Juvenile male resembles female, but buff wing-covert spots and tail tips; subadult male is like adult except wings brownish. **VOICE.** Loudsong a

short (3-6 notes, duration highly variable) series of evenly paced nasal notes, first and last notes slightly lower-pitched, final note usually like preceding ones but longer or, occasionally, transformed into a snarl or omitted entirely. Calls include nasal note c. 0.4 seconds long that is often repeated irregularly, and slightly downslurred snarl.

**Habitat.** Montane evergreen-forest edge and adjacent second growth, typically in dense thickets, often those with bamboo, from 600 m to 1700 m. Sometimes found in forest interior, but no more than c. 30 m from edge.

**Food and Feeding.** Little known. Feeds primarily on insects, probably also other arthropods; six stomachs all contained insects, including beetles (Coleoptera) and a 15 × 2 mm caterpillar (Lepidoptera), one also held two seeds measuring 2 × 1 mm. Pairs or individuals forage at 1.5-3 m, rarely to 6 m, in very dense, large-leaved bushes and vine tangles. Techniques consist mainly of vertical sally-gleans of c. 15 cm to underside of leaves, including bamboo, and perch-gleans to woody stems and branches, vine tangles around tree trunks, bamboo leaves, and tops of ferns. Occasionally searches clusters of dead bamboo and other leaves trapped above ground in thickets. Does not regularly join mixed-species flocks.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Bolivian and Peruvian Lower Yungas EBA. Was possibly once restricted to shrubby habitats created by natural landslides; with the arrival of humans, may be spreading along roads and other man-made clearings.

**Bibliography.** Cory & Hellmayr (1924), Isler & Whitney (2002), Parker (2003a), Parker & Bailey (1991), Parker *et al.* (1991), Perry *et al.* (1997), Remsen (2003b), Remsen & Parker (1984), Remsen *et al.* (1982), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1933b).

## 34. Western Slaty Antshrike

### *Thamnophilus atrinucha*

**French:** Batará à nuque noire

**Spanish:** Batará Pizarroso Occidental

**German:** Westlicher Tropfenameisenwürger

**Other common names:** Slaty Antshrike (when merged with members of *T. punctatus* superspecies)

**Taxonomy.** *Thamnophilus atrinucha* Salvin and Godman, 1892, Panama.

Formerly considered conspecific with *T. punctatus*, *T. stictiocephalus*, *T. sticturus*, *T. pelzelni* and *T. ambiguus*, but now thought not to belong in this group (see page 450). Described form *subcinerus* (N Colombia) is regarded as a clinal variant of nominate. Two subspecies recognized.

#### Subspecies and Distribution.

*T. a. atrinucha* Salvin & Godman, 1892 - Caribbean slope from S Belize and NE Guatemala S to N Colombia (including Magdalena Valley) and NW Venezuela (E to Trujillo, E side of L Maracaibo), and Pacific slope in NW Costa Rica and from C Panama (Coclé) S to extreme NW Peru (Tumbes). *T. a. gorgonae* Thayer & Bangs, 1905 - Gorgona I, off Cauca, W Colombia.

**Descriptive notes.** 15 cm; 21-24 g. Male is mostly grey, darker above, with black crown with geographically variable amounts of grey in forehead, black on centre of back, white interscapular patch (normally concealed), black outer scapulars, wings and tail, scapulars and flight-feathers edged white, wing-coverts and tail tips spotted white, median white spots on outer rectrices; darkness of plumage varies geographically, mostly along clines, with palest in NE Colombia (Magdalena and La Guajira: "subcinerus") and in Ecuador, darkest in W Venezuela (at base of Sierra de Perijá). Female is olive-brown with tinge of clay color.

our above, except forehead and crown tinged dull reddish-brown, dark brown wings and tail, wing-coverts spotted buffish-white, remiges and tail edged pale buff, and dusky cinnamon to pale ochraceous-white below, palest on throat; as with male, darkness of plumage geographically (clinally) variable. Subadult male resembles adult, but tinged buffy yellow to brown. Race *gorgonae* differs from nominate in having male forecrown extensively grey, female underparts tawny-cinnamon with throat only slightly paler than breast. **VOICE.** Loudsong a rapidly delivered (e.g. 19 notes, 2-3 seconds), usually uncountable, series of emphatic notes, nearly level in frequency and constant in pace, ending with longer note at slightly higher pitch; softsong a long series that begins slowly and then accelerates; rattle a loud bark followed by a roll of abrupt notes. Calls include "caw" often in groups of 2-4, a bark (without ensuing rattle), also more complex notes, apparently scolds.

**Habitat.** Understorey and mid-storey of lowland and foothill semi-deciduous forest, vine-rich moist evergreen forest, and edges of wet evergreen forest; also widespread in second growth in many previously forested areas. To 500 m in Guatemala, Nicaragua and Honduras, to 1000 m in Costa Rica and Panama, and to 1500 m in Colombia, Ecuador and Venezuela.

**Food and Feeding.** Feeds primarily on insects, including adult and larval Lepidoptera, katydids (Tettigoniidae), crickets (Gryllidae), grasshoppers (Acrididae), mantids (Mantidae), stick-insects (Phasmatidae), true bugs (Hemiptera, including Reduviidae), cicadas (Cicadidae), beetles (Coleoptera, including Cerambycidae and Curculionidae) and ants (Formicidae), and also other arthropods, including spiders and scorpions (Scorpiones); also small lizards. Takes surprisingly large prey for its size, spending considerable time beating and mandibulating larger items, and removing wings, urticating spines and other appendages before swallowing. Pairs or individuals forage 1-30 m above ground, mostly at 1-10 m (with central tendency of 2-3 m), progressing by short, heavy hops (which conspicuously move the vegetation), separated by pauses of up to 15 seconds (or more) to scan for prey, typically from horizontal branches. Commonly leans forwards and cranes neck to peer under leaves; also regularly inspects suspended dead-leaf clusters, dead palm fronds, and green leaves showing signs of extensive insect damage. Mostly perch-gleans; reaches out, up or down, or lunges to glean prey from all leaf, stem, vine and branch surfaces with quick stabbing motions of bill; also makes short (less than 1 m) upward-directed hover-gleans to take prey from undersides of overhanging vegetation. Often associated with mixed-species flocks (more commonly during non-breeding season) moving through its home range, but more frequently alone. In Panama, regularly attends army-ant swarms on Barro Colorado I (in 21 years of observation recorded at 524 swarms, mostly of *Eciton burchelli*), but in 68 instances those of smaller *Labidus praedator*), but not an habitual or even persistent follower, usually drifting away from swarms after a short period; at swarms, regularly supplanted by *Gymnophytus leucaspis* and *Phaenostictus mcleannani*. When foraging over ants, usually perches less than 1 m up, taking prey by short sallies to ground or nearby foliage, or by reach-and-glean. On Barro Colorado I, also recorded as visiting window screens and other man-made structures to glean insects attracted by artificial lights.

**Breeding.** Jan-Sept in Costa Rica and Dec-Oct (peak May-Aug) in Panama. Nest built by both sexes, commencing on average 10 days prior to egg-laying, a thin-walled cup loosely woven (contents usually visible from below) of fine rootlets and vegetable fibres, coarser on outside, usually lined with black, shiny rhizomorphs, often decorated externally with mosses that may be woven into the rhizomorphs of inner layer, suspended by rim in horizontal fork 1-4 m up in slender branch of understorey sapling or slender bush. Normal clutch 2 eggs, typically laid two days apart, creamy white, heavily spotted and blotched with various shades of brown and purple, more concentrated on larger end; regular incubation begins when clutch complete, by both sexes during day, by female alone at night, period typically 15-16 days; chick hatches blind, dark-skinned, without down; both parents brood and feed young, which after 7-8 days brooded only at night (by female) or during strong daytime rains; young leave nest at 9-10 days, initially remain concealed in vegetation high above ground, but continue to be fed by adults for up to 38-42 days, and forage with them at least until 50-60 days after leaving nest; both parents perform distraction displays to potential predators near active nests or fledglings, raise crest, part back feathers to reveal white interscapular patch, spread wings and tail, and flutter about as if injured. Nest predation can be high; of 32 nests followed at Barro Colorado I, Panama, only 10% successfully fledged one or more young, with interval between loss of one nest and beginning rebuilding of next 1-4 days, interval until start of second clutch following predation 9-14 days; at mainland sites in Panama Canal area, however, success was higher, 46% for 54 nests and 21% for 81 nests in two successive years; in one study, most important nest predators were nocturnal mammals.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout much of its range. This includes a number of protected areas, such as La Selva Biological Reserve, in Costa Rica, Soberania and Darién National Parks and Nusigandi Forest Reserve, in Panama, and Maquipucuna Reserve and Rio Palenque Science Centre, in Ecuador. Recently found to occur on the Pacific slope of Costa Rica at Santa Rosa National Park, and in Peru in the Tumbes National Reserve, where at least five territories located in Jan 2001. These extend the known range of the species to include two additional large, protected areas. Ability to colonize and thrive in forest-edge and second-growth forest habitats gives it a higher degree of tolerance of human habitat disturbance than exhibited by most forest-dwelling antbirds.

**Bibliography.** Blake & Loiseleur (1991), Brumfield & Capparella (1996), Carriker (1910), Cody (2000), Cory & Hellmayr (1924), Gradwohl & Greenberg (1980), Greenberg & Gradwohl (1980, 1985, 1986), Hilty (2003a), Hilty & Brown (1986), Howell & Webb (1995a), Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Johnson (1953), Lockwood (1999), Meyer de Schauensee & Phelps (1978), Monroe (1968), Oniki (1975), Parker & Carr (1992), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Robinson *et al.* (2000), Roper (2000), Roper & Goldstein (1997), Salaman, Donegan & Cuervo (2002), Schamske & Brokaw (1981), Schönwetter & Meise (1967, 1988), Skutch (1934, 1940, 1945a, 1946, 1954, 1969c, 1976, 1996a), Slud (1960, 1964), Stiles & Skutch (1989), Stone (1918), Sturgis (1928), Wetmore (1972), Whitney (2003a), Willis (1980, 1988b), Willis & Eisenmann (1979), Zimmer (2003a).

## 35. Northern Slaty Antshrike

### *Thamnophilus punctatus*

**French:** Batará tacheté

**Spanish:** Batará Pizarroso Punteado

**German:** Nördlicher Tropfenameisenwürger

**Other common names:** Eastern/Guianan Slaty Antshrike; Slaty Antshrike (when merged with others of superspecies); Peruvian Slaty Antshrike (*leucogaster*)

**Taxonomy.** *Lanius punctatus* Shaw, 1809, Cayenne.

Forms a superspecies with *T. stictiocephalus*, *T. sticturus*, *T. pelzelni* and *T. ambiguus*; all formerly considered conspecific, with *T. atrinucha* traditionally included too (see page 450). Race *leucogaster* (with *huallagae*) has sometimes been treated as a separate species. Race *huallagae* was originally placed with *T. amazonicus*. Four subspecies recognized.

#### Subspecies and Distribution.

*T. p. punctatus* (Shaw, 1809) - E & S Venezuela (Amazonas, Bolívar, Sucre, Monagas, Delta Amacuro), the Guianas, and Brazil N of R Amazon and E of R Negro (in NE Amazonas, Roraima, N Pará, Amapá); sight records from extreme E Amazonian Colombia (Guania, Vaupés) probably this race.

*T. p. interpositus* Hartert & Goodson, 1917 - E base of Andes in W Venezuela (Táchira, Apure, Barinas) and Colombia (Boyacá, Meta, W Caquetá).

*T. p. huallagae* Carriker, 1934 - R Huallagala drainage in N Peru (San Martín).

*T. p. leucogaster* Hellmayr, 1924 - R Maraño drainage in extreme S Ecuador (Zamora-Chinchipe) and N Peru (Amazonas, Cajamarca).

**Descriptive notes.** 13-15 cm; 19-21 g (*punctatus*), 16-18 g (*leucogaster*). Male nominate race has crown black, forehead mostly grey; back grey with few black feather tips, white interscapular patch (concealed); outer scapulars and wings black, boldly spotted and edged white; tail black, tips and median spots on outer feathers white; underparts grey, belly whitish in some regions. Female has crown tawny, back yellowish olive-brown with few or no blackish feather tips, wings dark brown, coverts spotted white, flight-feathers edged pale buff, tail reddish yellow-brown, tips and median spots on outer feathers white, underparts light buffy olive, whitest on throat and belly. Race *interpositus* male has forehead and upperparts black except for a few grey feather tips, underparts dark grey, female darker and more clay-coloured than nominate; *leucogaster* has forehead mostly black, crown usually with hidden white spots, upperparts dark grey with few or no black patches, underparts grey, extensively white on centre of belly, female back brown, underparts white except for light buffy olive across breast and on sides and flanks; *huallagae* has forecrown black, crown usually with hidden white spots, back and underparts darker grey than nominate, female underparts more olive, less yellow. **VOICE.** Loudsong an accelerating series of usually 10-15 progressively shorter notes starting with laboured, slow-paced notes that are countable, ending with trill of abrupt uncountable notes often sounding higher in pitch, pace somewhat variable regionally, race *leucogaster* fastest; rattle a series of wooden notes, relatively slow for a rattle, fastest in *leucogaster*. Calls include short "caw", longer "caw", and abrupt raspy note.

**Habitat.** Understorey and mid-storey of lowland evergreen-forest edge, white-sand forest, savanna woodland, deciduous and semi-deciduous woodland, gallery forest and secondary forest, mostly below 1000 m; locally to 1500 m in Venezuelan tepuis (*punctatus*), and to 1200 m in R Maraño drainage (*leucogaster*).

**Food and Feeding.** Little published. Feeds on variety of insects, including lepidopteran larvae, katydids (Tettigoniidae) and grasshoppers (Acrididae), mantids (Mantidae), weevils (Curculionidae), true bugs (Hemiptera, Homoptera) and neuropterans (Ascalapidae), as well as other arthropods. Pairs or individuals forage 1-12 m above ground, mostly at 1-6 m, progressing by short hops, separated by pauses of up to several seconds to scan for prey. Reaches out, up or down, or lunges, gleaning prey from all leaf, stem, vine and branch surfaces with quick stabbing motions of the bill; also makes short (less than 1 m) upward-directed sallies to glean items from undersides of overhanging vegetation; occasionally charges into hanging dead-leaf clusters to dislodge insect prey. A male in N Peru (*leucogaster*) once observed to forage for c. 2 minutes on ground, by flipping over leaves. Habitually shivers its tail while foraging, particularly immediately following perch changes. At times associates with mixed-species flocks moving through its home range; occasionally follows army ants (*Eciton burchelli*).

**Breeding.** Little published. In Brazil, nests and recently fledged young recorded in Oct-Dec in Manaus area (Amazonas), nest in Aug in Pará; nests in the dry season, with a nest in mid-Aug, in French Guiana. Nest a cup composed of shreds of plant fibres, with inner lining of long strands of fine grasses and blackish horsehair-like rhizomorphs, suspended by rim from horizontal fork; a nest in Brazil (near Manaus) was of black and brown rhizomorphs attached to rotten pieces of palm

leaves (with some fungi growing over them), decomposing grass and roots, lined with branched rootlets attached to rhizomorphs (which joined nest to branches), suspended from a 45° fork 1 m up in a *Ternstroemia* bush; another in Brazil (N bank of Amazon in Pará) was a regular and well-constructed cup, the outside decorated with green moss, placed low in bush on a riverbank, and a more vaguely described nest from Venezuela appears to be similar; a nest in French Guiana was made from a lot of mosses, lined with fibres of a *Marasmius* fungus, placed 46 cm above ground in small shrub. Normal clutch 2 eggs, pale creamy buff with irregularly distributed reddish-brown blotches, once white with dark spots and stripes.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Nominate race is fairly common to common throughout its rather extensive range. It is not restricted to one habitat, and benefits from human encroachment under certain conditions, e.g. population density increased after selective logging in a managed forest in Venezuela. In contrast, the two races in S Ecuador and Peru should be considered at risk, as their respective geographical ranges are extremely limited, and the dry-forest habitats which they occupy are under intensive pressure from agricultural development. The situation may be most urgent for *hualtagae*, for which suitable habitat appears to be highly fragmented and restricted to remnant small patches of woodland; *leucogaster* is locally common in somewhat larger forest patches in the R Marañón drainage, but these areas are not formally protected, and danger of near-total habitat destruction persists. Creation of one or more dry-forest reserves in this part of the Marañón drainage could help to preserve a healthy population of the latter race, in addition to benefiting many other taxa with restricted ranges in the same region; these include Spot-throated Hummingbird (*Leucippus taczanowskii*), Marañon Spinetail (*Synallaxis maranonica*), Marañon Crescentchest (*Melanopareia maranonica*) and Black-capped Sparrow (*Arremon abeillei*), as well as the distinctive race *chinchipensis* of Necklaced Spinetail (*Synallaxis stictothorax*).

**Bibliography** Begazo *et al.* (2001), Belcher (1938), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Mason (1996), Meyer de Schauensee & Phelps (1978), Novas (1974), Oniki (1975), Oniki & Willis (1982), Pacheco & Whitney (1997), Parker (2003a), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Sneath (1935), Thiollay (1994), Tostain (2003), Tostain *et al.* (1992), Vleck & Vleck (1979), Whitney (2003a), Willis (1984, 1988b), Zimmer, J.T. (1933b), Zimmer, K.J. (2003a), Zimmer, K.J. & Hilty (1997).

## 36. Natterer's Slaty Antshrike

### *Thamnophilus stictocephalus*

**French:** Batara de Natterer

**German:** Natterers Tropfennameisenwürger

**Spanish:** Batará Pizarroso de Natterer

**Taxonomy.** *Thamnophilus stictocephalus* Pelzelin, 1868. São Vicente, Mato Grosso, Brazil.

Forms a superspecies with *T. punctatus*, *T. sticturus*, *T. pelzelni* and *T. ambiguus*; all formerly considered conspecific, with *T. atrinucha* traditionally included too (see page 450). Described races *saturatus* and *zimmeri* (both C Brazil) represent clinal variation of nominate, with which merged. Two subspecies recognized.

**Subspecies and Distribution.**

*T. s. stictocephalus* Pelzelin, 1868 - Brazil S of R Amazon (from R Madeira E to Marajó I and R Tocantins, in Pará, and SW to Rondônia and N & W Mato Grosso) and extreme N Bolivia (N Beni). *T. v. parkeri* Isler *et al.*, 1997 - extreme NE Bolivia in N Santa Cruz (Serranía de Huanchaca).

**Descriptive notes.** 14-15 cm; 19-22 g. Male has crown black, forehead black with some grey spots; black and grey upperparts, white interscapular patch (concealed); outer scapulars and wings black, boldly spotted and edged white; tail black, tipped white; underparts grey, whitish on belly. Female has crown rufous, back reddish yellow-brown, scapulars and wings dark brown, spotted and edged white, flight-feathers edged clay colour, tail dark brown, tipped white, underparts variably mixed light clay colour and light grey, paler on throat and belly. Race *parkeri* male has forehead extensively grey, back with few black spots, underparts paler than nominate with white centre of belly, female upperparts less reddish. Voice.

Loudsong an accelerating series (e.g. 20 notes, 3 seconds) of emphatic notes, generally level in frequency and pitch, sometimes rising or dropping off at end, only initial notes countable; rattle is a growl extending into a roll, so rapid that individual notes barely distinguishable. Calls include short and long "caw" notes and abrupt growl.

**Habitat.** Understorey and mid-storey of lowland evergreen-forest edge, deciduous and semi-deciduous woodland, and "islands" of sandy-soil forest within taller forest; from near sea-level along R Amazon to 700 m in Mato Grosso and Serranía de Huanchaca. Inhabits primarily sandy-soil patches, humid-forest edge and forest light-gaps along R Amazon; in stunted, semi-deciduous forest growing on rocky outcrops in N Mato Grosso. Farther S, where Amazonian forest gives way to more open habitats, has been found in gallery forest. In Huanchaca Mts, occurs along edges of large stands of evergreen forest surrounded by grassland and *cerrado*.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae, orthopterans such as katydids (Tettigoniidae) and grasshoppers (Acrididae), true bugs (Hemiptera), cicadas (Cicadidae) and beetles (Coleoptera), also other arthropods. Pairs or individuals forage 1-10 m above ground, progressing by short hops, with pauses of up to several seconds to scan for prey. Reaches out, up or down, or lunges to glean prey from all leaf, stem, vine and branch surfaces, using quick stabbing motions of the bill; also makes short (less than 1 m) upward-directed sallies to glean items from undersides of overhanging vegetation. Habitually shivers tail when foraging, particularly immediately following perch changes. Not known to join mixed-species flocks; occasionally follows army ants (*Eciton burchelli*).

**Breeding.** Unknown.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common throughout its range. This encompasses some large protected areas, e.g. Tapajós National Park, Caxiuanã National Forest and Cristalino State Park, in Brazil, and Noel Kempf Mercado National Park, in Bolivia. Dry-forest habitats occupied by this species could come under threat, but substantial populations exist within humid-forest regions that are largely intact and under no threat of development.

**Bibliography** Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Killean & Schulenberg (1998), Oren & Parker (1997), Parker (2003a), Schubarth *et al.* (1965), Sick (1993), Willis (1984d), Zimmer, J.T. (1933b), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

## 37. Bolivian Slaty Antshrike

### *Thamnophilus sticturus*

**French:** Batara à queue tachetée

**German:** Bolivien-Tropfennameisenwürger

**Spanish:** Batará Pizarroso Boliviano

**Taxonomy.** *Thamnophilus sticturus* Pelzelin, 1868, Engenho do Capitão Gama, Mato Grosso, Brazil. Forms a superspecies with *T. punctatus*, *T. stictocephalus*, *T. pelzelni* and *T. ambiguus*; all formerly considered conspecific, with *T. atrinucha* traditionally included too (see page 450). Monotypic.

**Distribution.** C & E Bolivia (Beni, Cochabamba, Santa Cruz), immediately adjacent Brazil (extreme W parts of Mato Grosso and Mato Grosso do Sul) and N Paraguay (Alto Paraguay).

**Descriptive notes.** 14 cm; 18-20 g. Male has crown black, forehead grey, grey extending deeply into crown; grey upperparts with a few black feathers centrally, white interscapular patch (concealed); outer scapulars and wings black, boldly spotted and edged white; tail black, tips and median spots white; underparts light grey, extensively white on belly. Female has crown bright reddish-brown, back yellowish olive-brown, scapulars and wings dark brown, spotted and edged white, flight-feathers edged pale buff, tail dark brown with white tips and median spots, underparts white, light yellowish-brown across breast and on sides, flanks and

crissum. **Voice.** Loudsong a series starting slowly and speeding up into rattling trill, rises in frequency and intensity, reaching peak near end of trill, then falls off; rattle a simple rapid repetition of abrupt notes highly variable in length and pace, short rattles tend to drop in frequency, longer rattles flatter. Call a "caw" note, variable in length, sometimes extended into harsh, downward-inflected growl.

**Habitat.** Understorey and mid-storey of dry semi-deciduous forest with, typically, extensive vine tangles, also gallery forest both in more open regions and within extensive stands of more humid forest, and second-growth forest; to 950 m.

**Food and Feeding.** Little published. Diet presumably arthropods. Forages in pairs or individually, 1-7 m above ground, progressing by short hops separated by pauses of up to several seconds to scan for prey. Main technique involves reaching out, up or down to glean prey items with quick stabbing motions of the bill; also makes short (less than 1 m) upward-directed or lateral sallies to vegetation. Habitually shivers tail when foraging, particularly immediately following perch changes. Not observed to join mixed-species flocks or to follow army ants.

**Breeding.** Almost no information available; egg size, but not coloration, known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common throughout its rather small range. Unfortunately, this region lacks large protected areas and has recently come under increased logging pressure. At one study site where selective logging took place, its population density increased after logging.

**Bibliography** Capper, Clay, Madroño & Mazar Barnett (2001), Capper, Clay, Madroño, Mazar Barnett, Burfield *et al.* (2001), Cory & Hellmayr (1924), Davis (1993), Flores *et al.* (2001), Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Parker (2003a), Schönwetter & Meise (1967), Sick (1993), Whitney (2003a), Zimmer (1933b).

## 38. Planalto Slaty Antshrike

### *Thamnophilus pelzelni*

**French:** Batara de Pelzelin

**German:** Planalto-Tropfennameisenwürger

**Spanish:** Batará Pizarroso del Planalto

**Taxonomy.** *Thamnophilus punctatus pelzelni* Hellmayr, 1924, Abrilongo, Mato Grosso, Brazil.

Forms a superspecies with *T. punctatus*, *T. stictocephalus*, *T. sticturus* and *T. ambiguus*; all formerly considered conspecific, with *T. atrinucha* traditionally included too (see page 450). Monotypic.

**Distribution.** C & E Brazil from E Maranhão, Ceará and Paraíba to N Minas Gerais and W Bahia and from E & S Mato Grosso and Goiás to N Mato Grosso do Sul, extreme N Paraná and W São Paulo.

**Descriptive notes.** 14 cm; 16-20 g. Male has crown black, forehead mixed with grey; upperparts grey with some black feathers centrally, white interscapular patch (concealed); wings brownish-black, boldly spotted and edged white, tail black, tips and median spots white; underparts light grey, throat and belly extensively white, belly often faintly tinged buff. Female has crown bright rufous, back cinnamon-rufous with sometimes a few blackish feather tips, wings dark brown, spotted and edged white, flight-feathers edged pale clay colour, tail mostly dark brown, tips white, underparts light cinnamon-buff, whitest on throat and belly. **Voice.**

Loudsong an accelerating series of rather harsh, dry notes (e.g. 20 notes, 5 seconds) ending with short roll, rises in pitch, then levels off, and occasionally falls slightly at end; rattle a simple rapid repetition of abrupt notes highly variable in length and pace, short rattles tend to drop in frequency, longer rattles flatter. Calls include a "caw" note of variable length, a longer whistle, and a flat, short growl.

**Habitat.** Understorey and mid-storey of deciduous and semi-deciduous forest, especially with vines (*mata-de-cipó* forest), and gallery forest; also locally at edge of evergreen forest; mostly at 400-800 m, locally to near sea-level in NE and to 1100 m in the Planalto. In S & W portions of range, confined mainly to gallery forest; common in deciduous and semi-deciduous woodland in N.

**Food and Feeding.** Little published. Feeds primarily on insects, including lepidopteran larvae, katydids (Tettigoniidae), grasshoppers (Acrididae), mantids (Mantidae), stick-insects (Phasmatidae), crickets (Gryllidae), true bugs (Hemiptera) and weevils (Curculionidae), and other arthropods, including spiders. Pairs, individuals or family groups forage 1-15 m above ground, mostly 1-5 m, progressing by short hops separated by pauses of 1-5 seconds to scan for prey. In *mata-de-cipó* forest, frequently forages in crowns of understorey trees covered with mats of viny vegetation, reaching out, up or down, or lunging to glean items from all leaf, stem, vine and branch surfaces, using quick stabbing motions of the bill; often lingers at green leaves with obvious insect damage, picking repeatedly at same spots. In gallery forest and dry forest with fewer vines, more often forages closer to ground,

moving from perch to perch by short wing-assisted hops, periodically dropping to ground to take prey from top of leaf litter, or occasionally making short upward-directed sallies to take items from undersides of overhanging vegetation. A pair observed in Chapada dos Guimarães (Mato Grosso) foraged opportunistically in a recently burned patch of gallery forest; perched on charred saplings less than 1 m up, and dropped to ground to take subsurface arthropods that emerged from still smouldering layers of topsoil. Habitually shivers its tail while foraging, particularly immediately after making a perch change. Frequently associates with mixed-species flocks passing through its home range. One record of six birds (which appeared to represent three pairs of adults, rather than a family group) attending army ants in ecotone between dry forest and *caatinga* in N Minas Gerais: they followed the ants for entire period of observation (c. 90 minutes), and were the most numerous bird species in attendance; from vertical and horizontal perches low (up to 0.75 m) over ants, individuals made mostly darting sallies to ground or to bare stems and branches for prey; one female leaned forwards from a low horizontal perch and repeatedly tossed dry leaves from the litter to reveal concealed arthropods; individuals aggressively displaced and supplanted one another from choice perches immediately above the swarm front, and sang and called repeatedly.

**Breeding.** Little recorded. Single published description of two nests, found in Oct, each an open cup suspended by rim from horizontal fork; one nest with 3 eggs, the other with 2, eggs whitish, with irregular reddish-brown speckling and blotches concentrated at larger end.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Common throughout most of its range. This includes a number of protected areas, e.g. Chapada dos Guimarães, Sete Cidades, Serra do Cipó and Serra da Canastra National Parks, and Chapada do Araripe National Forest. Highest densities found in NE part of range (Ceará, Pernambuco, Bahia), the dry-forest habitats of which are, however, largely unprotected and are being continually cleared for agricultural development and for cutting of firewood.

**Bibliography.** Cintra & Yamashita (1990), Coelho (1987), Cory & Hellmayr (1924), Ihering (1900), Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Motta-Júnior & Vasconcello (1996), do Nascimento *et al.* (2000), Olmos (1993), Parker (2003a), Ribon & Maldonado-Coelho (2001), Sick (1955, 1993), da Silva & Oniki (1988), Iubelis & Tomás (1999), Zimmer, J.T. (1933b), Zimmer, K.J. (2003a).

## 39. Sooretama Slaty Antshrike

*Thamnophilus ambiguus*

**French:** Batara de Sooretama

**Spanish:** Batará Pizarroso de Sooretama

**German:** Sooretama-Tropfenameisenwürger

**Taxonomy.** [*Thamnophilus naevius*] *ambiguus* Swainson, 1825. Minas Gerais, Brazil.

Forms a superspecies with *T. punctatus*, *T. sticticephalus*, *T. sticturus* and *T. pelzelni*; all formerly considered conspecific, with *T. atrinucha* traditionally included too (see page 450). Monotypic.

**Distribution.** SE Brazil in coastal region from S Sergipe S to Rio de Janeiro, extending inland in Minas Gerais (R Doce Valley); one probable sight record in extreme NE São Paulo.

**Descriptive notes.** 14–15 cm. Male has forehead and crown black, forehead with few grey spots; upperparts grey with central black patch, white interscapular patch (concealed); wings black, boldly spotted and edged white, tail black, tips and median spots white; underparts pale grey, often whiter on throat and belly. Female has crown warm tawny-brown, back olive-grey with clay-coloured tinge, a few blackish feather tips centrally, wings dark brown, spotted and edged white, flight-feathers edged pale clay colour, tail dark brown, tips and median spots white, underparts mixed clay colour and smoke-grey, whitest on throat and belly. **VOICES.** Loudsong an

accelerating series of rather harsh, dry notes (e.g. 20 notes, 5 seconds) ending with short roll, mostly even in pitch but rises slightly at start and sometimes falls slightly at end; rattle a rapid repetition of abrupt notes very variable in length and pace, short rattles tend to drop in frequency, longer rattles flatter. Calls include “caw” note, variable in length, typically downward-inflected, usually given singly, and more complex complaining note; also downward-inflected short growl, like a raspy “caw”.

**Habitat.** Understorey and mid-storey of lowland evergreen-forest edge, also woodland growing on sandy soil in coastal belt, including second growth near woodland; to 700 m. Favours forest edge and light-gaps within interior.

**Food and Feeding.** Little published. Feeds on insects and other arthropods, including moths and larval lepidopterans, cockroaches (Blattodea), beetles and borers (Coleoptera, including Bostrichidae), and ants (Formicidae). Forages in pairs or individually, or in family groups, mostly in thickets and vine tangles 1–10 m above ground, sometimes to 25 m; progresses by short hops, most often on horizontal branches but sometime climbing up vines wrapped around tree trunks, with pauses of up to several seconds to scan for prey. Reaches out, up or down or makes lunges to glean prey from all surfaces of leaves, stems, vines and branches, with quick stabbing motions of the bill; also makes frequent short (to 1.5 m) upward-directed sallies to take prey from underside of overhanging vegetation. Occasionally chases prey to the ground or picks through leaf litter. Habitually shivers its tail while foraging, especially immediately following perch changes. Often associates with mixed-species flocks. Recorded as rarely following army ants (*Eciton burchelli*).

**Breeding.** Little recorded. One published record of recently fledged young in Bahia (near Santo Amaro) in late Nov. Nest described as a crucible suspended from horizontal fork, typical of the genus. Eggs whitish with irregularly distributed purplish-brown and dark grey spots, denser on larger end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common in its relatively narrow range. This includes several protected areas, e.g. Monte Pascoal National Park, Pau Ecological Station, Porto Seguro Reserve, Linhares Natural Reserve, and Sooretama, Una and Crasto Biological Reserves.

**Bibliography.** Cory & Hellmayr (1924), Euler (1900), Ihering (1900), Isler, M.L. & Isler (2003a), Isler, M.L., Isler & Whitney (1997), Isler, M.L., Isler, Whitney & Walker (2001), Isler, P.R. & Whitney (2002), Moojen *et al.* (1941), Motta-Júnior (1990), Parker (2003a), Schönwetter & Meise (1967), Scott & Brooke (1985), Sick (1993), Stotz (1990b), Whitney (2003a), Willis (1984d), Zimmer, J.T. (1933b), Zimmer, K.J. (2003a).

## 40. Amazonian Antshrike

*Thamnophilus amazonicus*

**French:** Batara d'Amazonie

**Spanish:** Batará Amazónico

**German:** Amazonien-Tropfenameisenwürger

**Other common names:** Grey-capped Antshrike (*cinereiceps*)

**Taxonomy.** *Thamnophilus amazonicus* P. L. Slater, 1858, Rio Javari, north-east Peru.

Relationships uncertain; has been treated as forming a superspecies with *T. caerulescens*, but possibly closest to the *T. punctatus* superspecies. S of R Amazon plumage variation is clinal, but apparent habitat differences suggest that populations may be distinct, although geographical limits of the three S races are tentative; similarly, in NW, some specimens and sight descriptions from W Amazonia suggest intermediacy in plumage between nominate and *cinereiceps*, but plumage and habitat differences again support the maintaining of races; further research needed. Race *huallagae* of *T. punctatus* has sometimes been considered to belong in present species. Five subspecies currently recognized.

**Subspecies and Distribution.**

*T. a. cinereiceps* Pelzeln, 1868 - SW Venezuela (W Amazonas), EC Colombia (Vichada and Meta S to Caquetá and Vaupés) and NW Brazil (both banks of upper R Negro and along W lower bank S to R Solimões).

*T. a. divaricatus* Mees, 1974 - extreme E Venezuela (E Bolívar), the Guianas, and NE Brazil N of R Amazon (E of R Branco and R Negro, E to N Pará and Amapá).

*T. a. amazonicus* P. L. Slater, 1858 - SE Colombia (S Amazonas), extreme E Ecuador (E Napo), E Peru, W Brazil S of R Amazon and W of R Tapajós (S Amazonas and extreme W Pará S to Acre, Rondônia and W Mato Grosso) and N Bolivia (Pando, N La Paz, N Beni, NE Santa Cruz).

*T. a. obscurus* J. T. Zimmer, 1933 - SC Amazonian Brazil (S Pará between R Tapajós and R Tocantins). *T. a. paraensis* Todd, 1927 - E of R Tocantins in E Pará, W Maranhão and N Tocantins.

**Descriptive notes.** 14 cm: 17–21 g. Male nominate race has centre of forehead and crown black, side of head grey; back mostly black, rump grey, interscapular patch white; outer scapulars and wings black, boldly spotted and edged white; tail black, tips and median spots on outer rectrices white; underparts grey. Female has crown bright rufous, rest of head and underparts bright yellowish red-brown, upperparts deep olive, wings and tail patterned like male but browner. Flight-feathers edged pale olive. Race *cinereiceps* is smaller and paler than nominate, male crown grey, upperparts grey with a few black feathers on upper

back, female with anterior underparts mixed with grey, belly and crissum buff-tinged smoky white, flanks olive-grey; *divaricatus* male has side of head blackish-grey, back mixed black and grey, female underparts paler and greyer than nominate; *paraensis* male is paler below, often with faint white bars on belly, female with tail tinged reddish, lower underparts pale cinnamon-buff; *obscurus* is darkest, male mostly or entirely black above, dark grey below, female dark and often lacking pale tips of central rectrices. **VOICE.** Loudsong a long (e.g. 30 notes, 3 seconds) uncountable series that typically increases in speed and pitch initially, gradually levels off, then most often descends, although ending variable. Final notes may change in quality and/or strengthen or fade in intensity. Calls include long, downslurred, complaining “caw”, also an emphatic note with quality of a bark, and long raspy growl resembling a short rattle.

**Habitat.** Understorey and mid-storey of lowland evergreen forest, edges, and second growth, specific habitat preferences varying among races. In *N. cinereiceps* occurs in sandy-soil habitats, both in stunted savanna woodland growing on white-sand soil and in shrubby borders of taller *terra firme* and *igapó* forests, while *divaricatus* inhabits liana-rich parts of *terra firme* forest, locally in open forest near tepui summits and at river edges. Nominale race almost entirely confined to riverine viny borders and light-gaps in seasonally flooded *várzea* and *igapó*. Race *obscurus* more widely distributed in forest edges and openings, inside viny forest, dense secondary growth, and stands of *Guadua* bamboo within *terra firme* and transitional forests. Race *paraensis* is found primarily in second growth, less often in light-gaps in *terra firme* and *igapó* forests, rarely in *várzea*.

**Food and Feeding.** Little published. Feeds on a variety of insects, including lepidopteran larvae, katydids (Tettigoniidae), mantids (Mantidae), stick-insects (Phasmatidae) and beetles (Coleoptera), as well as spiders and other arthropods. Pairs or individuals forage mostly 5–17 m above ground, particularly in clusters of hanging vines along major tree trunks, and on fairly open large branches in interior portions of trees; routinely forages as low as 1 m in dense savanna woodland in SW Venezuela (*cinereiceps*), and also regularly in crowns of *Guadua* bamboo and interlacing vine tangles in SC Amazonian Brazil (*obscurus*). Advances with short hops separated by pauses to peer about; foraging pace faster than that of most congeners (perhaps most similar to *T. caerulescens*). Reaches out, up or down, or lunges to glean prey from leaf, stem, vine and branch surfaces, using quick stabbing motions of the bill; also frequently makes vertical jumping sallies to pluck prey from undersides of overhanging leaves; occasionally bends well over to look under branches. Frequently joins mixed-species flocks that come through its home range. Race *paraensis* recorded as occasionally attending army ants (*Eciton burchelli*).

**Breeding.** May–Jan in Brazil; food-carrying adults seen in Mar, Aug and Sept. Nest a deep cup 10 cm in diameter and 5 cm in depth, variably constructed with coarser materials on outside around finer material on inside, principally filiform stems of various plants, frequently with long black rhizomorph threads similar to horsehair, often ornamented with variable amounts of moss on outside, and suspended by rim from two slender branches of horizontal fork 1–3 m above ground in understorey bush or sapling. Normal clutch 2 eggs, creamy whitish with numerous violet-grey, reddish-brown or lilac spots, more concentrated at larger end; females observed carrying food, once to lianas where nest probably concealed.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Varies from being uncommon to being locally common. Extensive range includes vast areas of protected suitable habitat, examples being Brownsberg Nature Park, in Surinam, Yapacana National Park and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Tinigua and Amacayacu National Parks and Chiribiquete National Park, in Colombia, Pacaya-Samiria National Reserve, in Peru, Tapajós and Jau National Parks and Cristalino State Park, in Brazil, and Noel Kempf Mercado National Park, in Bolivia. Furthermore, this species adapts well to second growth in some portions of its range, thus rendering it less vulnerable to habitat disturbance.

**Bibliography.** Álvarez (1994), Cory & Hellmayr (1924), Estevão (1926), Haverschmidt & Mees (1994), Hellmayr (1912b), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Meyer de Schauensee & Phelps (1978), Novaes (1969, 1970, 1973, 1980, 1982), Oates & Reid (1903), Oniki & Willis (1983b), Oren & Parker (1997), Parker (2003a), Pinto (1953), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Sick (1993), Sneath (1935), Stotz *et al.* (1996), Terborgh *et al.* (1984), Thiollay (1994), Tostain (2003), Tostain *et al.* (1992), Willis (1984d), Zimmer, J.T. ## 41. Streak-backed Antshrike

### *Thamnophilus insignis*

**French:** Batará à dos rayé **German:** Tepui-Tropfenameisenwürger **Spanish:** Batará Insigne

**Taxonomy.** *Thamnophilus insignis* Salvin and Godman, 1884, Mount Roraima, 5000 ft [c. 1500 m], Venezuela.

Relationships uncertain. Two subspecies recognized.

#### Subspecies and Distribution.

*T. i. nigrofrontalis* Phelps, Sr. & Phelps, Jr., 1947 - extreme SW Venezuela (Macizo de Cuao-Sipapo, in W Amazonas).

*T. i. insignis* Salvin & Godman, 1884 - S Venezuela (tepui of Bolívar and E Amazonas), and Mt Roraima and its vicinity in extreme W Guyana and adjoining N Brazil (extreme N Roraima).

**Descriptive notes.** 16-17 cm; 24-30 g. Male has crown and upperparts black, some white feathers on crown and nape; white inter-scapular patch exposed as spots or streaks on back; scapulars and wings black, boldly spotted and edged white; tail black, tips and median spots on outer rectrices white; throat and underparts grey, paler posteriorly. Female is similar to male except forehead faintly spotted white, rear crown dark red-brown, underparts somewhat paler. Race *nigrofrontalis* female has forehead solid black. **VOICE.** Loudsong an accelerating series of similar notes (e.g. 13 notes, 2-5 seconds), rising in

pitch, then levelling, terminating in emphatic, higher-pitched, long nasal note. Calls include somewhat downslurred raspy growl, variable in length, and soft squeak or "peep".

**Habitat.** Understorey and mid-storey of montane evergreen forest, at 900-2000 m. Primarily in stunted (canopy below 10 m) forest dominated by melastome (*Melastoma*) and forest-edge thickets of bamboo and *Brocchinia* scrub near tree-line.

**Food and Feeding.** Little published. Feeds on various insects and other arthropods. Forages in pairs or singly, mostly 1-5 m above ground, sometimes to canopy of stunted low forest, progressing deliberately by short hops separated by pauses of up to several seconds to scan for prey. Reaches out, up or down, or lunges to glean prey from all leaf, stem, vine and branch surfaces with quick stabbing motions of the bill. Occasionally joins mixed-species flocks, but more often alone.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tepuis EBA. Uncommon to locally common. There are large numbers of specimens from the slopes of several tepuis in S Bolívar (e.g. Aprada, Chimantá, Jaua, Uaiján, Uei), indicating substantial populations in those areas. Owing to the largely inaccessible nature of the region, the tepuis have been little affected by human disturbance, and upper-elevation floras and faunas remain relatively pristine. Nevertheless, these ecosystems are considered highly sensitive to disturbance, and threats from uncontrolled burning and gold-mining do exist. A number of national parks, e.g. Canaima, Jaua-Sarisariñama and Duida, in Venezuela, and Pico da Neblina, in Brazil, protect (at least on paper) large parts of the Tepuis EBA and, moreover, all lands above 800 m lying S of R Orinoco in Venezuela were recently declared national monuments, effectively placing almost entire range of this species within the protected-area system.

**Bibliography.** Braun *et al.* (2003), Cory & Hellmayr (1924), Hilty (2003a), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Parker (2003a), Phelps & Phelps (1947, 1963), Ridgely & Tudor (1994), Robbins (2003a), Sick (1993), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Willard *et al.* (1991), Zimmer (2003a).

## 42. Variable Antshrike

### *Thamnophilus caerulescens*

**French:** Batará bleuâtre **German:** Südlicher Tropfenameisenwürger **Spanish:** Batará Variable

**Taxonomy.** *Thamnophilus caerulescens* Vieillot, 1816, Paraguay.

Relationships uncertain; has been treated as forming a superspecies with *T. amazonicus*, but such a relationship considered unlikely. Complex plumage variation and unusual geographical distribution suggest that this species is a prime candidate for systematic study. Other described races seem indistinguishable or have plumage differences that appear to be clinal; thus, *subandinus* (N Peru) synonymized with *melanochrous*, *connectens* (EC Bolivia) with *dinellii*, *albonotatus* (EC Brazil) with nominate, and *pernambucensis* (NE Brazil) with *cearensis*. Documentation needed in order to establish whether any parapatry without intergradation exists among races listed below. Eight subspecies recognized.

#### Subspecies and Distribution.

*T. c. melanochrous* P. L. Selater & Salvin, 1876 - E slope of Andes in Peru (from Amazonas S of R Marañón S to N Puno).

*T. c. aspersiventer* d'Orbigny & Lafresnaye, 1837 - SE Peru (SE Puno) and WC Bolivia (N slope in La Paz, Cochabamba and Santa Cruz).

*T. c. dinellii* Berlepsch, 1906 - EC & S Bolivia on S & E Andean slopes (Santa Cruz S to Tarija), and NW Argentina (E slope from Jujuy S to La Rioja and, at lower elevations, E to Formosa and S to N Córdoba and Santa Fe).

*T. c. paraguayensis* Hellmayr, 1904 - SE Bolivia (lowlands of Santa Cruz), NW & NC Paraguay (W of R Paraguay and, to E, in Concepción, Amambay and San Pedro) and S Brazil (Mato Grosso do Sul). *T. c. gilviger* Pelzelin, 1868 - NE Argentina (E of R Paraná except Misiones), extreme SE Brazil (E Paraná and SE São Paulo S to Rio Grande do Sul) and Uruguay.

*T. c. caerulescens* Vieillot, 1816 - SE Paraguay (E of R Paraguay except Concepción, Amambay and San Pedro), extreme N Argentina (Misiones), and N part of SE Brazil (Minas Gerais and SE Bahia S to W Paraná, W & NE São Paulo and Rio de Janeiro).

*T. c. ochraceiventer* Sneath, 1928 - EC Brazil (S Tocantins, Goiás, Distrito Federal, SC Bahia). *T. c. cearensis* (Cory, 1919) - NE Brazil (Ceará, Pernambuco, Alagoas).

**Descriptive notes.** 14-16 cm; 15-24 g. Male nominate race has forehead and crown black, side of head grey, upperparts dark grey, mixed with black on lower back, white inter-scapular patch; outer scapulars edged white, wing-coverts black spotted white, flight-feathers blackish-brown, edged pale brown and white; tail brownish-black, tips white; underparts grey, belly paler, often with suggestion of scalloping. Female has crown and upperparts olive-brown with clay-coloured tinge, inter-scapular patch weak or absent, uppertail coverts edged yellow-brown, wing-coverts very dark

brown, edged white on tips, wings dark brown with clay-coloured edgings, tail dark brown with small white tips; throat and upper breast ochraceous-grey, rest of underparts cinnamon-tawny, breast and sides tinged olive. Subadult resembles female but more buffy. Race *melanochrous* is distinctive, mostly black, variably mixed with grey on rump and lower underparts, white wing edges mostly confined to primaries, tail spots small, female with black crown becoming olive-grey on forehead and nape, wing-coverts spots very small, lower underparts cinnamon-tawny; *aspersiventer* differs from previous in having lower underparts

scalloped black and white, tail spots larger, female with crown dark olive-grey with blackish spots; *dinellii* is paler than nominate, flight-feathers yellow-brown, underparts vary in darkness anteriorly and extent of cinnamon posteriorly, some in N part of range ("connectens") having blackish feathers on throat and breast, no cinnamon on belly, female with crown and upperparts ochraceous grey, throat and upper breast light grey with faint yellow tinge, pale cinnamon posteriorly (approaches previous in coloration in N of range); *paraguayensis* is pale, lower underparts entirely white or tinged buff, female with crown olive-grey (blackish spots in W), wing-coverts olive-grey with blackish subapical spots (in E) and white tips, white below with variable yellowish-brown tinge; *gilviger* has flight-feathers edged clay colour, grey of throat and breast extending to upper belly, lower underparts washed cinnamon-tawny, female with throat to upper belly yellowish-grey, lower underparts cinnamon-tawny; *ochraceiventer* has upperparts and flight-feathers tinged clay colour, throat grey, remaining underparts greyish ochraceous, female with black crown mixed with olive-grey on forehead; *cearensis* has less black on crown and upperparts, female with crown rufous, wing-coverts ochraceous olive-brown (edges brightest), tail tinged clay colour, throat pale ochraceous. **VOICE.** Loudsong a simple countable series of usually 6-7 plaintive, evenly spaced whistles of same pitch and intensity (rarely, introductory or final notes differ slightly in pitch or intensity), note shapes and pace variable, perhaps regionally. Call a single note, usually short and nasal, typically repeated in long sequences but at highly variable pace; also longer, softer note and raspy growl.

**Habitat.** Understorey and mid-storey of evergreen forest, second-growth woodland, and patches of thickets and trees in open regions. More a bird of forest edge, open viny woodland and dense thickets than of mature forest interior, and often persists in highly degraded remnant patches. In N part of Andean range (*melanochrous*, *aspersiventer*) inhabits thickets and undergrowth of humid forest, also dense stunted forest on low-elevation ridge crests, at 1200-2800 m; farther S in Andes and at lower elevations in NW Argentina (*dinellii*), found most often in dense undergrowth under patches of trees in woodlands of foothills and plains, especially in riparian scrubland and shrubby hillsides in canyons, at 200-2700 m. In the Chaco of Bolivia and Paraguay (*paraguayensis*) occupies patches of tall dense shrubs and low trees in riparian situations, as well as semi-deciduous scrub-forest, at 150-850 m. In NE Argentina, Uruguay and extreme SE Brazil (*gilviger*) restricted to thickest woods of all types, which most often found along banks of streams and in swampy areas, to 1050 m; farther N (*caerulescens*), especially common in vine-tangled zones of steep hillsides and also occurs in bamboo, vine tangles on streamside banks, dense second growth and, locally, *restinga* (low, dense, stunted forest off sandy beaches), to 1300 m. In the Planalto (*ochraceiventer*), inhabits gallery forest and small woodlots of the highlands, at 750-1350 m. In NE Brazil (*cearensis*) restricted to remnant patches of humid or semi-humid forest with abundant vines, to 850 m, and absent from immediately adjacent *caatinga* or dry-forest habitats.

**Food and Feeding.** Little published. Feeds primarily on insects, including moths and larval lepidopterans, katydids (Tettigoniidae), grasshoppers (Acrididae), mantids (Mantidae), stick-insects (Phasmatidae), true bugs (Hemiptera, Homoptera) and beetles (Coleoptera), as well as spiders and other arthropods; also seeds. A pair in Brazil (Rio de Janeiro) seen to consume three melastome (*Melastoma*) fruits; the birds severed the fruit at the base, swallowed it, then spat out what appeared to be a papery skin or husk. Also observed feeding on berries of mistletoe (Myrsinaceae). Forages in pairs or singly, 1-8 m above ground (mostly 1-5 m), often in more open situations than other antshrikes, but also working dense crowns of bamboo where these form interlacing mats of vegetation with crowns of understorey trees. Great individual variation in pace of foraging; often progresses deliberately by short hops separated by pauses of 3-15 seconds (typical of most antshrikes), but more frequently moves steadily and somewhat rapidly (pauses seldom more than 1-2 seconds) with series of small hops (none more than a few centimetres), looking about constantly and changing direction more frequently than most congeners; regardless of pace, seems to spend long periods of time thoroughly covering small areas. Reaches out, up or down, or lunges to glean prey from all leaf, stem, vine and branch surfaces, using quick bill-stabbing motions; also regularly makes short (15-40 cm) jumping horizontal or downward strikes to pluck items from tops of leaves, and vertical sallies of up to 1 m to hover-glean from underside of overhanging vegetation. Often creeps up lianas and investigates them for food. Occasionally forages less than 1 m from ground, usually clinging laterally to slender vertical stems and then pouncing on arthropods in leaf litter, before jumping back up to a perch to scan. Sometimes hops about slowly on ground, peering around. While foraging, habitually flicks wings and dips the tail slowly before rapidly flicking it upwards (applies to nominate, *dinellii*, *gilviger* and *cearensis*; no data on other races). Often joins mixed-species flocks, but just as frequently alone. Nominative race occasionally reported as following army ants (both *Eciton burchelli* and *Labidus praedator*).

**Breeding.** Oct-Feb in Brazil, Aug-Nov in Bolivia and Peru and Oct-Dec in Argentina. Nest of *dinellii* a well-woven cup, diameter 6 cm, depth 5 cm, made of fine grass leaves, stems and stalks, lined with thinnest stalks and horsehairs or similar fine rhizomorphs, suspended by rim (connecting points additionally bound by spider webs) from thin branches of horizontal fork 0.6-2.5 m above ground in bush; nests in Argentina (*gilviger* and nominate race) similar; one nest of nominate race in E Brazil (Espírito Santo) a pendant cup 8 cm high, 10 cm across, covered on outside with moss, some hanging 7.5 cm below nest, placed 1.8 m up in a *Tibouchina* bush at edge of road in tall second growth; in NE Brazil (*cearensis*) a deep purse-shaped cup, loosely woven (contents visible from below) with coarser grasses and plant fibres, lined with fine black, horsehair-like rhizomorphs, frequently green leaves or moss woven into exterior, suspended by rim from thin horizontal fork (fibres of nest looped over branches at three obvious points of attachment) among foliage in understorey sapling or broad-leaf shrub, often with overhanging large leaf a few centimetres above rim, 6 nests 0.7-7.5 m above ground. Clutch size known for nominate race, *cearensis*, *dinellii* and *gilviger*, normally 3 eggs, less often 2, creamy white with irregular (and individually variable) purplish-brown blotches, speckles, occasional streaks, sometimes also ash-grey spots (Argentina), markings mostly concentrated around larger end; incubation by both sexes during day, both also feed chicks, no information on incubation and nestling periods; Espírito Santo nest (nominate) held an apparently infertile egg and a nestling, egg pinkish-white with large red-brown

spots on larger end, a few elsewhere, male gradually left care of single nestling to the female. Nest sometimes parasitized by Shiny Cowbird (*Molothrus bonariensis*) in Argentina.

**Movements.** Ringing at a site in N Argentina (Salta) suggests some movement in S; presumed resident throughout remainder of range.

**Status and Conservation.** Not globally threatened. Fairly common over most of its extensive range, which includes a number of protected areas. This species' adaptation to edge habitats, second-growth woodland and other human-created habitats makes it less sensitive to disturbance. In Brazil, in a study of remnant woodland patches in Paraná which ranged in size down to 0.5 ha, this was the only antbird to survive in all 13 patches; similarly, it was the only thamnophilid among the most frequently observed bird species surviving in a eucalyptus (*Eucalyptus*) plantation in Minas Gerais. In NE Brazil, however, the conservation of race *cearensis* is of concern, since humid forest within its range has been largely reduced to remnant patches (e.g. Murici Ecological Reserve and Pedra Talhada State Park, in Alagoas) surrounded by sugar cane and other large-scale agricultural development. One stronghold of this race is the Serra de Baturité

region, which has been categorized as a Secondary EBA (Ceará Caatinga and Serras) and is home to two restricted-range species, the Ochraceous Piculet (*Picumnus limae*) and the Buff-breasted Tody-tyrant (*Hemitriccus mirandae*), that are classified as Vulnerable. The few remaining areas of humid and semi-deciduous forest habitats in the Baturité region are still being cleared, and are in need of protection.

## Genus *PYGIPTILA* P. L. Sclater, 1858

### 43. Spot-winged Antshrike

#### *Pygiptila stellaris*

**French:** Batará étoilé **German:** Fleckenflügel-Ameisenwürger **Spanish:** Batará Estrellado

**Taxonomy.** *Thamnophilus stellaris* Spix, 1825, Pará, Brazil.

Relationships uncertain. Genetic studies indicate that genus is not closely related to *Thamnophilus*, but perhaps closest to the "stipple-throated assemblage" of *Myrmotherula* antwrens; it is, nevertheless, maintained in its traditional position in the taxonomic sequence, pending further study. Described plumage variation of forms *maculipennis* (S Colombia and NE Peru) and *purusiana* (W Brazil) appears to be clinal; these forms, therefore, merged with nominate, but further study required. Two subspecies recognized.

#### **Subspecies and Distribution.**

*P. s. occipitalis* J. T. Zimmer, 1932 - S Venezuela (W & S Bolívar, Amazonas), N Brazil (N Amazonas, Roraima, NW Pará) and adjacent extreme E Colombia, and NE & extreme S Guyana, coastal Surinam and, locally, W & C French Guiana.

*P. s. stellaris* (Spix, 1825) - extreme S Colombia (near base of Andes), E Ecuador and NE & E Peru E through S Amazonian Brazil (S to Rondônia, N Mato Grosso, S Pará, W Maranhão), and S to NW & NE Bolivia.

**Descriptive notes.** 12-13 cm; 23-27 g. Bill heavy; tail short; white interscapular patch. Male has black crown; otherwise grey, darker above, except for some black feathers on centre of back, white spots on wing-coverts. Female has crown, upperparts, tertials and tail grey, faintly tinged clay colour, especially on forehead, with remiges (except tertials) and wing-coverts cinnamon-tawny, head side and underparts pale clay colour, palest on throat, tinged grey on flanks and crissum; S of R Amazon, upperparts deeply tinged clay colour in W ("*maculipennis*"), becoming greyer, apparently clinally, to E. Race *occipitalis* is

darker than nominate, especially below, female with ochraceous forehead more clearly demarcated from grey crown. **VOICE.** Loudsong rather short (e.g. 1-2 seconds), uncountable series of evenly spaced abrupt notes, increasing in intensity and declining slightly in pitch, immediately followed by long whistle usually rising and falling slightly in pitch. Calls include sharp "chak", often intermixed with downslurred whistle which may be short (e.g. 0-3 seconds) and sharply downslurred (e.g. dropping from 5 to 2 kHz) or longer (e.g. 0-7 seconds) and flatter, pitch variable.

**Habitat.** Canopy and subcanopy of lowland evergreen forest, to 700 m. Occurs in both *terra firme* and seasonally flooded forest, and also in adjacent tall second growth, particularly in viny, leafy strata.

**Food and Feeding.** Feeds on variety of lepidopteran larvae, also orthopterans, particularly large katyids (Tettigoniidae), mantids (Mantidae), and stick-insects (Phasmatidae), beetles (Coleoptera), hemipteran bugs, and other insects; observed eating small frog. Forages in pairs, individually, or in family groups, moving actively along thin branches and through vegetation by short, heavy hops, frequently pausing for 1-2 seconds (occasionally to 10 seconds) to scan for prey; frequently puts on sudden burst of speed and scoots along branches or vines with series of closely spaced short hops; sometimes jumps into foliage clusters with beating wings as if to dislodge insects. Routinely hangs upside-down from tips of leafy outer branches or from dead-leaf clusters, sometimes for several seconds, clinging with feet and stretching neck to fullest extent to glean prey, sometimes spreading one wing and flattening it to the substrate for balance. In this manner, often probes curled dead-leaf clusters for several seconds at a time, sometimes tearing clusters apart with its bill; in 338 observations of feeding in Peru and Bolivia, dead leaves comprised 58% of foraging substrates, and same study indicated that dead-leaf foraging was height-dependent, with dead leaves searched more frequently when birds foraged in understorey and subcanopy than when in canopy. Also peers under branches in the manner of many tanagers (*Tangara*). Forages mostly 7-25 m above ground, concentrating on vine tangles, including clusters of hanging vines and philodendrons (*Philodendron*) along trunks, and terminal leafy branches, particularly on larger leaves; seems selectively to inspect leaves with obvious insect damage. Sometimes forages much lower (particularly in *várzea* or *igapó*), occasionally to near ground. Usually encountered in company of mixed-species flocks in mid-storey to canopy, although not considered a nuclear species of such flocks. Occasionally attends swarms of army ants (*Eciton burchelli*) passing through; then descends to near ground level.

**Breeding.** Little known. One previously unpublished description of nest-building in Brazil in Nov, also juvenile male following adult male in a flock in Nov, both in Belém area of Brazil; a nest in SE Peru in Sept. Nest built by both sexes, composed almost entirely of large leaves (some bigger than the bird) piled on top of one another (resembling a *Thamnomanes* nest), from the side appearing triangular in shape, lined with finer material (either roots or smaller leaves), placed c. 4-5 m above ground in mass of converging branches near top of small tree; building bird adds a leaf to nest, then sits in it to shape it.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Considered to be generally common throughout most of its extensive range. This includes a number of large parks and reserves in most countries in which it occurs: examples are Yapacana and La Neblina National Parks, in Venezuela, Amacayacu National Park, in Colombia, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve, Tambopata-Candamo Reserved Zone and Pacaya-Samiria National Reserve, in Peru, Serra do Divisor, Jaú and Tapajós National Parks, Cristalino State Park and Caxiuanã National Forest, in Brazil, and Madidi National Park, in Bolivia. Range also encompasses extensive, intact habitat which, although not formally protected, is at little short-term risk of development.

**Bibliography.** Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a, 2003b), Isler, P.R. & Whitney (2002), Munn & Terborgh (1979), O'Neill & Pearson (1974), Oniki & Willis (1983b), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Remsen (2003b), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg (1997), Schubart *et al.* (1965), Sibley & Ahlquist (1985), Sick (1993), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tallman & Tallman (1994), Terborgh *et al.* (1990), Thiollay (1994), Tostain *et al.* (1992), Willis (1984d), Zimmer, J.T. ## Genus *NEOCTANTES* P. L. Sclater, 1869

### 44. Black Bushbird

#### *Neoctantes niger*

**French:** Batará des fourrés **German:** Schwarzer Bodennameisenwürger **Spanish:** Batará Arbustero

**Taxonomy.** *Xenops niger* Pelzeln, 1859, Marabitanas, Amazonas, Brazil.

Relationships uncertain. Monotypic.

**Distribution.** Extreme SC & E Colombia (Putumayo, Vaupés, N Amazonas), E Ecuador, N & SE Peru (N Amazonas, Loreto, Cuzco, Madre de Dios) and W Amazonian Brazil (extreme NW & SW Amazonas, W Acre; also isolated records from W bank of middle R Madeira and W Pará).

**Descriptive notes.** 15-16 cm; 29-32 g. Lower mandible upturned; white interscapular patch. Male is entirely black. Female is sooty black, with rufous on breast, side and central upper belly. **VOICE.** Loudsong = countable (e.g. rate of 9 notes in 5 seconds) series of short, slightly upslurred whistles, all identical and at same pitch, although initial note often softer, duration highly variable, usually 15 or more notes but sometimes continuing for several minutes; male and female sometimes sing simultaneously, with female immediately after male, possibly a duet. Call distinctive, squealing, two-parted but continuous, with

second part lower-pitched.

**Habitat.** Understorey of lowland evergreen forest and adjacent second growth, to 750 m. Occurs in both *terra firme* and *várzea* forest (probably more common in latter), particularly in dense undergrowth around treefalls, light-gaps, and along swampy forest streams that are rank with *Heliconia*, ferns, fallen logs, sawgrass and viny thickets.

**Food and Feeding.** Little published. Assumed to feed on various insects, perhaps also other arthropods. Most witnessed prey captures have involved items too small to be identified; a male in Brazil was seen to extract a large, pale cricket (Gryllidae) from inside a suspended, curled dead leaf. Pairs or individuals forage in dense thickets, 0-10 m above ground, progressing by short hops, separated by pauses of 2-10 seconds to scan; advances through vine tangles, often hitching sideways, sitting with the body positioned perpendicular to the limb or vine, and with fairly upright posture. Occasionally probes in suspended, curled dead leaves, but most surface manoeuvres involve picking at vine and branch surfaces (not seen to pick at live leaves). Regularly employs subsurface foraging techniques, using the bill to hammer repeatedly at a branch, woody vine, palm rachis or rotten log until a hole is opened; then uses the uniquely shaped bill as a wedge to pry loose strips of live bark or stem fibres, or to flake off dead bark, afterwards picking repeatedly at small subsurface prey, which are swallowed without special manipulation. Frequently remains at a single station for 10 minutes or more. May occasionally associate loosely with mixed-species flocks passing through its territory.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. A low-density species that is not well known; considered rare to locally uncommon throughout its range. Its secretive nature, coupled with its preference for dense light-gap vegetation, makes it easily overlooked in anything other than intensive surveys; its abundance may, therefore, be generally underestimated. Much of the range of this species is relatively inaccessible, with vast areas of intact habitat, including in such protected areas as Yasuni National Park, in Ecuador, Serra do Divisor and Jaú National Parks, in Brazil, and Manu National Park and Biosphere Reserve, in Peru.

**Bibliography.** Álvarez (1994), Cory & Hellmayr (1924), Hilty (2003b), Hilty & Brown (1986), Isler & Whitney (2002), Parker (2003a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Stotz *et al.* (1996), Tallman & Tallman (1994), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Zimmer, J.T. (1931a), Zimmer, K.J. (2003a).

## Genus *CLYTOCTANTES* Elliot, 1870

### 45. Recurve-billed Bushbird

#### *Clytoctantes alixii*

**French:** Batará à bec retroussé

**German:** Grauer Bodennameisenwürger

**Spanish:** Batará Piquicurvo

**Taxonomy.** *Clytoctantes alixii* Elliot, 1870, "Rio Napo, Ecuador"; presumed error, locality unknown.

Relationships uncertain. Specimens on which original description was based were apparently labelled from "Equateur", but there is no satisfactory evidence that the species has ever occurred in Ecuador. Monotypic.

**Distribution.** NW Venezuela (Sierra de Perijá) and N Colombia (N end of the three main Andean ranges in César, Córdoba, Bolívar, Antioquia and Santander; one record from E slope of middle C range in Caldas).

**Descriptive notes.** 16-17 cm. Lower mandible strongly upturned; white interscapular patch. Male is dark grey, with loreal region, throat and centre of upper breast black, flight-feathers brownish-black, wing-coverts with tiny pale tips. Female has crown and upperparts dark rufous-brown, blackish on wings and tail, small pale rufous tips of wing-coverts, underparts reddish-brown, darker on flanks and crissum. Subadult male is dark yellowish and blackish-brown, forehead, head side and throat reddish yellow-brown, wing coverts dotted white. VOICE. Very little known. In Colombia, a female was recorded as giving a chirring

"ke'e'e'ew", reminiscent of voice of *Phaenostictus mcleannani*.

**Habitat.** Understorey of evergreen forest, forest edge, adjacent second growth, and regenerating clearings, apparently primarily in foothills; Venezuelan records between 300 m and 1200 m, Colombian records from 200 m to 1150 m. Seemingly favours dense vine tangles and thickets near the ground, as in treefalls, overgrown clearings and forest borders.

**Food and Feeding.** Almost nothing known. Among the few observations are one of a bird attending an army-ant swarm, and another of an individual stripping strands from dead stems in search of insects.

**Breeding.** Virtually nothing known. In W of range, breeding reported to occur in Apr-May.

**Movements.** Presumed resident.

**Status and Conservation.** **ENDANGERED.** Restricted-range species; present in Nechi Lowlands EBA and Colombian East Andes EBA. Known from only a few localities, with no records since 1965. Political instability throughout range in which it occurs has prevented any recent surveys; such surveys are urgently needed in order to assess current distribution and population size, as well as habitat requirements. The regions from which this species has been recorded have suffered extensive deforestation in recent decades, primarily for human settlement, cattle-ranching, and coca production, but there is some indication that it may survive and/or thrive in dense second growth. Two existing large national parks, Sierra de Perijá National Park, in Venezuela, and Paramillo National Park, in Colombia, could conceivably harbour populations of this species.

**Bibliography.** Avelado & Pons (1952), Carriker (1955), Chapman (1917, 1926), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Cory & Hellmayr (1924), Haffer (1975), Hilty (2003a), Hilty & Brown (1986), Meyer de Schauensee & Phelps (1978), Phelps & Phelps (1963), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stiles *et al.* (1999), Stotz *et al.* (1996), Willis (1988b).

## 46. Rondonia Bushbird

### *Clytoctantes atrogularis*

**French:** Batara du Rondonia

**Spanish:** Batará de Rondonia

**German:** Mato Grosso-Bodenameisenwürger

**Taxonomy.** *Clytoctantes atrogularis* Lanyon *et al.* 1990, Cachoeira Nazaré, Rondônia, Brazil.

Relationships uncertain. Monotypic.

**Distribution.** Rondônia, in SW Amazonian Brazil; known only from the type locality, on W bank of R Jiparaná.

**Descriptive notes.** 17 cm; 31 g. Lower mandible strongly upturned; bill very heavy. Male is entirely black. Female has anterior upperparts and auriculars chestnut, interscapular patch white, remaining upperparts brown, becoming grey on uppertail-coverts; remiges dark greyish-brown, edged chestnut-brown, wing-coverts dark chestnut with paler edges, tail black; throat, malar region and upper breast black, lower breast, sides and belly light chestnut, flanks grey with chestnut tips, crissum grey. VOICE. Male said to deliver a very loud, trilled whistle, "tree-tree-tree", at irregular intervals.

**Habitat.** Lowland humid *terra firme* forest dominated by dense vine tangles.

**Food and Feeding.** Little information available. Only two observations: first was of a male c. 1 m above ground in area of large treefall, where it worked up to 2-5 m in a vine tangle, pounding and digging at vines with its bill; second, brief observation was of a male 4 m up in a dense vine tangle.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** **CRITICAL.** Known from only a single adult female specimen and sightings of two males in the same area, all in 1986. Since only one individual was mist-netted during 1450 net-days and only two others were seen during 1400 hours of fieldwork by five experienced observers, this species is presumably very rare and local; an additional 375 net-days and 250 field hours at a similar site 70 km away produced no further observations. Systematic survey work in Rondônia (and adjacent areas of Amazonas and Mato Grosso) is urgently needed in order to locate any additional sites where this species may occur. Deforestation in this part of Amazonia is currently proceeding at a rate of some 4000 km<sup>2</sup> per year, placing this and other Rondônia endemics at extreme risk. Subsequent to the discovery of this bushbird, a hydro-electric dam was constructed at the type locality.

**Bibliography.** Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Lanyon *et al.* (1990), Ridgely & Tudor (1994), Sick (1993), Stattersfield & Capper (2000), Stotz *et al.* (1996), Zimmer, Parker *et al.* (1997).

## Genus *MEGASTICTUS* Ridgway, 1909

### 47. Pearly Antshrike

#### *Megastictus margaritatus*

**French:** Batara perlé

**German:** Kurzschnanz-Ameisenwürger

**Spanish:** Batará Perlado

**Taxonomy.** *Myrmeciza margaritata* P. L. Slater, 1855, Chamicuro, Loreto, Peru.

Relationships uncertain. Monotypic.

**Distribution.** Locally in S Venezuela (SW Bolívar, S Amazonas), extreme E & S Colombia (Guainía, Vaupés, Caquetá), E Ecuador, NE & EC Peru (Loreto, Ucayali) and WC Amazonian Brazil (NW & SC Amazonas, N Rondônia).

**Descriptive notes.** 12-13 cm; 18-21 g. Male has crown and upperparts grey, wings and tail black, wing-coverts and tertials with large rounded spots at tips, uppertail-coverts and tail tipped white; underparts pale grey, whitest on chin, throat and centre of belly. Female has crown and upperparts yellowish-brown, crown tinged blackish, wing-coverts, tertials, tail-coverts and tail spotted like male except spots pale buffish, flight-feathers edged ochraceous, underparts ochraceous with cinnamon tinge, palest on throat and centre of belly. VOICE. Loudsong 2-3 slowly delivered whistles, slurred up and down, followed by 6-7 flat raspy

notes at much faster pace, total length c. 2-5-3 seconds. Call whistled, upslurred "wheet" notes, repeated in groups of 2-3, as alarm or as contact between mates; also a hard rattle in agonistic situations.

**Habitat.** Understorey of lowland evergreen forest and adjacent older second-growth woodland, mostly below 500 m; to 1250 m in tepui region of S Venezuela. Probably more common in regions with sandy soil. Also noted along edges of lagoons.

**Food and Feeding.** Little published. Feeds on insects, including adult and larval lepidopterans, katydids (Tettigoniidae), grasshoppers (Acrididae), mantids (Mantidae) and stick-insects (Phasmatidae), as well as other arthropods, such as spiders. Forages in pairs, singly, or in family groups (up to 4 individuals), 1-10 m above ground, mostly at 2-6 m, clinging laterally to slender vertical stems or sitting upright on more horizontal branches; frequently swings tail from side to side in somewhat jerky, pendulum-like motion, or flicks it rapidly upwards in arc of 30-45 degrees, and occasionally flicks the wings. Progresses by a series of short hops of 7-30 cm in rapid succession, separated by pauses of 2-30 seconds to scan for prey. Prey taken primarily by three methods: diagonal sally-gleans of 1-5-4 m, usually upward-directed to underside of a green leaf, and then continuing on to another perch without stopping (75% of all manoeuvres recorded); aerial sallies to take flying prey in mid-air, again continuing on to another perch; and hover-gleans, involving a vertical sally to underside of overhanging vegetation and fluttering briefly to glean items. Foraging methods much like those of *Thamnomanes* antshrikes. When actively hopping (as opposed to pausing at scanning stations), also commonly lunges or pounces to glean prey, usually from upper surfaces of leaves. Sometimes associates loosely with mixed-species flocks.

**Breeding.** Nothing published. Nesting recorded in Aug in Brazil. A nest in Brazil (Borba, in Amazonas) was an open cup with diameter 8 cm externally, 5-7 cm internally, outside depth at shallowest end 6 cm, at deepest end 11 cm, loosely woven (contents visible from below) from plant fibres, rootlets, some twigs and numerous dead leaves, suspended by rim with plant fibres and spider webs (three points of attachment) from diagonal fork 65 cm up in understorey sapling; at bottom of cup two large dead leaves were woven in and left hanging, giving appearance of messy organic debris lodged in the sapling fork, and another mass of dead leaves formed a canopy several centimetres above cup. Clutch 2 eggs, creamy white, with variable amounts of maroon-brown blotching, streaking and network of lines heavily concentrated at larger end; male observed incubating at midday.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. A low-density species that is seemingly rare to locally uncommon at most locations throughout its range. Distribution appears to be somewhat patchy, with numerous records from a few widely scattered areas, such as Lagarto (upper R Ucayali, in Peru), Borba (Brazil) and São Gabriel da Cachoeira (upper R Negro, in Brazil), yet no records from many similar areas in between. Appears to survive, although at lower densities, in partially logged areas. Existence of vast areas of relatively inaccessible, intact, and seemingly suitable habitat should guarantee that this species is not at risk. Almost nothing is known of its ecological requirements and micro-habitat preferences, however, nor are the reasons for its apparent rarity and patchy distribution understood. Efforts should be made to fill in these gaps, thereby allowing more informed assessment of its true numerical status and conservation priorities for the species.

**Bibliography.** Álvarez (1994), Alverson *et al.* (2001), Cory & Hellmayr (1924), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Johns (1991), Paz y Miño (1989), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Sick (1993), Stotz *et al.* (1996), Whitney & Rosenberg (1993), Zimmer, J.T. (1932c), Zimmer, K.J. (2003a).

## Genus *XENORNIS* Chapman, 1924

### 48. Speckled Antshrike

#### *Xenornis setifrons*

**French:** Batará masqué

**German:** Strichelrücken-Ameisenwürger

**Spanish:** Batará Moteado

**Other common names:** Speckle-breasted/Spiny-faced Antshrike, Grey-faced Antshrike/Antbird

**Taxonomy.** *Xenornis setifrons* Chapman, 1924, Tacarcuna, 2050 ft [c. 625 m], Darién, Panama.

Relationships uncertain; possibly closest to *Thamnomanes* or *Megascictus* species on basis of similarities of posture, tail movements, foraging behaviour within mixed-species flocks, and some vocalizations. Monotypic.

**Distribution.** E Panama (E from Colón) and extreme NW Colombia (Chocó).

**Descriptive notes.** 15-16 cm; 25 g. Male is olive-brown above, all but rump feathers edged blackish, giving spotty appearance; wings dark brown, spotted and edged light reddish yellow-brown; tail blackish-grey, tips of outer rectrices paler; forehead, side of head and underparts dark grey, spotted pale grey on throat and breast. Female has upperparts like male but slightly paler, forehead like crown, side of head brown with lighter spotting, throat whitish-olive with blackish-brown spots; underparts light olive-brown, breast feathers with blackish edgings giving spotty appearance, flanks and crissum darker.

**Voice.** Male loudsong a short, countable series (e.g. 9 notes, 2-8 seconds) of whistles, rising in pitch in even steps, notes at both ends of series weaker and shorter, little space between notes; female loudsong shorter, lower-pitched, rising less in pitch. Call a series of 2-5 loud, abrupt "chak" notes repeated rapidly, occasionally given singly.

**Habitat.** Understorey of undisturbed wet and humid lowland and foothill evergreen forest, at 150-800 m, mostly above 350 m. Found mainly on flat areas at bottoms of ravines with semi-open canopy, many epiphytes and lianas, and dense understorey that often contains many palms; also occasionally on steep slopes below ridges.

**Food and Feeding.** Feeds on various insects and other arthropods. In Nusagandi region of Panama, typically encountered as closely associated pair-members, usually with mixed-species flocks of which other core members include *Myrmotherula axillaris* and *M. fulviventr* and Tawny-faced Gnatwren (*Microbates cinereiventris*). May function as a flock-leader within mixed flocks, in manner of *Thamnomanes* antshrikes (tape playback of its voice attracts other species in locations where present species is known to occur). Forages mostly 0.5-2.5 m above ground, sometimes as high as 5 m, perching on thin vertical stems and vines as well as horizontal perches, often in fairly open areas, from where it scans for prey; scanning periods 2-60 seconds, usually c. 20 seconds between perch changes. Attack manoeuvres are various types of sally to live vegetation, typically laterally or upward-directed and less than 1 m in distance, but occasional sallies of 2 m or more. Prey most often gleaned from tips and upper surfaces of leaves, particularly of palms.

**Breeding.** Two nests found in May in Panama (San Blas). Both cup-shaped, external measurements 11-12 cm deep, 14 cm wide, constructed entirely of rootlets and looking from outside like tangled mass, the rim bound to branch fork 2-8-3 m up in tree (one tree 3-5 m tall, other 9 m tall) at edge of stream in steep ravine adjacent to dense tangle (possibly resulting from landslide). Clutch probably 2 eggs, lilac, heavily marked with fine dark purple scrawls, broad ring of deep purple on wider end; one nest apparently preyed upon, at the other the two nestlings were fed by both parents, food including green lepidopteran larvae.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Darién Lowlands EBA. Recorded rarely and from just a few localities within a relatively tiny range. The only documented Colombian records are from one locality beside R Baudó, on lower slopes of Serranía de Baudó, in 1940. In Panama, most records since 1980 have come from just a few sites, particularly from Cerro Jefe and Cerro Azul (Panamá), from the 40,000-ha forest reserve centred around the Kuña Indian Reserve at Nusagandi (San Blas), where the species was judged to be fairly common but often inconspicuous, and from Cerro Pirre (Darién); also recorded from Chagres National Park and, probably, Portobelo National Park. While possibly long overlooked in some areas before its voice became known, the species does appear to have a genuinely patchy distribution. Much seemingly suitable habitat is assumed to be intact on both sides of the relatively undeveloped border between Darién and Colombia, particularly in Darién National Park (597,000 ha, also a World Heritage Site), Los Katios National Park (72,000 ha) and Ensenada de Utría National Park (c. 50,000 ha). Habitat also exists on the Caribbean slope of San Blas, but deforestation is severe and ongoing; unless determined measures are taken, it is likely that these forests will be cleared. Mining, completion of the Pan-American highway and human settlement considered the primary threats to the habitat. More surveys are needed in order to locate any additional populations of this antshrike, preferably within the large national parks noted above.

**Bibliography.** Adsett & Wege (1998), Álvarez-Cordero *et al.* (1994), Angehr & Jordan (1998), Christian (2001), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Dunning (1993), Engleman (1992, 1993), Hilty & Brown (1986), Isler & Whitney (2002), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Wetmore (1972), Whitney & Rosenberg (1993), Willis (1984e).

## Genus *THAMNISTES* P. L. Sclater & Salvin, 1860

### 49. Russet Antshrike

#### *Thamnistes anabatinus*

**French:** Batararousset

**German:** Rostbrauner Ameisenwürger

**Spanish:** Batará Café

**Taxonomy.** *Thamnistes anabatinus* P. L. Sclater and Salvin, 1860, Choctum, Alta Verapaz, Guatemala. Relationships uncertain. Races *gularis*, *aequatorialis* and *rufescens* possibly form a separate species; molecular and vocal analyses needed. Plumage differences between some races probably clinal. Seven subspecies recognized.

#### Subspecies and Distribution.

*T. a. anabatinus* P. L. Sclater & Salvin, 1860 - Atlantic slope of SE Mexico (E Oaxaca, Tabasco, Chiapas), Guatemala, Belize and Honduras.

*T. a. saturatus* Ridgway, 1908 - Nicaragua (Atlantic slope), Costa Rica (both slopes except NW Pacific) and extreme W Panama (W Chiriqui, W Bocas del Toro).

*T. a. coronatus* Nelson, 1912 - Panama (except extreme W) and NW Colombia (Atlantic slope in Córdoba).

*T. a. intermedius* Chapman, 1914 - Pacific slope in W Colombia and Ecuador.

*T. a. gularis* Phelps, Sr. & Phelps, Jr., 1956 - extreme NW Venezuela (Táchira), possibly extending into NE Colombia.

*T. a. aequatorialis* P. L. Sclater, 1862 - E Andean foothills in Colombia (except perhaps NE), Ecuador and extreme N Peru (N of R Marañón in N Amazonas).

*T. a. rufescens* Cabanis, 1873 - E Andean foothills from Peru (S of R Marañón) S to W & C Bolivia (La Paz, Cochabamba).

**Descriptive notes.** 13-15 cm (W of Andes), 15-16 cm (E of Andes); 19-23 g. Male nominate race has forehead, centre of crown and upperparts olive-brown, supercilium olive-yellow, line through eye dusky, auriculars pale olive-brown; interscapular patch cinnamon to orange-rufous; wings cinnamon-rufous, tail rufous; throat and underparts pale yellowish-olive, flanks and crissum olive. Female lacks orange interscapular patch. Races W of Andes have bill and body proportionately heavy, those E of Andes are slimmer and longer-tailed; *saturatus* is slightly darker than nominate; *coronatus* has crown rufescent, contrasting

with back, underparts yellow; *intermedius* differs from last in being slightly darker, interscapular patch with some blackish subapical spots; *aequatorialis* has crown very dark olive-brown, upperparts olive-brown, interscapular patch orange-rufous with black subapical spots, throat and side of head olive-yellow, underparts olive; *gularis* resembles last but throat less yellow, more ochre; *rufescens* has crown and upperparts paler, interscapular patch lacking black spots, supercilium, side of head and underparts bright ochraceous, lower underparts tinged olive. **Voice.** Loudsong W of Andes a short, countable series (e.g. 6 notes, 2 seconds) of abrupt downslurred notes that fall in pitch, preceded by abrupt lower-pitched softer note; E of Andes a short (e.g. 1-8 seconds) trill that mostly rises in pitch and slows down. Calls W of Andes include variable short, thin "weep" notes with pitch sharply rising and falling, strung together in doublets and triplets and in combination with downslurred squeal; also short harsh notes.

**Habitat.** Canopy and subcanopy of montane and nearby lowland evergreen forest, and adjacent tall second growth; also in transitional (semi-humid) forest in Pacific lowlands of Costa Rica (*saturatus*). Primarily in foothills, but some populations ranging down to sea-level; to 1700 m, mostly below 400 m in N (nominate).

**Food and Feeding.** Feeds mostly on insects, including beetles (Chrysomelidae, Cerambycidae, Curculionidae, Carabidae), true bugs (Hemiptera, including Pentatomidae), katydids (Tettigoniidae), crickets (Gryllidae), cicadas (Cicadidae) and bees (Apidae), and other arthropods, particularly spiders. Also observed eating fruit in canopy. Pairs or individuals forage mostly from mid-levels up to canopy (8-25 m above ground), but often lower, particularly at forest edge. Pair-members tend to forage unusually close together for a thamnophilid, almost always in the company of mixed-species subcanopy flocks of other insectivores, progressing by short hops at variable pace; sometimes very active, with almost no pauses, at other times more deliberate, pausing 1-5 seconds between hops. On flying to a new tree, often works its way up from mid-levels along hanging vines near the trunk, then takes a horizontal path out to slender terminal branches, before flying to another tree. Perch-gleans items from live leaves (particularly from top surfaces), stems and vines, using quick bill-stabbing motions and lunges, concentrating search in terminal outer foliage and in philodendrons (*Philodendron*) clinging to vertical trunks; frequently inspects leaf petioles, also frequently cranes its neck and leans (hanging by feet) to peer under leaves, sometimes hanging acrobatically like a tit (Paridae) from larger leaves; regularly inspects suspended, curled dead leaves (but also passes these by), delicately probing or, equally often, tearing them apart noisily with the bill. In Ecuador, frequently probes suspended clusters of moss, often by hanging over to reach them. An individual moving with a mixed-species mid-level flock in Costa Rica was observed to attend army ants (*Eciton burchelli*): it descended to 60 cm over periphery of swarm, and alternately hopped back and forth from a slender trunk to a hanging vine several centimetres away, working its way up to 3 m before flying to a nearby shrub 1 m above ground, opportunistically perch-gleaning or lunging for arthropods fleeing the ants, taking them from branches and the top surfaces of leaves; eventually worked up to 5 m above ground before flying away.

**Breeding.** Apr-Jun in Costa Rica. Nest built by both sexes, a deep cup composed mostly of dead leaves bound together by fine, dark fungal rhizomorphs, suspended by rim in horizontal fork, the points of attachment reinforced by spider webs or cocoon silk, 7-15 m up in tree at forest edge or in semi-open. Normal clutch 2 eggs, dull white, speckled with brown; both sexes brood and feed nestlings.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout its extensive range. No immediate threats have been noted, although the foothill/mid-elevation forests inhabited by this species throughout much of its range are under threat of deforestation for logging and agriculture, and it is conceivable that some races could be at risk if current trends continue.

**Bibliography.** Cody (2000), Cory & Hellmayr (1924), Foster *et al.* (1994), Greenberg & Gradwohl (1980), Hilty (1997, 2003a), Hilty & Brown (1986), Howell & Webb (1995a), Isler & Whitney (2002), Karr (1971a), Monroe (1968), Parker (2003a), Parker & Carr (1992), Rasmussen *et al.* (1996), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Schulenberg & Awbrey (1997a), Skutch (1969c, 1981), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Whitney (2003a), Whittaker (2003a), Willis (1984e), Zimmer, J.T. (1932f), Zimmer, K.J. (2003a).

# Genus *DYSITHAMNUS* Cabanis, 1847

## 50. Spot-breasted Antvireo

### *Dysithamnus stictothorax*

**French:** Batara tachet **German:** Fleckenbrustwürgerling **Spanish:** Batarito Pechipinto

**Taxonomy.** *Myothera strictothorax* [sic] Temminck, 1823, Bahia, Brazil. Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnophilus*, and morphological characteristics have connected it with *Thamnomanes*. Present species and *D. mentalis*, *D. striaticeps*, *D. puncticeps* and *D. xanthopterus* appear to form a monophyletic group to which other species placed in the genus are probably closely related. Monotypic.

**Distribution.** SE Brazil in coastal region from S Bahia S to Santa Catarina, extending inland in Minas Gerais (R Doce region) and São Paulo, and NE Argentina (Misiones).

**Descriptive notes.** 12 cm. Male has forehead and crown dark grey, auriculars blackish, white spots on side of head; upperparts greyish-olive, concealed white patch under scapulars; wings blackish, wing-coverts tipped white, flight-feathers broadly edged chestnut-rufous; tail rufous-olive, narrowly tipped white; throat and upper breast white, rest of underparts yellowish, greyer on sides, large dark spots on breast; iris reddish. Female differs from male in chestnut crown, more olive (less grey) upperparts, no white patch under scapulars, less spotting below. **VOICE.** Loudsong a series of rapidly delivered musical notes (e.g. 16 notes,

2-4 seconds) rising and falling in pitch, notes shorter and weaker at both ends of series (so that only longer notes in middle are easily countable); female song similar but shorter. Calls include short, upslurred "chirr", nasal "qwar", and a series of three notes with first two on same pitch.

**Habitat.** Understorey and mid-storey of lowland and montane evergreen forest, to 1250 m. Overlaps in many places with *D. mentalis*, but is seemingly more of a forest-edge bird, found frequently in roadside forest, older second-growth forest, and shaded light-gaps with dense thickets of bamboo (e.g. old landslide areas); replaced by that species in continuous primary forest. In some parts of range, replaced at higher elevations by *D. xanthopterus* (slight elevational overlap).

**Food and Feeding.** Little published. Feeds on insects, including adult and larval Lepidoptera, katydids (Tettigoniidae), mantids (Mantidae), stick-insects (Phasmatidae), true bugs (Hemiptera) and beetles (Coleoptera), also other arthropods. Observed also to feed on berries of mistletoe (*Rapanea*). Usually encountered as closely associated pair-members or as individuals, often associated with mixed-species flocks that include *D. mentalis* and *Drymophila* species. Moves constantly through vine tangles, bamboo thickets and crowns of understorey trees, 1-10 m above ground, often working vertically upwards on vines and stems; progresses by short, often wing-assisted hops, with pauses of up to several seconds to scan, mostly overhead. Twitches wings slightly but continuously while foraging. Very acrobatic, perch-gleaning prey from all surfaces but primarily undersurfaces of live foliage, and from stems, vines, thin branches and suspended dead leaves (particularly of bamboo), often stretching or hanging on leaves to reach substrates; nearly as frequently hover-gleans beneath overhanging vegetation, or makes short jumping sallies of several centimetres to pluck prey from undersides of leaves. Tendency to forage higher than *D. mentalis* where the two co-exist, although much overlap.

**Breeding.** Nest found in Brazil (Rio de Janeiro) in Dec, for which details previously unpublished: described as a small pendent cup or bag located c. 15 m off ground in fork of thin limb of tree over 25 m tall on steep slope in tall hilly forest.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Fairly common throughout most of its range; viable populations exist in some protected reserves, notably in Brazil's Itatiaia and Tijuca National Parks, and in several other areas that are not formally protected. This species survives well in selectively logged forest. As a whole, however, the region which it inhabits has suffered severe habitat loss through urbanization, logging and agriculture, and this and other species that are confined to it require monitoring.

**Bibliography.** Aleixo (1999), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1924), Gonzaga *et al.* (1995), Isler, M.L. & Isler (2003a), Isler, M.L. *et al.* (1998), Isler, P.R. & Whitney (2002), Machado (1999), Parker (2003a), Parker & Goerck (1997), Pineschi (1990), Remsen & Parker (1984), Ridgely & Tudor (1994), Schönwetter & Meise (1967), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Teixeira, Naeinovic & Marti (1993, 1994), Whitney (2003b), Zimmer (2003a).

## 51. Plain Antvireo

### *Dysithamnus mentalis*

**French:** Batara gorgeret **German:** Olivgrauer Würgerling **Spanish:** Batarito Cabecigrís

**Taxonomy.** *Myothera mentalis* Temminck, 1823, Curitiba, Paraná, Brazil.

Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnophilus*, and morphological characteristics have connected it with *Thamnomanes*. Present species and *D. stictothorax*, *D. striaticeps*, *D. puncticeps* and *D. xanthopterus* appear to form a monophyletic group to which other species placed in the genus are probably closely related. Racial divisions of present species somewhat tentative; some races may represent points on a cline of plumage variation, and in some areas (e.g. in Colombia and Peru) range delimitations therefore impossible to describe with certainty; molecular studies needed in order to establish relationships among populations. Eighteen subspecies recognized.

#### Subspecies and Distribution.

- D. m. septentrionalis* Ridgway, 1908 - Atlantic slope from SE Mexico (Campeche, Chiapas) E to Honduras, and both slopes in Costa Rica and W Panama (W of Canal).
- D. m. suffusus* Nelson, 1912 - both slopes in E Panama and extreme NW Colombia (N Chocó, N Antioquia).
- D. m. extremus* Todd, 1916 - W Colombia (W Andes and W slope of C range from S Antioquia, W Caldas and Risaralda S to Cauca).
- D. m. aequatorialis* Todd, 1916 - Pacific slope in W Ecuador and extreme NW Peru (Tumbes).
- D. m. viridis* Aveledo & Pons, 1952 - N Colombia (mountains from La Guajira S to N Santander) and W Venezuela (Sierra de Perijá and W portion of Andes in Zulia, Mérida and Táchira).
- D. m. cumbreanus* Hellmayr & Seilern, 1915 - N Venezuela (coastal mountains, Falcón and Lara E to N Sucre).
- D. m. oberi* Ridgway, 1908 - Tobago.
- D. m. andrei* Hellmayr, 1906 - NE Venezuela (S Sucre S to NE Bolívar) and Trinidad; presumably this race in W & S Guyana.
- D. m. ptaritepui* J. T. Zimmer & Phelps, Sr., 1946 - SE Venezuela (Ptari-tepuí and Sororopán-tepuí, in Bolívar).
- D. m. spodionotus* Salvin & Godman, 1883 - S Venezuela (S Bolívar, Amazonas) and extreme N Brazil (N Roraima).
- D. m. semicinereus* P. L. Slater, 1855 - WC Colombia from S Santander S to W Caquetá (E slope of C Andes, C & S portion of E range, and Macarena Mts).
- D. m. napensis* Chapman, 1925 - extreme S Colombia (E slope of Andes in Putumayo) S to extreme N Peru (N Amazonas).
- D. m. tambillanus* Taczanowski, 1884 - E slope in N & C Peru (E Piura, S Amazonas and SW Loreto S to Huánuco and W Ucayali).
- D. m. olivaceus* (Tschudi, 1844) - E slope in C Peru (Pasco S to Cuzco and W Madre de Dios).
- D. m. tavarae* J. T. Zimmer, 1932 - SE Madre de Dios S to C Bolivia (S La Paz, S Beni, Cochabamba, SW Santa Cruz).
- D. m. emiliae* Hellmayr, 1912 - NE Brazil (SE Pará E to Ceará and Paraíba, S to N Tocantins and Alagoas).
- D. m. affinis* Pelzel, 1868 - extreme NE Bolivia (NE Santa Cruz) and C Brazil (S Mato Grosso, N Mato Grosso do Sul, and S Tocantins S to S Goiás).
- D. m. mentalis* (Temminck, 1823) - EC & SE Brazil (E Bahia, S Minas Gerais and S Mato Grosso do Sul S to Rio Grande do Sul), E Paraguay and NE Argentina (Misiones).

**Descriptive notes.** 10-13 cm; 12.5-14.5 g (*septentrionalis*), 14-16 g (*extremus*, *tambillanus*), 13-15 g (*olivaceus*, *tavarae*), 12-14 g (*andrei*, *affinis*, *emiliae*), 11-13 g (*mentalis*). Male nominate race has forehead and crown dark grey, auriculars blackish; upperparts greyish-olive, concealed white interscapular patch; remiges, greater wing-coverts and tail dark greyish-olive, flight-feathers edged olive, greater coverts tipped white, tail narrowly tipped white; lesser and median coverts blackish, medians tipped white; throat and upper breast white, spotted light grey, sides olive-grey, centre of belly yellow, mixed with pale

grey on lower breast, flanks and crissum. Female differs from male in having crown cinnamon-tawny, upperparts and wings more olive (less grey), wing-covert tips and remex edgings olive-yellow, no white interscapular patch, yellow below more extensive. Races differ from nominate mainly in colour tones, most being greyer in male and browner in female: *viridis*, *cumbreanus* and *emiliae* resemble nominate; *septentrionalis* male is greyer with belly yellowish, female browner throughout; *suffusus* resembles previous but slightly paler; *affinis* is somewhat paler than last with belly centre white, female warm brown above; *andrei* is slightly darker grey and female duller brown than previous; *oberi* resembles last, female yellower below; *extremus* male has blackish crown; *semicinereus* has almost pure grey upperparts barely tinged olive, tail greyer, auriculars hardly darker than crown, throat and underparts grey, breast darker, belly centre white, lower belly and flanks light grey with faint yellow tinge, female crown more tawny, less grey above, wings and tail edged clay colour, throat tinged light olive-brown, breastband light olive-brown, contrasting white belly becoming pale yellowish-olive posteriorly, sides and flanks olive; *spodionotus* is darker than last, female warm ochraceous with white throat and belly; *ptaritepui* and *tavarae* are rather similar to last but less dark; *olivaceus* resembles previous but slightly more olive; *napensis* is paler than previous, has grey breastband; *tambillanus* is very like last; *aequatorialis* is much paler below than previous, belly pale yellow, flanks tinged grey, dark auriculars more contrasting. **VOICE.** A short (e.g. 2 seconds) series starting with a few (e.g. 4) evenly paced, countable notes at same pitch, notes then gradually becoming more abrupt and dropping in pitch, ending in accelerating roll. Calls include nasal, musical note, and distinctive short (e.g. 6 notes), rapid series of gradually rising notes. Vocal differences among races remain to be studied.

**Habitat.** In N of range and in Andes occupies understorey and mid-storey of humid, foothill and lower montane evergreen forest and nearby tall second growth, in some regions (e.g. W Ecuador, C Bolivia) extending to deciduous and semi-deciduous forest; generally at 600-2500 m, but to sea-level in some regions. In E & S found from sea-level to 1200 m: in moist *terra firme* and *várzea* forest and dry savanna forest in NE Brazil (*emiliae*), elsewhere in dry savanna forest, older second growth, semi-deciduous and viny forest, and gallery forest; also humid Atlantic forest (*mentalis*). Found at both forest edge and in interior. Replaces *D. puncticeps* at higher elevations in NW (Costa Rica S to W Ecuador).

**Food and Feeding.** Feeds on variety of insects, including adult and larval lepidopterans and beetles (Coleoptera), katydids (Tettigoniidae), true bugs (Hemiptera) and ants (Formicidae); also other arthropods, such as spiders. Observed also to feed on berries of mistletoe (*Rapanea*). Typically encountered as closely associated pair-members or as individuals, often with mixed-species flocks of woodcreepers (Dendrocolaptidae), foliage-gleaners (Furnariidae), antwrens, and greenlets (*Hylophilus*), but frequently independent of flocks. Forages from near ground to 4-5 m up, occasionally higher, rarely to lower canopy; constantly flicks both wings slightly as it forages. Moves are separated by long pauses to scan nearby surfaces; then jumps or sallies out in explosive flits to attack prey or to move to a new perch. Primarily a generalized perch-gleaner, taking prey directly from both surfaces of live leaves (mostly), vines (often) and thin branches, occasionally from dead leaves; less frequently, but regularly, makes short sallies to glean items from substrates, or hover-

gleans from undersides of leaves. Often forages by hopping upwards through vines where these present, and sometimes visits the ground to feed among roots and piles of branches. Occasionally follows swarms of army ants (both *Eciton burckellii* and *Labidus praedator*) for brief periods.

**Breeding.** Feb-Jul in Costa Rica, Apr-Jul in Trinidad, Nov in SE Brazil and Nov in N Argentina. Additional nest and egg descriptions from Colombia, Tobago and Paraguay. Nest a deep, thin-walled cup of dark fibrous roots, fungal filaments and/or herbaceous materials, exterior almost always at least partially covered with green moss, strands of which often extend as a sort of hanging "tail", and suspended by rim typically from horizontal fork of shrub or small tree 0.6-2.5 m above ground. Normal clutch 2 eggs, dull white (or pale cinnamon in SE Brazil), with purple or purplish-brown (brown in Tobago) spots and lines, usually heaviest at larger end; up to three replacement nests recorded, ringed female in Trinidad incubating on second nest only 12-15 days after clutch disappeared from first, and laid in third nest 26-28 days after loss of eggs in second; incubation 15 days, by both sexes during day; chick hatches naked, nestling period 9-10 days in Costa Rica; both sexes, when flushed from nest, drop straight to ground and engage in fluttering distraction displays, wings spread to reveal contrasting marginal coverts and outer webs of outer scapulars. A female in Trinidad documented as nesting 8 years after having been ringed as an adult.

**Movements.** None recorded; presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Generally fairly common throughout its extensive range. Occurs in several protected areas. In some areas, continuing deforestation could ultimately threaten some races. Survival rate in small remnant forest patches in SE Brazil has been found to be uneven, and appears to be adversely affected by selective logging.

## 52. Streak-crowned Antvireo

### *Dysithamnus striaticeps*

French: Batará strié

German: Streifenkopfwürgerling

Spanish: Batarito Estriado

**Taxonomy.** *Dysithamnus striaticeps* Lawrence, 1865, Angostura, Costa Rica.

Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphila*, and morphological characteristics have connected it with *Thamnomanes*. Present species and *D. stictothorax*, *D. mentalis*, *D. puncticeps* and *D. xanthopterus* appear to form a monophyletic group to which other species placed in the genus are probably closely related. Monotypic.

**Distribution.** Atlantic slope in extreme SE Honduras (S El Paraíso), Nicaragua (R San Juan) and Costa Rica (also barely spilling over to Pacific slope in Guanacaste).

**Descriptive notes.** 10-11 cm; 15-17 g. Male has forehead and crown dark grey, heavily streaked greyish-white, auriculars blackish; upperparts greyish-olive, with concealed white interscapular patch; remiges dark greyish-olive, broadly edged with buffy greyish, wing-coverts blackish, tipped white, tail dark greyish-olive, tipped white; throat and breast white with bold dark streaks, sides olive-grey, belly whitish, lower underparts tinged yellowish. Distinguished from *D. mentalis* by bold streaks on crown and underparts. Female differs from male in dark-spotted rufous crown, less black on wing-coverts, ochraceous breast

and flanks. Subadult male is like female, but upperparts greyer, underparts whiter. VOICE. Loudsong a long (e.g. 21 notes, 4-1 seconds) series in which notes initially rise in pitch and intensity, remain constant, then gradually shorten, weaken and descend in pitch, notes countable before coalescing into a roll. Calls include soft single or double whistles and short "chirr".

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest, to 900 m; more common in foothills than in lowlands. Sometimes ventures into adjacent older second-growth forest.

**Food and Feeding.** Little published. Feeds on insects, including orthopterans, true bugs (Hemiptera), adult and larval lepidopterans; also other arthropods, such as spiders. Usually encountered as closely associated pair-members or as individuals, most frequently associated with mixed-species flocks of woodcreepers (Dendrocolaptidae), foliage-gleaners (Furnariidae), antwrens, and greenlets (*Hylophilus*), usually 1.5-8 m above ground. Works deliberately through foliage, progressing by short hops, with brief intervening pauses to scan; most often in crowns of understorey saplings. Generalized gleaner of mostly live foliage (some dead leaves inspected), perch-gleaning prey from both surfaces of live leaves and from vines, stems and branches; frequently hover-gleans or makes short sallies to undersides of overhanging leaves.

**Breeding.** Mar-Jun in Costa Rica. Nest a thin cup of mostly dark horsehair-like fibres from stem of a woodland fern, often decorated on outside with green moss, which may trail down several centimetres from bulk of nest, attached by rim in slender horizontal fork usually 1.5-4 m above ground. Normal clutch 2 eggs, whitish, blotched and flecked with chocolate-brown or purplish-brown, heavily on larger end; incubation by both sexes, period at least 14 days; both sexes also brood and feed nestlings.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central American Caribbean Slope EBA. Fairly common to uncommon throughout its relatively small range. Although ongoing clearing of forest for agriculture is of concern throughout the region, this species has viable populations in a number of protected parks and reserves in Costa Rica, key areas including La Selva Biological Reserve and, particularly, Braulio Carrillo National Park.

**Bibliography.** Anon. ## 53. Spot-crowned Antvireo

### *Dysithamnus puncticeps*

French: Batará ponctué German: Tüpfelscheitelwürgerling Spanish: Batarito Coronipunteado

**Taxonomy.** *Dysithamnus puncticeps* Salvin, 1866, Calovévora, Veraguas, Panama.

Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphila*, and morphological characteristics have connected it with *Thamnomanes*. Present species and *D. stictothorax*, *D. mentalis*, *D. striaticeps* and *D. xanthopterus* appear to form a monophyletic group to which other species placed in the genus are probably closely related. Birds from S Panama and W Colombia described as race *intensus* and others from SW Colombia and W Ecuador as *flemmingi* on basis of darkness of plumage, but apparently intergrade broadly with each other and with other populations; racial subdivision considered unwarranted. Monotypic.

**Distribution.** SE Costa Rica (Limón), Panama (Caribbean slope, also Pacific slope in extreme E Panamá and Darién), W Colombia (Pacific slope, and lower Cauca Valley in Antioquia) and NW Ecuador (S to Los Rios and Manabí).

**Descriptive notes.** 11-12 cm; 15-17 g. Male has forehead to nape dark grey, heavily dotted white; upperparts greyish-olive, concealed white interscapular patch; remiges dark greyish-olive, broadly edged buffy greyish, wing-coverts blackish, tipped white, tail dark greyish-olive, tipped white; throat to upper belly white with dark streaks, sides olive-grey, lower underparts tinged ochraceous. Differs from *D. striaticeps* in having crown and nape dotted whitish rather than streaked, also streaks below paler, less distinct. Female differs from male in dark-spotted rufous crown to nape, pale buff head side, throat and central belly,

ochraceous rest of underparts, thinner streaks below, less black on wing-coverts. VOICE. Loudsong a rapid (e.g. 28 notes, 2-7 seconds) trill, notes not countable, pitch first rising slightly, falling slightly terminally, pace constant initially, then accelerating slightly towards end. Calls include short descending "chirr".

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest, to 1000 m. Replaced at higher elevations by *D. mentalis* throughout much of range.

**Food and Feeding.** Little published. Feeds on various insects, including small grasshoppers and relatives (Orthoptera), and other arthropods, including spiders. Usually in pairs or family groups, with individuals associating closely, frequently with mixed-species flocks of other insectivores, but perhaps a less faithful flock-follower than *D. striaticeps*. Forages mostly in crowns and upper strata of understorey trees, 3-8 m above ground, moving deliberately through branches by short hops, with pauses to scan; appears to have preference for somewhat open foliage where it can visually examine the surroundings. Frequently hover-gleans prey from undersides of overhanging leaves; also perch-gleans from mostly live foliage, or makes short upward-directed sallies to vegetation. Occasionally noted as following army ants (*Eciton burckellii*) for brief periods, typically only when mixed-species flock intercepts a swarm; then usually sticks to periphery of swarm in more open understorey, 1-6 m above ground (rarely descending to 0.5 m), and sallies to glean flushed arthropods from foliage, stems and branches.

**Breeding.** Apr-Jul in Panama; nest-building noted in late Aug in Colombia (upper Anchicayá Valley). A nest in Panama was a cup suspended by rim in horizontal fork 2 m above ground; 2 eggs; both sexes incubated during day. In another Panamanian study (Canal Zone), three monitored nests were all lost to predation.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Not well known; considered fairly common to uncommon throughout most of its range. Range encompasses some large protected areas, examples of which are Soberanía, Darién and Chagres National Parks and Comarca Kuna Yala Indigenous Reserve, in Panama, Ensenada de Utría and Los Katíos National Parks, in Colombia, and Bilsa Biological Station, in Ecuador. No immediate threats.

**Bibliography.** Anon. (1998a), Cory & Hellmayr (1924), Eisenmann (1952), Greenberg & Gradwohl (1980, 1985), Griscom (1927b), Gross (1927), Hilty (1997), Hilty & Brown (1986), Isler & Whitney (2002), Parker & Carr (1992), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgely (1991), Robinson *et al.* (2000), Schemske & Brokaw (1981), Schulenberg (1983), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Sturgis (1928), Wetmore (1972), Willis (1972b, 1980, 1984e), Willis & Eisenmann (1979), Zimmer (2003a).

## 54. Rufous-backed Antvireo

### *Dysithamnus xanthopterus*

French: Batará à dos rous

German: Rostrückenwürgerling

Spanish: Batarito Dorsirrufo

**Taxonomy.** *Dasythamnus xanthopterus* Burmeister, 1856, Nova Friburgo, Rio de Janeiro, Brazil. Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphila*, and morphological characteristics have connected it with *Thamnomanes*. Present species and *D. stictothorax*, *D. mentalis*, *D. striaticeps* and *D. puncticeps* appear to form a monophyletic group to which other species in the genus are probably closely related. Monotypic.

**Distribution.** Coastal mountains of SE Brazil from Rio de Janeiro S to Paraná.

**Descriptive notes.** 12 cm. Male has head and upper back grey, with forehead, side of head to above eye and lores spotted white; remaining upperparts rufous; centre of throat white; underparts pale grey, whitest on belly, with flanks ochraceous. Female is similar to male, but crown rufous, facial spotting and underparts pale buff, with sides and flanks pale olivaceous. VOICE. Loudsong is a rapid (e.g. 20 notes, 2 seconds), slightly accelerating trill, loudest initially (except for the first note), then gradually falling in intensity and pitch. Calls include a short, low-pitched muffled note slightly up and down in pitch, sounding

like "quock"; also a short, harsh bark.

**Habitat.** Mid-storey and subcanopy of montane evergreen forest and old second growth, at 750-1700 m.

**Food and Feeding.** Little published. Feeds on insects and other arthropods, including flies (Diptera), butterfly and moth larvae (Lepidoptera) and beetles (Coleoptera); observed also to feed on berries of mistletoe (*Rapanea*). Forages in pairs or individually, mostly 3-12 m above ground, particularly in extremities of mid-storey canopy-tree branches, crowns of bamboo, and woody vine tangles; progresses by short, often wing-assisted hops, separated by pauses of 1-3 seconds to scan for prey. Makes short (to 50 cm), jumping, upward-directed sallies to glean prey from undersides of overhanging vegetation, striking quickly, with little pause or fluttering before dropping back to lower perch; performs such manoeuvres more frequently than do congeners. Also perch-gleans, by reaching or lunging, from all leaf, stem, vine and branch surfaces, with quick bill-stabbing motions. Frequently follows mixed understorey flocks of furnariids and other thamnophilids; not observed at ant swarms.

**Breeding.** Little known. Season judged to be Sept-Feb. Single described nest: an open cup of thin plant fibres, surrounded by thick layer of hanging moss (apparently for camouflage), suspended by rim from horizontal fork 1.8 m above ground; contained 2 eggs, white, striped and spotted violaceous and brown, markings concentrated at larger end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Uncommon and locally distributed over a small area; as such, the species warrants continued monitoring. Viable populations exist in a few protected parks and reserves, among them Itatiaia National Park and Serra dos Órgãos National Park; also present in Serra do Mar State Park.

**Bibliography.** Cory & Hellmayr (1924), Isler & Whitney (2002), Luigi, Raposo & Schloemp (1996), Luigi, Schloemp & Raposo (1991), Parker (2003a), Pineschi (1990), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Whitney (2003a), Zimmer (2003a).

## 55. White-streaked Antvireo

### *Dysithamnus leucostictus*

**French:** Batará à points blancs

**Spanish:** Batarito Albilistado

**German:** Nördlicher Schwarzbrustwürgerling

**Other common names:** White-spotted Antvireo/Antshrike; Venezuelan Antvireo (*tucuyensis*)

**Taxonomy.** *Dysithamnus leucostictus* P. L. Slater, 1858, Rio Napo, Ecuador. Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphylus*, and morphological characteristics have connected it with *Thamnomanes*. Species was formerly treated as conspecific with geographically remote *D. plumbeus*, and incorrectly transferred to *Thamnomanes*. Race *tucuyensis* distinctive, and widely separated geographically from nominate; vocal and molecular studies may indicate it is a separate species. Two subspecies recognized.

#### **Subspecies and Distribution.**

*D. l. tucuyensis* Hartert, 1894 - N Venezuela (coastal mountains from Falcón and Lara to Monagas).  
*D. l. leucostictus* P. L. Slater, 1858 - E slope of Andes from C Colombia (S from Meta) S to extreme N Peru (N Amazonas, Cajamarca).

**Descriptive notes.** 12-13 cm; 20 g (*leucostictus*). Male is dark grey, blackest on breast, wing-coverts with white tips and narrow white edges; concealed white interscapular patch. Female is reddish-brown above; side of head, throat and underparts grey, spotted and streaked white, flanks and crissum tinged brown and unstreaked. Subadult male is rufous-tinged grey, wings rufous-brown, tail dark brown, throat spotted pale grey, underparts with thin white shaft streaks. Race *tucuyensis* male differs in having wing-covert edgings broader, bend of wing and outermost primary edged white, underparts paler, female is paler throughout, yellower above, spots below much larger, flanks and crissum olive. Voice. Loudsong nominate race a short (e.g. 6 notes, 1-8 seconds), easily countable series of strong whistles, pitch falling (except sometimes for initial note), first and last notes less intense; *tucuyensis* a moderately long (e.g. 13 notes, 2-7 seconds), barely countable series of strong whistles, pitch and intensity gradually rising to middle notes, then gradually declining.

**Habitat.** Understorey of montane evergreen forest; at 900-2000 m in Colombia to Peru, 500-1900 m in Venezuela.

**Food and Feeding.** Little published. Feeds on variety of insects and other arthropods. In Venezuela, typically encountered in pairs, either alone or, more frequently, associated with mixed-species understorey flocks; rarely found away from mixed-species flocks in W range (nominate). Typical flock associates include *D. mentalis*, *Myrmotherula schisticolor*, Olivaceous Woodcreeper (*Sittasomus griseicapillus*), Three-striped Warbler (*Basileuterus tristriatus*) and Slate-throated Redstart (*Myioborus miniatus*). In Venezuela, usually forages 1.5-4 m above ground, concentrating on leafier and more viny layers of understorey. Typical foraging pace more rapid than that of sympatric *D. mentalis*. Changes perches frequently, and often suddenly; a common manoeuvre is to fly from one tree to another and immediately flutter down a metre or more to a lower perch (making it harder to observe than many congeners). Otherwise, a generalized foliage-gleaner, taking prey by perch-gleans and in jumping upward-directed sallies to undersides of overhanging leaves, vines or branches. Frequently drops to the ground to pursue flushed prey, or to pounce on prey in leaf litter, sometimes spending several seconds before moving back to an above-ground perch.

**Breeding.** Nothing recorded.

**Movements.** None recorded; presumed resident in both parts of range.

**Status and Conservation.** Not globally threatened. Uncommon throughout much of its range. No immediate threats. In W, Andean foothill forests in general are being cleared for agriculture and human settlement at an alarming rate, and the status of taxa with restricted ranges could change rapidly; large protected areas that could serve as population reservoirs of nominate race include Podocarpus, Sumaco-Galeras and Sangay National Parks, in Ecuador. Henri Pittier National Park, in Venezuela, protects a sizeable population of *tucuyensis*.

**Bibliography.** Cory & Hellmayr (1924), Hellmayr & Seilern (1912), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schäfer & Phelps (1954), Schulenberg (1983), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Whitney (1992a), Zimmer, J.T. (1933a), Zimmer, K.J. (2003a).

## 56. Plumbeous Antvireo

### *Dysithamnus plumbeus*

**French:** Batará plombé

**Spanish:** Batarito Plomizo

**German:** Südlicher Schwarzbrustwürgerling

**Other common names:** Plumbeous Antshrike

**Taxonomy.** *Myiothera plumbea* Wied, 1831, south-eastern Brazil.

Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphylus*, and morphological characteristics have connected it with *Thamnomanes*. Species was formerly treated as conspecific with geographically remote *D. leucostictus*, and incorrectly transferred to *Thamnomanes*. Monotypic.

**Distribution.** SE Brazil from S Bahia S to E Minas Gerais and extreme N Rio de Janeiro.

**Descriptive notes.** 12-13 cm. Male is dark grey, blackest on breast, wing-coverts with white tips and narrow white edges; concealed white interscapular patch. Female is mostly olive-brown, two buff-white wingbars, throat very pale grey, lower underparts ochraceous. Voice. Loudsong a short (e.g. 4 notes, 1-3 seconds) series of moderately long whistles (notes longer than spaces between them), second note at higher pitch than first, the third and fourth notes declining in pitch, first and last notes less intense.

**Habitat.** Understorey of lowland evergreen forest, to 900 m, mostly below 600 m. Seemingly requires primary or little-disturbed forest, where it inhabits shaded old treefalls overgrown with vines and small trees.

**Food and Feeding.** Little published. Feeds mainly on insects and other arthropods, up to 10 cm in length, including katydids (Tettigoniidae) and stick-insects (Phasmatidae); stomach contents reported as insects, insect eggs, and a chrysalis. Encountered as pairs or individuals, which forage in dense tangles from ground level up to 4 m above ground, mostly below 2 m. Progresses deliberately by short hops, with pauses to scan. Perch-gleans arthropods from all surfaces of live leaves, vines and branches, and occasionally probes in hanging clusters of dead leaves. Regularly hops on the ground or, especially, along fallen branches near ground;

also perches on small saplings close to ground. Occasionally perches quietly, sitting rather upright and peering around slowly. Sometimes associates with mixed-species flocks passing through its territory, members of which include Lesser Woodcreeper (*Lepidocolaptes fuscus*), White-eyed Foliage-gleaner (*Automolus leucophthalmus*), Black-capped Foliage-gleaner (*Phylidior atricapillus*), *Myrmotherula urosticta* and *M. axillaris*, and Red-crowned Ant-tanager (*Habia rubica*).

**Breeding.** Little known. Season probably Aug-Dec; four specimens with slightly enlarged gonads in Aug, Dec and Jan, one with half-enlarged gonads in Nov, and four with gonads dormant in Jun, Jul and Dec; adult male accompanied by two juvenile males in mid-Oct. One published nest record. 23rd Aug: nest 0.3 m above ground in a shrub 1 m tall in closed forest understorey; 2 eggs, being incubated by female.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Atlantic Forest Lowlands EBA. Historically never common, and its numbers have declined considerably in the past few decades, mainly as a result of loss of primary Atlantic Forest on which it depends. Only a single record from Bahia, in 1928, and the species' presence in the state of Rio de Janeiro has been confirmed at only one locality. Thus, the known range is in essence restricted to Espírito Santo and Minas Gerais, where it occurs at several small reserves: Rio Doce State Park and Fazenda Montes Claros, in Minas Gerais, and Sooretama and Augusto Ruschi Biological Reserve and Linhares Natural Reserve, in Espírito Santo. Main stronghold seems to be Sooretama, where the species was considered fairly common in 1980-1981, and where at least six pairs held territories along 2 km of one forest trail through the 1980s; more recent anecdotal information suggests that it has declined further in the past decade; three territories were located along c. 1.5 km of forest trail in Sooretama in Oct 2000. The species appeared to be less common in nearby Linhares, where surveys of 8-10 km of forest trails detected only two territories. Systematic surveys are needed in order to identify any additional areas not currently protected where the species may exist, and to ascertain current population levels. Additionally, more information is needed on the species' natural history and habitat requirements, which could shed light on its decline and influence possible plans for management. Continued protection of the above-mentioned reserves is critical.

**Bibliography.** Bernardes *et al.* (1990), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Cory & Hellmayr (1924), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Naumburg (1939), Parker (2003a), Ridgely & Tudor (1994), Schulenberg (1983), Scott & Brooke (1985), Sick (1993, 1997), Sick & Teixeira (1979), Sneath (1927), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias *et al.* (1993), Wege & Long (1995), Willis (1984c, 1992b), Zimmer (2003a).

## 57. Bicoloured Antvireo

### *Dysithamnus occidentalis*

**French:** Batará occidental

**German:** Schiefergrauer Würgerling

**Spanish:** Batarito Bicolor

**Other common names:** Western Antvireo/Antshrike, Chapman's Antvireo/Antshrike

**Taxonomy.** *Thamnomphylus aethiops occidentalis* Chapman, 1923, Cocal, 4000 ft [c. 1200 m], Cauca, Colombia.

Relationships of genus not clearly established; preliminary molecular evidence suggests affiliation with *Thamnomphylus*, and morphological characteristics have connected it with *Thamnomanes*. Present species has been variously allocated to both of those genera, but bulk of vocal, morphological and ecological evidence supports its inclusion in current genus. Racial identity of birds on Pacific slope in N Ecuador uncertain; tentatively placed in nominate, but possibly belong to race *punctitectus*. Two subspecies recognized.

#### **Subspecies and Distribution.**

*D. o. occidentalis* (Chapman, 1923) - Pacific Andean slope of S Colombia (Valle, Cauca) and extreme N Ecuador (Carchi).

*D. o. punctitectus* Chapman, 1924 - E Andean slope in Ecuador (Napo, Morona-Santiago).

**Descriptive notes.** 13.5 cm. Male is blackish-grey, paler below; interscapular patch white, greater and median wing-coverts black, dotted white, lesser coverts (exposed only in display) mostly white. Female has upperparts extensively chestnut, wing-coverts spotted buffy white, anterior underparts dark grey with fine white shaft streaks, belly and crissum olive-brown. Subadult male (first basic plumage?) male resembles female, but with larger white wing-covert spots and underpart streaks; an apparent second-year male resembled adult male, but posterior upperparts and underparts brownish and fine white shaft streaks on throat

and breast. Race *punctitectus* is paler (both sexes), with lesser wing-coverts completely white. Voice. Loudsong uncertain, may consist of one of the following calls. Calls include a brief series of notes (usually 3, sometimes 2 or 4) falling in pitch and intensity, repeated at rate of 1 per minute (but variable); short (e.g. 0.25 seconds), variable, downslurred whistle; and a short (less than 1 second) rising series of 3 abrupt notes followed by longer note.

**Habitat.** Understorey of montane evergreen forest; found at 900-2200 m in Colombia and 1500-2200 m in Ecuador. On Mt Sumaco (Napo, Ecuador), race *punctitectus* was found at 1675-1750 m

in primary subtropical forest, but only in natural clearings (treefalls, landslides, light-gaps) where amount of sunlight penetrating the mature forest canopy was greater than average, creating locally dense understorey 2–10 m tall, dominated by woody plants and herbaceous growth with trunks and stems less than 2 cm in diameter at base; forest floor was covered with patchy growth of ferns, small herbaceous plants, and bamboo (in some areas), over thick layer of leaf litter. In Colombia, nominate race was found at Tambito Nature Reserve (Cauca) in a primary-forest treefall clearing, a steep-sloped dense mature secondary palm forest, and ridgetop habitat between 1620 m and 2180 m.

**Food and Feeding.** Little known. Feeds on insects and other arthropods; identified prey items included small caterpillars and a small adult moth (Lepidoptera), a katydid (Tettigoniidae) or mantid (Mantidae) c. 2 cm in length, and a whitish cricket (Gryllidae) c. 4 cm long. In Ecuador, encountered singly or in pairs; birds observed in Jan on Mt Sumaco were not associated with mixed-species flocks. Moved from perch to perch through understorey, stopping to scan for prey for up to 15 seconds (usually less) between movements, while constantly flicking wings and, often, tail. Arthropod prey were perch-gleaned from leaves and twigs, always within 2 m of ground (usually within 1 m); occasionally dropped to ground and flipped fallen leaves to expose prey. Sally-gleaning also commonly employed, usually involving lateral or upward-directed sallies of less than 2 m. Only one instance of dead-leaf searching reported.

**Breeding.** Very little known. One published record of a nest in Ecuador, with both adults attending single nestling, in Dec: an open cup of black fungal filaments and twigs, suspended by rim from fork between two slender green branches, and partly protected by overhanging green leaves.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Chocó EBA and Ecuador-Peru East Andes EBA. Both subspecies only recently rediscovered following decades without being recorded. Species is still known from only a few areas, one of which (the type locality for *punctitectus*) has suffered significant clearance for small-scale agriculture (primarily, planting of naranjilla). The recent Colombian record from headwaters of R Pance is from a site that appears to be just outside Farallones de Cali National Park, and it seems likely that this ornithologically underexplored park may contain a population of this species. Locality data from at least two of the Cauca specimens suggest that the sites may lie within current boundaries of Munchique National Park; this is adjacent to the 3000-ha Tambito Nature Reserve, where recent surveys found nominate race to be uncommon. In Ecuador, Volcán Sumaco is still largely pristine, with an intact forest corridor from lowlands to the highlands; large parts of this ecologically important area are protected, at least on paper, within the Sumaco-Galeras National Park. True conservation of this area would provide a significant reserve for *punctitectus* and many other threatened taxa. Recent range extensions in Ecuador, to Carchi and Morona-Santiago, offer hope that the species may be found in additional locations.

**Bibliography.** Bond & Meyer de Schauensee (1940), Chapman (1924), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Donegan & Dávalos (1999), Fuhrman (2001), Granizo (2002), Greeney (2002), Gyldestolpe (1941a), Hilty & Brown (1986), Isler & Whitney (2002), Krabbe & Palacio (1999), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg (1983), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whitney (1992a), Zimmer (1933a).

## Genus *THAMNOMANES* Cabanis, 1847

### 58. Dusky-throated Antshrike

#### *Thamnomanes ardesiacus*

**French:** Batará ardoisé

**Spanish:** Batará Gorgioscuro

**German:** Nördlicher Schwarzkehlwürgerling

**Other common names:** Grey-throated Antshrike/Antvireo

**Taxonomy.** *Dysithamnus ardesiacus* P. L. Selater and Salvin, 1868, Rio Napo, Ecuador. Relationships to other genera unclear. Species currently placed in genus appear to be related on basis of morphology and behaviour, although their nest architecture is somewhat variable. Present species has sometimes been placed in genus *Dysithamnus*. Forms a superspecies with *T. saturninus* and has been treated as conspecific; taxonomic study of populations needed. Races appear to intergrade; specimens in N part of range of nominate approach *obidensis* in extent of black on male throat, and region in E Colombia that is said to separate races is poorly known ornithologically; further work required. Two subspecies recognized.

#### **Subspecies and Distribution.**

*T. a. ardesiacus* (P. L. Selater & Salvin, 1868) - SC & SE Colombia (near base of Andes S from Meta and C Caquetá, also extreme SE Amazonas) S to E Peru (except SE Loreto S of Amazon and E of R Ucayali), NE Bolivia (Pando, NW La Paz) and adjacent Brazil (SE Acre).

*T. a. obidensis* (Snethlage, 1914) - E & S Venezuela (Delta Amacuro, Bolívar, Amazonas), the Guianas, E Colombia (Guainía, E Vaupés) and N Amazonian Brazil (R Negro drainage to N Pará and Amapá).

**Descriptive notes.** 13–14 cm; 16–19 g. Male nominate race is darkish grey, paler on belly, small white interscapular patch (sometimes absent), tail slightly tipped white; often some black feathers on throat in N of range. Distinguished from *T. saturninus* by shorter bill (only slight overlap in measurements), lesser amounts of black on throat, white interscapular patch smaller or absent. Female is dark olive-brown above, wings and tail more rufous, throat buff-white, pale buffy ochraceous below. Subadult male initially resembles female but more cinnamon-brown, later like male except centre of throat feathers white, cinnamon-

brown feathers retained especially on wing-coverts and lower underparts; subadult female more oliveaceous than adult female, especially across breast. Race *obidensis* has shorter tail, male throat black, wings sometimes with some white. **VOICE.** Loudsong a moderately long series of notes (e.g. 12 notes, 3 seconds) that gradually become shorter, more intense, and rise in pitch before dropping into final raspy note (final note may be omitted, or may be repeated 2–3 times). Calls include short (e.g. 0.5–1 second) “chirr”, downslurred raspy note, and more abrupt, clearer note.

**Habitat.** Understorey of lowland evergreen forest, to 1050 m. Primarily in *terra firme* forest; less common in seasonally flooded forest.

**Food and Feeding.** Feeds mostly on various insects, also other arthropods. In study of stomach contents of nine specimens from S Peru, four-fifths of all insect remains were either katydids (Tettigoniidae), other orthopterans and cockroaches (Blattidae), or beetles (Coleoptera); remainder included true bugs (Hemiptera), wasps (Hymenoptera), adult and larval lepidopterans, also other arthropods (e.g. spiders); a small unidentifiable lizard found in one stomach. Forages in pairs, individually, or in family groups, 0–10 m above ground, mostly 0–4 m, perching somewhat upright on horizontal fronds of small understorey palms and on branches of slender saplings, where pauses for 2–30 seconds while turning the head slowly as it scans for prey; perches less upright than, and seldom pauses as long as, *T. caesi* and *T. schistogynus*. Sallies diagonally or vertically to take prey primarily from underside of foliage (less frequently from tops of leaves, stems, the air, tree trunks, or ground) up to 2.5 m away, typically continuing flight on to another perch following capture; sometimes perch-gleans prey from nearby substrates, including dead leaves. Usually closely associated with mixed-species understorey flocks, particularly those with *T. caesi* or *T. schistogynus*, foliage-gleaners (of genus *Automolus*), *Myrmotherula longipennis* and other antwrens (*M. gutturalis*, *M. leucophthalma*, *M. haematotota* or *M. fieldsaai*, the exact one depending on geographical location), Tawny-crowned Greenlet (*Hylophilus ochraceiceps*) and Red-crowned Ant-tanager (*Habia rubica*); in many areas seems to show particular preference for following *M. longipennis*, often perching within 2–3 m of latter and following it each time it moves to another tree. Regularly (but not habitually) attends army ants (*Eciton burchei*), leaving mixed-species flocks to follow swarm for up to 2–3 hours; usually stays in open understorey, avoiding dense ground cover used by obligate ant-followers; also seen foraging over smaller, unidentified ants; observed with woodcreepers (Dendrocolaptidae) sallying after winged ants fleeing from nests as army ants approached.

**Breeding.** Nests and/or young in Jun–Oct in French Guiana; fledgling in Oct in Brazil (Manaus). In French Guiana, cup-nest of fungal (*Marasmius*) filaments, the exterior garnished with dried leaves with disarrayed appearance (simulating pile of leaves caught in branches), 1–6 m up in fork of horizontal branch of small tree in undergrowth on a hill, another nest 1–9 m off ground; 2 eggs, pinkish-white with large violaceous patches, incubation period 11–12 days. Seven nests in Peru described as like that of a vireo (*Vireo*), often festooned with leaves, 0.5–2 m up in fork of sapling.

**Movements.** None recorded; presumed resident throughout its range.

**Status and Conservation.** Not globally threatened. Considered fairly common throughout its large range. Range includes numerous parks and reserves: examples are Canaima, Duida and Yacapana National Parks, in Venezuela, Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam, Jaú, Pico da Neblina and Monte Roraima National Parks, in Brazil, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Madidi National Park, in Bolivia. These protect vast areas of suitable habitat. In Venezuelan study, this species survived selective logging in a forest, but population density was reduced, substantially so after some types of logging.

**Bibliography.** Álvarez (1994), Alverson, Moskovits & Shopland (2000), Alverson, Rodríguez & Moskovits (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Dick *et al.* (1984), Foster *et al.* (1994), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Mason (1996), Meyer de Schauensee & Phelps (1978), Munn (1984, 1985), Munn & Terborgh (1979), Novaes (1980), O’Neill (1974), Oniki & Willis (1972, 1982), Parker (2003a), Parker & Bailey (1991), Parker & Remsen (1987), Pearson (1975c), Remsen (1986), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg (2003), Schulenberg (1983), Servat (1996), Sick (1993), Snyder (1966), Stotz (1990b, 1993), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Terborgh & Weske (1969), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1988a, 1994), Tostain (2003), Tostain *et al.* (1992), Wiley (1980), Willis (1977, 1984e), Zimmer, J.T. (1932e), Zimmer, K.J. (2003a).

### 59. Saturnine Antshrike

#### *Thamnomanes saturninus*

**French:** Batará saturnin

**German:** Südlicher Schwarzkehlwürgerling

**Spanish:** Batará Saturnino

**Taxonomy.** *Thamnophilus saturninus* Pelzel, 1868, Borba, Rio Madeira, Brazil.

Relationships to other genera unclear. Species currently placed in genus appear to be related on basis of morphology and behaviour, although their nest architecture is somewhat variable. Present species has sometimes been placed in genus *Dysithamnus*. Forms a superspecies with *T. ardesiacus* and has been treated as conspecific; taxonomic study of populations needed. Extent of geographical ranges of races unclear; *huallagae* may not be distinguishable from nominate. Two subspecies recognized.

#### **Subspecies and Distribution.**

*T. s. huallagae* (Cory, 1916) - NE Peru S of R Amazon (along S bank of R Marañón to R Huallaga, and S to R Ucayali in S Loreto) and SW Amazonian Brazil (drainage of upper R Jurúá, S to W Acre).

*T. s. saturninus* (Pelzel, 1868) - SC Amazonian Brazil (from lower R Jurúá and upper R Purus E to S bank of R Tapajós and both banks of R Teles Pires) S to Rondônia, N Mato Grosso and extreme NE Bolivia (NE Santa Cruz).

**Descriptive notes.** 13.5–14.5 cm; 19–21 g. Male is darkish grey, with black throat and upper breast; white interscapular patch, white tips of wing-coverts, white edges at bend of wing, tail thinly tipped white, belly feathers spottily edged white (sometimes absent). Distinguished from *T. ardesiacus* by more extensive black throat, larger interscapular patch, longer bill (only slight overlap in measurements). Female is rufescent-tinged olive-brown above, wings and tail rufous, white throat contrasting with olive breast, deep tawny-buff below. Race *huallagae* has less black on throat, female differs from nominate in having throat feathers

spotted grey, breast darker. **VOICE.** Loudsong a moderately long series of notes, gradually becoming shorter and rising in pitch, before lower-pitched final rasping note. Calls include short “chirr”, downslurred rasp, and abrupt, clearer note. Vocalizations similar to those of *T. ardesiacus*; detailed analysis of possible differences currently unavailable.

**Habitat.** Understorey of lowland evergreen forest, mostly below 300 m; to 650 m in NE Bolivia. Primarily in *terra firme* forest; less common in seasonally flooded forest.

**Food and Feeding.** Feeds on variety of insects, including katydids (Tettigoniidae), mantids (Mantidae), adult and larval lepidopterans, true bugs (Hemiptera), and probably other arthropods. Forages in pairs, singly, or in family groups, mostly 1–4 m above ground, perching semi-upright on slender branches or horizontal fronds of small understorey palms, where it pauses for 2–30 seconds, actively scanning; perches more horizontally than *T. caesi* and *T. schistogynus*, and seldom pauses as long as those species. From perch, sallies diagonally and vertically to take prey from air or from foliage and stems (less frequently from trunks or ground) up to 2.5 m away, typically continuing on to an-

other perch following capture. Usually closely associated with mixed-species understorey flocks of other insectivores, particularly Elegant Woodcreeper (*Xiphorhynchus elegans*), *Myrmotherula longipennis*, *M. leucophthalma*, Tawny-crowned Greenlet (*Hylophilus ochraceiceps*) and Red-crowned Ant-tanager (*Habia rubica*); often in same flocks with *T. caesi*us, but generally forages lower than that species (some overlap). Sometimes follows raiding swarms of army ants (*Eciton burckhelli*).

**Breeding.** Nothing published. One report of female flushed from a nest in Aug in NE Peru; nest a small cup suspended from two horizontal limbs 3 m above ground in small sapling.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common throughout its range, much of which remains little developed and relatively inaccessible. Range includes some large protected areas, e.g. Tapajós and Pacaás Novos National Parks, in Brazil, and Noel Kempff Mercado National Park, in Bolivia. At one site, numbers were reduced substantially after selective logging.

**Bibliography.** Cory & Hellmayr (1924), Isler & Whitney (2002), Johns (1991), Killen & Schulenberg (1998), Oren & Parker (1997), Parker (2003a), Ridgely & Tudor (1994), Robbins (2003b), Schulenberg (1983), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Willis (1984c), Zimmer, J.T. (1932e), Zimmer, K.J. (2003a).

## 60. Cinereous Antshrike

### *Thamnomanes caesi*us

**French:** Batara cendré

**German:** Einfarbwürgerling

**Spanish:** Batará Cinéreo

**Taxonomy.** *Muscicap*a *caesia* Temminck, 1820, Bahia, Brazil.

Relationships to other genera unclear. Species currently placed in genus appear to be related on basis of morphology and behaviour, although their nest architecture is somewhat variable. Forms a superspecies with *T. schistogynus* and formerly treated as conspecific. Five subspecies recognized.

**Subspecies and Distribution.**

*T. c. glaucus* Cabanis, 1847 - S Venezuela (Bolívar, Amazonas), the Guianas, E Colombia (S from Meta and Vichada), N Brazil (N Amazonas E to Amapá), E Ecuador and NE Peru (N of R Amazon and W of R Ucayali, S to N Ucayali).

*T. c. persimilis* Hellmayr, 1907 - C Brazil S of R Amazon (lower R Jurua and lower R Purus E to left bank of R Tapajós, S to N Rondônia and W Mato Grosso) and extreme NE Bolivia (NE Santa Cruz).

*T. c. similis* Gyldenstolpe, 1951 - SC Amazonian Brazil: known only from middle R Purus.

*T. c. hoffmanni* Hellmayr, 1906 - EC Brazil S of R Amazon (from right bank of R Tapajós E to W Maranhão, S to NE Mato Grosso).

*T. c. caesi*us (Temminck, 1820) - coastal E Brazil (Pernambuco S to Rio de Janeiro, and inland in R Doce drainage in Minas Gerais).

**Descriptive notes.** 14.5 cm; 16–18 g. Male nominate race is rather dark grey, underwing-coverts and inner edges of secondaries white. Female has upperparts and side of head dark olive-brown, small white interscapular patch (lacking on male), wings and tail tinged rufous, throat buff, breast, sides and flanks olive, tinged tawny-cinnamon, centre of belly and crissum tawny-cinnamon. Race *hoffmanni* male is paler than nominate, auriculars and throat feathers with white shaft streaks (sometimes widening into spots on throat), female throat is paler, buff-white with dusky feather bases, flanks less olive, clearer tawny-cinnamon; *persimilis* male is

slightly darker than last and lacks white streaks on auriculars and throat, female tinged cinnamon-rufous throughout, lower breast and rear underparts cinnamon-rufous; *similis* is darker than nominate and has small white interscapular patch, female similar to previous; *glaucus* male has whitish throat, female is tinged rufous throughout with lower breast and rear underparts deep tawny-rufous, both sexes with large white interscapular patch. **VOICE.** Loudsong a moderately long (e.g. 5 seconds) series in which long clear upslurred notes shorten and diminish in pitch, gradually becoming a rattle, initial note shorter, flatter and lower-pitched than second note. Calls include short rattle, typically introduced by distinct clearer note; 2 upslurred notes given in quick succession; and shorter upslurred note, sometimes repeated regularly (e.g. every 0.5 seconds).

**Habitat.** Understorey and mid-storey of lowland evergreen forest, mostly below 600 m; to 900 m in Andes, to 1100 m in tepuis of Venezuela. Occupies both *terra firme* and seasonally flooded (*várzea* and *igapó*) forests; rarely found in second growth.

**Food and Feeding.** Feeds on various insects, including hemipterans, homopterans (Jassidae), beetles (Coleoptera: Chrysomelidae) and ants (Formicidae: Ponerinae), and other arthropods. A sentinel of mixed-species flocks, maintaining flock cohesiveness with its constant noisy vocalizations, sounding alarm when predators appear, and capturing arthropods flushed by nearby perch-gleaning species in flock. Forages in pairs, individually, or in family groups. Perches in upright, vertical posture 1.5–2.0 m above ground on open branches (usually horizontal or inclined) or looping vines, for several seconds to up to 2 minutes at a time, always peering about rapidly. Makes quick, darting sallies of up to 10 m (more often 1–5 m) to take from air prey escaping from other species, or picks items from foliage, stems and vines (less commonly from trunks, rarely from ground), typically continuing flight on to another perch to consume prey; also makes shorter, looping sallies, usually to air, returning to original (or nearby) perch. Tends to take relatively large items, often spending considerable time bashing these on limbs and mandibulating them before swallowing. Often in same flocks as either *T. ardesiacus* or *T. saturninus*, then typically foraging higher above ground than either congener (but some overlap). In areas where no sympatric congeners, and in certain lower-strata habitats (e.g. stands of *Guadua* bamboo), commonly forages as low as 1–5 m above ground and often with understorey flocks that include large numbers of *Myrmotherula* antwrens; in areas of range overlap with other *Thamnomanes*, more often in mid-storey (5–20 m), sometimes associating with woodcreepers (Dendrocolaptidae), foliage-gleaners (Fumariidae), greenlets (*Hylophilus*) and tanagers (Thraupidae). Occasionally follows army ants (*Eciton burckhelli*, *Labidus praedator*), usually for short periods coincident with movement of a mixed-species flock past a swarm, but in absence of either *T. saturninus* or *T. ardesiacus* may follow ants for up to 4 hours; only in open areas of understorey, never in dense micro-habitats; perch heights over ants mostly 1–7 m, occasionally as low as 0–3 m, sallying short distances to air, foliage, stems, trunks, branches and even ground to capture flushed prey.

**Breeding.** Jul–Dec in Brazil and Aug–Dec (once May) in French Guiana. Nest a deep, leafy cup, external diameter 15 cm, depth 5 cm, constructed of dried, rotten leaves, rhizomorphs and fine rootlets, lined with finer plant fibres, fungal (*Marasmius*) fibres and/or dried leaves (overall aspect of a pile of leaves or debris), placed 1–3.5 m up in low sapling or bush, into dead-leaf accumulation in a climber (Cyclanthaceae) on small tree, or on dead leaves accumulated on large leaves of a palm (*Astrocaryum murumuri*); a nest in Brazil (near Belém) was 1–4 m above ground on same species of palm, another 1–8 m up on a vertical support formed by bases of several leaves of the maranthaceous plant guaraná

(*Schinosoph* *ovatus*); some materials identified from one of these nests were leaves of *Tetragastris* (Bursaceae), *Coupia* (Rosaceae) and *Hevea* (Euphorbiaceae) and pieces of pteridophytes (Pteridophyta); a nest in Venezuela was constructed mostly of dead leaves, fibrous plant material and spider webs, 1–8 m above ground on side of slender, spiny-trunked understorey palm, at juncture with a lateral branch. Normal clutch 2 eggs, pinkish-white, blotched and streaked reddish-brown.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Considered fairly common to common throughout most of its large range. This includes numerous parks and reserves, such as the following: Canaima, Duida and Yacacana National Parks, in Venezuela; Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam; Jaú, Pico da Neblina, Tapajós and Monte Roraima National Parks, in Brazil; Yasuni National Park, in Ecuador; Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru; Noel Kempff Mercado National Park, in Bolivia. These protect vast areas of suitable habitat. Nominally race in coastal Brazil is an exception: suitable forest habitats throughout its range have been greatly reduced by deforestation, and preservation of existing parks and forest reserves is vital to maintain population levels of this taxon.

**Bibliography.** Alvarez (1994), Alverson *et al.* (2001), Beebe *et al.* (1917), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Dick *et al.* (1984), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Killen & Schulenberg (1998), Mason (1996), Meyer de Schauensee & Phelps (1978), Munn (1984, 2003), Munn & Terborgh (1979), Novaes (1969, 1970, 1980), Oniki (1971b, 1972a), Oniki & Willis (1972, 1982, 1983b), Oren & Parker (1997), Pearson (1975c), Pinto (1953), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schubert *et al.* (1965), Schulenberg (1983), Scott & Brooke (1985), Sick (1993, 1997), Snyder (1966), Stotz (1990b, 1993), Stotz & Bierregaard (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Thiollay (1988a, 1994), Tostain (2003), Tostain *et al.* (1992), Wiley (1980), Willis (1977, 1984e), Zimmer, J.T. (1932e), Zimmer, K.J. (2003a).

## 61. Bluish-slate Antshrike

### *Thamnomanes schistogynus*

**French:** Batara bleu-gris

**German:** Blaugrauer Würgerling

**Spanish:** Batará Azulino

**Taxonomy.** *Thamnomanes caesi*us *schistogynus* Hellmayr, 1911, Cochabamba, Bolivia.

Relationships to other genera unclear. Species currently placed in genus appear to be related on basis of morphology and behaviour, although their nest architecture is somewhat variable. Forms a superspecies with *T. caesi*us and sometimes considered conspecific. Races probably reflect a cline in darkness of plumage, but further study required. Two subspecies recognized.

**Subspecies and Distribution.**

*T. s. intermedius* Carrker, 1935 - C Peru S of R Amazon and E of R Huallaga (S to Junín).

*T. s. schistogynus* Hellmayr, 1911 - W Brazil S of R Amazon (W of lower R Jurua and S to its middle and upper reaches and to upper R Purus), SE Peru (S from Junín) and NW Bolivia (W Pando, La Paz, Cochabamba).

**Descriptive notes.** 13.5–14.5 cm; 16–18 g. Male is darkish grey throughout, except for concealed white interscapular patch; tail sometimes with minute white tips. Female is slightly browner and paler, with belly and flanks deep cinnamon-rufous, auriculars and throat feathers with white shaft streaks. Race *intermedius* is darker. **VOICE.** Loudsong a moderately long series of long upslurred notes that shorten and drop in pitch, gradually becoming a rattle, first note shorter and lower than second; similar in form to that of *T. caesi*us. Calls include a rattle, usually introduced by distinct note sounding like a whine; similar notes given in

succession but varying in form; also a downslurred note, and a soft chatter of variable abrupt notes. **Habitat.** Understorey and mid-storey of lowland evergreen forest, to 1200 m, mostly below 800 m. Occupies both *terra firme* and *várzea* forests, often particularly in light-gaps with abundant bamboo and vine tangles.

**Food and Feeding.** Feeds on insects, including beetles (Coleoptera), katydids (Tettigoniidae), grasshoppers (Acrididae), ants (Hymenoptera), true bugs (Hemiptera), adult and larval lepidopterans, mantids (Mantidae), and other arthropods, including spiders; also small lizards and snails. A sentinel of mixed-species flocks, maintaining flock cohesiveness with its constant noisy vocalizations, sounding alarm when predators appear, and capturing arthropods flushed by nearby perch-gleaning species. Forages in pairs, singly, or in family groups, 1.5–13 m (mostly 3–8 m) above ground, perching in upright, vertical posture on open branches (usually horizontal or inclined), looping vines or angled stems of bamboo; perches for several seconds to up to 2 minutes at a time, peering about rapidly and actively scanning, then making quick darting sallies of 1–5 m to seize in air prey escaping from other species, or hover-gleaning prey from foliage, stems and vines (less commonly from trunks, rarely from ground); typically continues flight on to another perch to consume prey. Also makes shorter, looping sallies, usually to the air, but also repeatedly to foliage to exploit insect infestations or clusters of caterpillars, returning to original (or nearby) perch after each sally. Tends to take relatively large items, often spending considerable time bashing these on limbs and mandibulating them before swallowing. Often in same flocks as either *T. ardesiacus* or *T. saturninus*, depending on location, and usually foraging slightly higher than those, although some overlap.

**Breeding.** Jun–Nov in Peru. Nest a deep, leafy cup of dried, rotten leaves, straw-like material and fine rootlets, lined with finer plant fibres (overall aspect of a pile of leaves or debris); one was placed over a cluster of dead leaves with live vines growing through it 3 m off ground on forked branch of a fallen tree; another was 1 m up at base of a pinnate branch of a tree fern; another was 1 m up in fork of sapling 2–5 cm thick where two small leafy branches diverged from trunk; a fourth was 8 m up along an inclined palm frond where dead *Crotopia* leaves had lodged. Normal clutch 2 eggs, white with reddish or brownish blotches over entire surface; sexes recorded as sharing in feeding of nestlings.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout its range, much of which remains little developed and relatively inaccessible. Range includes some large protected areas, e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru. Serra do Divisor National Park, in Brazil, and Madidi National Park, in Bolivia.

**Bibliography.** Alverson, Moskovits & Shopland (2000), Alverson, Rodriguez & Moskovits (2001), Cory & Hellmayr (1924), Foster *et al.* (1994), Hilty (2003b), Isler, M.L. & Isler (2003a, 2003b), Isler, P.R. & Whitney (2002), Munn (1984, 1985), Munn & Terborgh (1979), Novaes (1957b), O'Neill (1974), Parker (2003a), Parker & Bailey (1991), Parker & Remsen (1987), Parker *et al.* (1982), Remsen (1986), Ridgely & Tudor (1994), Robbins (2003b), Robinson & Terborgh (1997), Rosenberg (2003), Schulenberg (1983), Servat (1966), Sick (1993), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Zimmer, J.T. (1932e), Zimmer, K.J. (2003a).

PLATE 50

inches 3  
 cm 8

# Genus MYRMOTHERULA P. L. Sclater, 1858

## 62. Pygmy Antwren

### Myrmotherula brachyura

**French:** Myrmidon pygmée

**German:** Östlicher Weißkehl-Ameisenschlüpfer

**Spanish:** Hormiguerito Pigmeo

**Taxonomy.** *Muscicapae* *brachyurae* Hermann, 1783, Cayenne.

Genetic and morphological analyses indicate that this species and *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* represent a monophyletic group (the "streaked antwren assemblage"). Present species is closely related to first of those, which was treated as a race of it by earlier authors, but recently shown to differ vocally and in plumage. Studies needed in order to determine whether any diagnosable differences exist among the various populations. Monotypic.

**Distribution.** C & E Colombia (base of Andes S from Meta, and extreme E in Guianá, Vaupés and Amazonas), E Ecuador, E Peru, S Venezuela (Bolívar, Amazonas), the Guianas, Amazonian Brazil (E to R Tocantins, S to N & W Mato Grosso) and NW & NE Bolivia.

**Descriptive notes.** 7.5-8 cm; 6-8 g. Small size, tiny tail. Male has crown and upperparts black, streaked white, streaks faintly tinged yellow except on crown; black postocular stripe, white cheeks; rump grey, unstreaked; white interscapular patch; wings black, median and greater coverts tipped white, flight-feathers edged white; throat white, narrow dark malar streak; underparts yellow, sides sparsely streaked black. Female is like male except for buff tinge on pale areas of head, mantle and breast side, no interscapular patch; throat and breast pale buff in N populations. **Voice.** Loudsong an accelerating, uncountable series of short notes (e.g. 20

notes, 2-3 seconds) that become more abrupt while increasing and then decreasing in pitch and intensity. Calls appear to vary regionally, include short whistles repeated irregularly, a short, rapid musical trill (variable, often slowing and falling in pitch), and abrupt chip, sometimes strung into a rattle.

**Habitat.** Canopy and subcanopy of lowland evergreen forest (including *terra firme*, *várzea* and transitional forest), foothill evergreen forest, and second-growth woodland, to 900 m, mostly below 600 m. Tends to favour edges, including margins of light-gaps (such as treefalls) within intact forest. Primarily in vine tangles and portions of the canopy having dense, multiple overlapping leaf layers; particularly in lower canopy or upper mid-storey. Much more of an edge bird than sympatric *M. sclateri*.

**Food and Feeding.** Feeds on variety of small insects; probably also spiders. Stomach contents of specimens from Brazil and Surinam included lepidopterans, orthopterans (Acrididae), hemipterans, homopterans (Membracidae), coleopterans, hymenopterans (Formicidae). Closely associated partners, individuals, or family groups forage mostly from 8 m to 25 m or more above ground, occasionally lower; in studies at three locations in Peru and Brazil, mean foraging heights were 12.5 m, 10.6 m and 11.8 m. Forages alone or accompanies mixed-species flocks that move through its small territory, dropping out as flock moves on. Often in same flocks as *M. sclateri*, then foraging at lower heights, on average, than that species, but the two occasionally work the same dense vine tangles in interior canopy. Progresses rapidly through vegetation by short hops, seldom pausing for more than 1-2 seconds between movements. Perch-gleans prey from all surfaces of live leaves (mostly), vines and branches, using reaches or quick lunging stabs; also frequently makes short, upward-directed, fluttering sallies to glean prey from undersides of overhanging leaves. Often flicks wings while foraging.

**Breeding.** Little known. In Brazil, female with egg in oviduct in Jun in Acre, and pair feeding fledglings in Jan near Manaus; in Colombia (near Leticia), individual seen building bulky nest c. 6 m above ground in *várzea* on 29 Aug; in N Peru (N of R Amazon), pair carrying whitish strands of grass-like nesting material in Jun.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Considered to be fairly common throughout its extensive range. This includes numerous large parks and reserves in most countries in which it occurs, examples of which are: Caura Forest Reserve and Imataca Forest Reserve and El Dorado, Alto Orinoco-Casiquiare Biosphere Reserve, and Yacacana, Duida and La Neblina National Parks, in Venezuela; Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam; Amacayacu National Park, in Colombia; Serra do Divisor, Jaú and Tapajós National Parks and Cristalino State Park, in Brazil; Yasuni National Park, in Ecuador; Manu National Park and Biosphere Reserve, Tambopata-Candamo Reserved Zone and Pacaya-Samiria National Reserve, in Peru; and Madidi and Noel Kempff Mercado National Parks, in Bolivia. The species' range also contains extensive, intact habitat which, although not formally protected, appears to be at little short-term risk of development.

**Bibliography.** Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003c), Isler, M.L. *et al.* (1998), Isler, P.R. & Whitney (2002), Meyer de Schauensee & Phelps (1978), Munn & Terborgh (1979), Novaes (1957b), O'Neill & Pearson (1974), Oniki & Willis (1982), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Pearson (1977a), Remsen *et al.* (1986), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Servat (1996), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tallman & Tallman (1994), Terborgh *et al.* (1990), Thiollay (1994), Whitney (2003a), Zimmer, J.T. (1932a), Zimmer, K.J. (2003a), Zimmer, K.J. & Hilty (1997), Zimmer, K.J., Parker *et al.* (1997).

## 63. Moustached Antwren

### Myrmotherula ignota

**French:** Myrmidon de Griscom

**German:** Westlicher Weißkehl-Ameisenschlüpfer

**Spanish:** Hormiguerito de Griscom

**Other common names:** Griscom's/Colombian Antwren; Short-billed Antwren (*obscura*)

**Taxonomy.** *Myrmotherula brachyura ignota* Griscom, 1929, Jesuito, Darién, Panama.

Genetic and morphological analyses indicate that this species and *M. brachyura*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* represent a monophyletic group (the "streaked antwren assemblage"). Present species is closely related to first of those, and nominate race formerly considered conspecific, but differs in vocalizations and plumage. Race *obscura* often treated as a separate species, but vocally indistinguishable from nominate. Two subspecies recognized.

**Subspecies and Distribution.**

*M. i. ignota* Griscom, 1929 - E Panama (Caribbean slope in Canal area and San Blas, Pacific slope in E Panamá and Darién), W & N Colombia (Pacific slope and along N base of Andes E to Santander) and NW Ecuador (Esmeraldas, SW Imbabura, NW Pichincha).

*M. i. obscura* J. T. Zimmer, 1932 - SC & E Colombia (locally along base of Andes S from Meta, and in Guianá and Vaupés), E Ecuador, NE Peru (S to Pasco and Ucayali), and SW & WC Amazonian Brazil (extreme SW S to NW Acre, and EC Amazonas along R Solimões).

**Descriptive notes.** 7.5-8 cm. Small size, tiny tail. Male is black above, narrowly streaked white, faintly tinged yellow except on crown, broad black postocular streak, white cheeks; white interscapular patch; wing-coverts tipped white, flight-feathers edged white; throat white, broad dark malar streak; underparts yellow, sides sparsely streaked black. Distinguished from similar *M. brachyura* mainly by broader malar streak, more prominent post-ocular streak, more extensive black on upperparts. Female is like male except light streaks on crown and side of head buff to tawny-buff, no interscapular patch. Race

*obscura* male differs from nominate in having fewer pale streaks above, female head, throat and breast more buffy. **Voice.** Loudsong an accelerating series of short notes increasing and then decreasing in pitch and intensity, similar in pattern to that of *M. brachyura* but pace slower and notes, although still uncountable, are more musical, less abrupt. Call a short, uneven, downslurred whistle; *obscura* also an abrupt note (not yet recorded for nominate race).

**Habitat.** Canopy and subcanopy of lowland evergreen forest, nominate race also in taller second-growth woodland; mainly below 600 m, but locally to 1100 m in Panama and to 900 m in W & N Colombia (nominate). Found primarily at forest borders with tall trees, or at margins of light-gaps (large treefalls) and stream edges within continuous forest. Race *obscura* occurs in both *terra firme* and *várzea*; more commonly found in canopy of continuous forest than is frequently syntopic *M. brachyura*.

**Food and Feeding.** Little published; most information pertains to race *obscura*. Feeds on variety of small insects, particularly lepidopteran larvae; probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly 10-40 m above ground, in denser foliage and vine tangles from canopy down to lower mid-storey and crowns of saplings; stays higher in unbroken forest, descending lower along borders, stream edges, clearings, and wherever there are breaks in the canopy. Forages alone or with mixed-species flocks of insectivores. Very active, hitching from side to side as it zigzags through vines and slender branches, scanning foliage as it goes, seldom pausing for more than 1-2 seconds between hops, constantly flicking wings. Perch-gleans prey from leaf, stem, moss, twig and vine surfaces by reaching or by quick lunging stabs; often makes short fluttering sallies, mostly upwards to underside of overhanging vegetation, and occasionally hover-gleans. Race *obscura* sometimes in same mixed flocks as *M. brachyura*; ecological distinctions between the two taxa not well understood, but *obscura* may follow flocks more faithfully and for longer distances, particularly in unbroken canopy.

**Breeding.** Previously unpublished observation of nest-building by pair in Aug in N Peru (*obscura*): nest a small bag c. 6 cm wide and 6 cm deep, constructed entirely of jagged bright green lichen and spider webs, suspended c. 9 m off ground in fork of slender twigs c. 0.5 cm thick on leafy branch near crown centre of tree 12 m tall, surrounded by taller (25 m) trees, in *terra firme* forest.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Generally considered uncommon to fairly common throughout its range, which includes a number of formally protected parks and reserves. Among these are Soberanía and Darién National Parks, the Atlantic-coast forest (Colón) and Comarca Kuna Yala Indigenous Reserve (San Blas), in Panama, and Los Katios National Park, in Colombia; and, for race *obscura*, Yasuni National Park, Limoncocha Biological Reserve and Cuyabeno Reserve, in Ecuador, and Pacaya-Samiria National Reserve, in Peru. This inconspicuous, subcanopy-dwelling antbird is easily overlooked. Nominative race, in particular, is probably more widespread within its range than current scatter of records would indicate; this already proven to be the case in NW Ecuador, where number of records and known sites has increased markedly since the species was first discovered there, in 1995. Much of this species' range has been little affected by human disturbance to date, although intensified oil exploration and concomitant road-building and human colonization in much of E Ecuador, along with completion of the Pan-American highway in Panama-Colombia, pose potential future threats.

(1932a), Zimmer, K.J. (2003a).

## 64. Guianan Streaked Antwren

### Myrmotherula surinamensis

**French:** Myrmidon du Surinam

**German:** Guayana-Strichelameisenschlüpfer

**Spanish:** Hormiguerito de Surinam

**Taxonomy.** *Sitta surinamensis* J. F. Gmelin, 1788, Surinam.

Considered a sister-species of *M. multistriata*; until recently was treated as conspecific with that and also with *M. pacifica*, but vocal and plumage characters indicate that they are all separate species. Genetic and morphological analyses indicate that all three species are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. cherriei*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** S Venezuela (S Delta Amacuro, Bolívar, Amazonas), the Guianas and N Brazil (E Roraima E to Amapá).

**Descriptive notes.** 9-10 cm; 7.5-9 g. Male has crown and upperparts black, streaked white; wing-coverts tipped white, flight-feathers edged white; white interscapular patch broad (nearly entire width between scapulars); tail black, edged white, tips spotted white; thin malar streak black, throat and anterior underparts white, flanks and crissum grey, black streaks extending from throat to belly and flanks. Female differs from male in having top of head cinnamon-rufous, crown and nape streaked black, side of head, breast and sides orange-buff, head side faintly streaked, no malar streak, lower underparts faintly tinged

buff, underparts unstreaked or with band of fine streaks across breast and sides. **Voice.** Loudsong a rattle or trill of unmusical notes, initially rises in intensity and pitch and then decelerates slightly. Stereotyped call a distinctive, song-like but rapidly delivered series of short notes (e.g. 8 notes, 1-2 seconds) that rises and falls in pitch. Calls include slightly downslurred, complaining note, often given in doublet with second note shorter and lower; also short rattle, and single, abrupt "chit".

**Habitat.** Understorey and mid-storey of lowland evergreen-forest edge and shrubby second growth, to 450 m. Almost entirely a water-edge species, inhabiting shrubby thickets and vine tangles overlooking banks of rivers, streams and ponds; also in mature mangroves where rivers empty into sea in French Guiana. Occasionally found in shrubby borders of forest or large forest clearings away from water.

**Food and Feeding.** Little published. Feeds mostly on small insects, particularly small lepidopteran larvae, and spiders; stomach contents of Surinam specimens included spiders, hemipterans, homopterans (Jassidae), also berries. Forages in pairs or individually in leafy shrubs, crowns of saplings, vine tangles surrounding trunks of larger trees, and dead branches of fallen or partially submerged trees, mostly 1-15 m above ground or water. Very active, hitching from side to side as it zigzags through vegetation, often changing direction and retracing route, scanning as it goes, seldom pausing for more than 1-2 seconds between movements. Prey gleaned from tops and bottoms of live leaves, stems, vines and branches, by reaches and quick lunging stabs, as well as by short, upward-directed, fluttering sallies to underside of overhanging vegetation. May briefly join passing mixed-species flocks.

**Breeding.** Little known. Four nests in French Guiana in Aug-Oct (previously unpublished data); pair of adults with two fledglings just out of nest in late Feb in Surinam; adults with closely associated juveniles recorded in early Feb in Brazil (Amapá). In French Guiana, nest covered externally with green moss, placed on branch 0.5-1 m above water; 2 eggs, whitish, ring of violaceous-brown splotches on blunt end. Other eggs described as creamy yellow with purplish-brown and purplish-grey spots, but description requires confirmation.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout most of its range, which includes extensive areas of intact habitat and some large, protected areas, e.g. Yapacana, Duida and La Neblina National Parks and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela. Although relatively few of the areas occupied by this species are formally protected, the bulk of its range has suffered little from development and human colonization. The ability of this species to persist in shrubby second-growth habitats makes it less sensitive to disturbance than many other forest species.

**Bibliography.** Cory & Hellmayr (1924), Gyldenstolpe (1930b), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Isler, M.L. *et al.* (1998, 1999), Isler, P.R. & Whitney (2002), Meyer de Schauensee & Phelps (1978), Oniki (1971b), Ridgely & Tudor (1994), Ridgway (1911), Schönwetter & Meise (1967), Sick (1993), Snyder (1966), Stotz *et al.* (1996), Tallman & Tallman (1994), Tostain (1986a, 2003), Tostain *et al.* (1992), Zimmer (2003a), Zimmer & Hilty (1997).

## 65. Amazonian Streaked Antwren

### *Myrmotherula multostriata*

**French:** Myrmidon strié **Spanish:** Hormiguerito Amazónico  
**German:** Amazonien-Strichelameisenschlüpfer

**Taxonomy.** *Myrmotherula multostriata* P. L. Sclater, 1858, Rio Ucayali, Peru.

Considered a sister-species of *M. surinamensis*, and until recently was treated as conspecific with that and also with *M. pacifica*, but vocal and plumage characters indicate that they represent three separate species. Genetic and morphological analyses indicate that all are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. cherriei*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** Locally in E Colombia (Meta), S Venezuela (extreme W Amazonas), and from E Ecuador and NE & E Peru E across C Brazil (E to extreme W Maranhão and N Tocantins, extending N of R Amazon only in area W of lower R Negro and also NE of Manaus) and S to Mato Grosso and NW & NE Bolivia.

**Descriptive notes.** 9-10 cm; 7.5-9 g. Male is black above, streaked white, wing-coverts tipped white, flight-feathers edged white, broad white interscapular patch, tail edged and tipped white; thin black malar streak, white underparts, greyer on flanks and crissum, black streaks from throat to belly and flanks. Barely distinguishable from extremely similar *M. surinamensis*, but tendency for black streaks below to be thinner (variable). Female differs from male in having top of head cinnamon-rufous, crown and nape streaked black, side of head, breast and sides buff, rest of underparts faintly buff-tinged; distinguished from females

of *M. surinamensis* and *M. cherriei* by very thin black malar streak and extensive thin (1 mm wide or less) streaking of underparts. **Voice.** Loudsong an unmusical rattle or trill, first rising in intensity and pitch and then slowing slightly, similar to that of *M. surinamensis* but typically slightly slower in pace. Stereotyped call a rising and falling series of short, song-like notes, differing from that of *M. surinamensis* in that notes are much longer and pace much slower. Call a flat complaining note, often in a doublet with second note shorter.

**Habitat.** Understorey and mid-storey at edges of seasonally flooded lowland evergreen forest (*várzea* and *igapó*) and adjacent shrubby second growth, to 550 m. In most areas, virtually confined to a narrow band of shrubby, vine-tangled vegetation immediately bordering rivers, streams and oxbow lakes.

**Food and Feeding.** Little published. Feeds on small insects, especially small lepidopteran larvae, and spiders. Pairs or individuals forage mostly 1-15 m up in dense foliage and vine tangles overhanging water, often in crowns of more open shrubs and trees with bases submerged in standing water; seldom found more than 50 m away from water's edge. Very active, hitching rapidly from side to side in zigzag progression, twitching wings and tail, frequently retracing its route and scanning foliage for prey as it goes, seldom pausing longer than 1-2 seconds between movements. Most prey perch-gleaned from leaves (particularly from upper surfaces) by reaches or lunging stabs; less frequently, perch-gleans from stem and vine surfaces and makes short, upward-directed fluttering sallies to underside of overhanging vegetation. May briefly join passing mixed-species flocks.

**Breeding.** Jul-Dec in Amazonian Brazil; nest records from Colombia in Jul and Bolivia (Pando) in Jun. Nest described as a small cup or pouch of green mosses and filamentous vegetable matter, decorated with dried leaves (particularly of *Heliconia*) and strands of white fungus-like material, or as a cup woven of blackish fibres heavily decorated with green moss, in each case suspended c. 0.4-3 m above water from fork in slender branch of small tree or shrub growing on bank of river, stream or lagoon. Normal clutch 2 eggs, white, with purple, brownish-purple or blackish spots and streaks concentrated in wreath at blunt end; incubation by both parents during day, presumably only by female at night.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its extensive range. This encompasses vast areas of intact habitat, including several large, protected areas, e.g. Manu National Park and Biosphere Reserve, in Peru, and Serra do Divisor, Jauú and Tapajós National Parks and Cristalino State Park, in Brazil. The bulk of its range has been little affected by development or human colonization. This species' ability to persist in shrubby second-growth habitats makes it less sensitive to disturbance than many other forest species.

**Bibliography.** Cadena, Londoño & Parra (2000), Cory & Hellmayr (1924), Gyldenstolpe (1930b), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. *et al.* (1998, 1999), Isler, P.R. & Whitney (2002), O'Neill & Pearson (1974), Oren & Parker (1997), Parker (2003a), Parker & Remsen (1987), Pinto (1953), Remsen & Parker (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Servat (1996), Sick (1993, 1997), Sneath (1935), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Zimmer, J.T. (1932a), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

## 66. Pacific Antwren

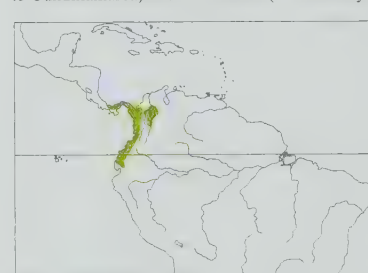

### *Myrmotherula pacifica*

**French:** Myrmidon du Pacifique **Spanish:** Hormiguerito del Pacífico  
**German:** Westlicher Strichelameisenschlüpfer  
**Other common names:** Pacific Streaked Antwren

**Taxonomy.** *Myrmotherula surinamensis pacifica* Hellmayr, 1911, Buenaventura, Valle del Cauca, Colombia.

Until recently considered conspecific with *M. surinamensis* and *M. multostriata*, but vocal and plumage characters indicate that they are separate species; appears to be most closely related to *M. cherriei*. Genetic and morphological analyses indicate that all four species are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** Panama (E from E Bocas del Toro on Caribbean slope, from Panamá on Pacific slope), W & N Colombia (Pacific slope, N base of Andes E to Santander, and Magdalena Valley S to Cundinamarca) and W Ecuador (S to E Guayas, Chimborazo and NW Azuay).

**Descriptive notes.** 9-10 cm; 8.5-10 g. Male is black above, streaked white, wing-coverts tipped white, flight-feathers edged white, white interscapular patch, tail feathers edged and tipped white; thin black malar streak, white throat and underparts, greyer on flanks and crissum, black streaks from throat to belly and flanks. Distinguished from very similar *M. surinamensis* by narrower interscapular patch (less than half distance between scapulars). Female differs from male in having head and upper mantle cinnamon-rufous to buff, crown and nape streaked black, no interscapular patch, no malar streak, breast orange-ochre,

throat and centre of belly pale buff, no streaks below. Subadult male is intermediate between adult male and female. **Voice.** Short series of sharp, unmusical notes that rise slightly in pitch and accelerate slightly. Calls include short scratchy note, often delivered in doublets or triplets, and clearer whistle, also doubled or tripled, notes dropping in pitch and becoming shorter.

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen-forest edge, riparian thickets, and tall, shrubby second growth; to 800 m, occasionally to 1300 m. Typically in second growth and vine-tangled forest borders, often in riparian situations; not found in forest interior, except in light-gaps with dense second growth. Sometimes ventures into adjacent disturbed, more open habitats, such as gardens or plantations.

**Food and Feeding.** Little published. Feeds on small insects and spiders. Pairs or individuals move actively through leafy branches of trees and shrubs, mostly 2-10 m above ground, occasionally down to 1 m or as high as 17 m; progresses by short hops, scanning foliage as it goes, seldom pausing for more than 1-2 seconds between movements. Prey gleaned from leaf, stem and vine surfaces by reaches and by lunging stabs; also by short sallies, these mostly upward and fluttering to undersides of overhanging leaves. May briefly join mixed-species flocks as they pass through its territory.

**Breeding.** Jan-Jul in Panama; a nest in Mar in Colombia. Nest a thin-walled cup of loosely woven green vines, slender filaments resembling aerial rootlets of some epiphytes, or fine grasses, sometimes decorated with leaves or moss, suspended by rim from horizontal fork between two or more narrow branches, often near tip of branch, among foliage 2-6 m above ground. Normal clutch 2 eggs, described as variously greyish-white or white, washed with buff, heavily speckled and mottled with cinnamon-brown, dark brown and lilac-grey, with heavier wreath around larger end and only faintly marked on smaller end, to pale greenish-white without gloss or markings.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its range, which does include several protected areas: examples of these are Soberanía and Darién National Parks, Comarca Kuna Yala Indigenous Reserve and Atlantic Forest (Colón), in Panama, Los Katios National Park, in Colombia, and Rio Palenque Science Centre and Tinalandia, in Ecuador. Occupies a

variety of shrubby forest-edge and second-growth habitats, making it less sensitive than most antbirds to human disturbance.

**Bibliography.** Cory & Hellmayr (1924), Eisenmann (1952), Gyldenstolpe (1930b), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler, M.L. *et al.* (1999), Isler, P.R. & Whitney (2002), Oates & Reid (1903), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Sclater & Salvin (1879), Stone (1918), Stotz *et al.* (1996), Wetmore (1972), Zimmer (2003a).

## 67. Cherrie's Antwren

### *Myrmotherula cherriei*

**French:** Myrmidon de Cherrie

**Spanish:** Hormiguerito de Cherrie

**German:** Weißstreifen-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula cherriei* Berlepsch and Hartert, 1902, Puerto Ayacucho, Amazonas, Venezuela.

Appears to be most closely related to *M. pacifica*. Genetic and morphological analyses indicate that both species are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. klagesi*, *M. longicauda*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** SE Colombia (E Vichada, Meta, Guianá, Caquetá), SW Venezuela (Amazonas), NE Peru (Loreto N of R Marañón) and NW Brazil (R Negro drainage).

**Descriptive notes.** 9-10 cm; 7.5-9 g. Male is black above, streaked white, wing-coverts tipped white, flight-feathers edged white, white interscapular patch, tail feathers edged and tipped white; indistinct black malar streak, white throat and underparts, greyer on flanks and crissum, black streaks from throat to belly and flanks. Distinguished from very similar *M. surinamensis* by much narrower interscapular patch (less than half distance between scapulars). Female differs from male in having head streaks pale buff, no interscapular patch, pale buff underparts with streaks slightly thinner (1.5-2 mm wide on breast, narrower below). Subadult male

is intermediate between adult male and female. **VOICE.** Loudsong an unmusical rattle, similar to that of *M. surinamensis* and *M. multistriata* but pitch rises more noticeably throughout and pace remains constant. Call a downslurred emphatic "tchew" (unique among the "streaked antwrens").

**Habitat.** Understorey and mid-storey of stunted, poorly drained woodland on white-sand soils; to 550 m, one record at 800 m. In some areas also in dense thickets and palm-filled borders of seasonally flooded gallery forest in savanna regions, these often occurring as "islands" of trees dissected by small streams. Also ranges from savanna woodland and shrubby borders into adjacent taller *várzea* forest at ecotones. Appears confined to shrubby thickets that border island lagoons and sandbars in the Anavilhanas Archipelago of R Negro (Brazil), and to borders of streams and lagoons in N Peru.

**Food and Feeding.** Not well known. Feeds on variety of small insects, particularly small lepidopteran larvae; also spiders. Forages as closely associated pair-members, or singly, mostly 1-7 m above ground (ascending to 10 m or more in taller forest), flicking wings constantly and hitching rapidly from side to side through thin, leafy branches and hanging vines. Perch-gleans from live leaves and vines by reaches or lunging stabs, or making short (to 15 cm) jumping sallies to undersides of overhanging leaves. Often joins mixed-species flocks; in Venezuela, frequent flock associates include *Thamophilus amazonicus*, *Sakesphorus canadensis*, *Formicivora grisea*, Yellow-breasted Flycatcher (*Tolmomyias flaviventris*), Brown-headed Greenlet (*Hylophilus brunneiceps*), Tropical Gnatcatcher (*Poliotila plumbea*), and a variety of honeycreepers and tanagers (Thraupidae); in Jaú National Park, in Brazil, frequent associates include *Hypocnemoides melanopogon*, Tropical Gnatcatcher (*Poliotila plumbea*) and Grey-chested Greenlet (*Hylophilus semicinctus*).

**Breeding.** Little known. Nest found in Brazil (Jaú) in Sept (details previously unpublished): described as a pendent bag or cup c. 6 cm deep and 4 cm wide, constructed of unidentified plant materials, placed c. 3 m off ground in 4-m tree at edge of a large flooded area (within 5 m of water's edge) in low-stature woodland with essentially no understorey and rather openly spaced, mostly thin-trunked trees 4-7 m tall (known locally as *chavascal*); female seen leaving nest, and male carrying food nearby. Another nest, observed in Apr in Colombia (Meta), was on a low dead limb hanging over water.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common, although patchily distributed throughout its range. Some large protected areas exist within its range, e.g. Yacapana National Park and adjacent indigenous reserves, in Venezuela, Rio Negro State Park and Jaú National Park, in Brazil, and Allpahuayo-Mishana Reserved Zone, in Peru. The recent discovery of this species in the Anavilhanas Archipelago and the expansive (22,720 km<sup>2</sup>) Jaú National Park extends considerably its known range. In Venezuela and NW Brazil, the sandy-soil habitats and *igapó* scrub occupied by this little-known thamnophilid are currently among the areas of Amazonia that have been least settled and least affected by humans. The situation is different in NE Peru, where sandy-soil habitats are being heavily exploited by expanding human populations.

**Bibliography.** Álvarez (1994), Borges *et al.* (2001), Cory & Hellmayr (1924), Gyldenstolpe (1930), Hackett & Rosenberg (1990), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. *et al.* (1998, 1999), Isler, P.R. & Whitney (2002), Ridgely & Tudor (1994), Sick (1993), Stiles *et al.* (1995), Stotz *et al.* (1996), Whitney & Cohn-Haft (2003), Zimmer (2003a), Zimmer & Hilty (1997).

## 68. Klages's Antwren

### *Myrmotherula klagesi*

**French:** Myrmidon de Klages

**Spanish:** Hormiguerito de Klages

**German:** Rio Negro-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula klagesi* Todd, 1927, Santarém, Pará, Brazil.

Vocalizations suggest that this and *M. longicauda* are sister-species. Genetic and morphological analyses indicate that both species are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** C Amazonian Brazil on extreme lower R Branco, lower R Negro and E along R Amazon, including lower R Madeira, to mouth of R Tapajós.

**Descriptive notes.** 9-10 cm; 7.5-8.5 g. Male is black above, streaked white, wing-coverts tipped white, flight-feathers edged white, tail (only 10 feathers) edged and tipped white; indistinct black malar streak, white throat and underparts, greyer on flanks and crissum, black streaks from throat to belly and flanks. Distinguished from very similar *M. surinamensis* by lack of white interscapular patch, 10 (rather than 12) rectrices. Female differs from male in having head and upperpart streaks pale buff, underparts buff, slightly darker on breast, with streaks shorter and confined to breast and sides (sometimes extending faintly to throat and

middle of belly). **VOICE.** Loudsong a series of paired notes, second note shorter and almost always higher-pitched than first (sometimes only one of the two is given), repeated at same pitch and pace, number of pairs varies, often six. Calls include pair of abrupt notes, second lower-pitched, and long, somewhat downslurred whistle.

**Habitat.** Canopy and subcanopy of seasonally flooded (*igapó* and *várzea*) lowland evergreen forest, to 100 m. Favours river-edge forest, perhaps especially on river islands. Although primarily an occupant of higher forest strata, routinely descends much lower at edges.

**Food and Feeding.** Nothing published. Feeds on lepidopteran larvae, various small orthopterans, mantids, true bugs (Hemiptera) and other insects; also spiders. Forages in pairs or individually, mostly in dense foliage, particularly where overlapping vine tangles and leafy canopies of understorey and mid-storey trees form mats of vegetation, these most commonly overhanging water at forest edge. Typically in canopy or subcanopy (to 20 m or more); at forest edges and light-gaps within forest utilizes all levels, frequently descending to within 2-3 m (occasionally lower) of ground or water. Forages actively, progressing by short hops, with only brief pauses (usually 1 second or less) to scan for prey; typically, moves rapidly through vegetation on irregular, zigzag path, hitching from side to side along slender horizontal and vertical branches and vines, habitually flicking both wings, and usually working individual trees or shrubs methodically before moving on. Prey most frequently perch-gleaned from live leaves (particularly from undersides), stems or vines by lunging stabs or reaches, these usually upward-directed, with legs extended and neck stretched; capture typically accompanied by an audible snap of mandibles. Also regularly makes short, upward-directed sallies to hover-glean or flutter-glean items from underside of overhanging vegetation, before dropping back to near original perch; less frequently longer sallies (to c. 1 m) without hovering or fluttering at point of capture, then continuing on to new perch. Often flutters rapidly downwards through several layers of foliage to pursue flushed or dislodged prey. Regularly accompanies mixed-species flocks of other insectivores.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Amazon Flooded Forests EBA. The species is fairly common to common throughout much of the extensive river-island system that comprises the Anavilhanas Archipelago, and this area is formally protected as the Anavilhanas Ecological Station (3350 km<sup>2</sup>), which falls within the Rio Negro State Park (4360 km<sup>2</sup>). These areas are large, mostly pristine, and under little threat; as such, they protect a large, viable population of the species. The small range of this thamnophilid is, however, a cause for concern. Although the species is probably widespread on river islands with appropriate habitat from the mouth of R Negro to the mouth of R Tapajós, there have been few recent surveys in these areas. More survey work is needed in order to locate any additional populations of this species, including in the Santarém region from which the historical records originate.

**Bibliography.** Cohn-Haft (2003b), Cohn-Haft & Whitney (2003a), Collar *et al.* (1994), Gyldenstolpe (1930b), Hackett & Rosenberg (1990), Isler & Whitney (2002), Ridgely & Tudor (1994), Sick (1993), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whittaker (2003a), Zimmer (2003a).

## 69. Stripe-chested Antwren

### *Myrmotherula longicauda*

**French:** Myrmidon à ventre blanc

**Spanish:** Hormiguerito Pechilistado

**German:** Weißbauch-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula longicauda* Berlepsch and Stolzmann, 1894, Chontabamba, La Merced and La Gloria, Junín, Peru.

Vocalizations suggest that this and *M. klagesi* are sister-species. Genetic and morphological analyses indicate that both are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. sclateri* and *M. ambigua* (the "streaked antwren assemblage"). Plumage distinctions among races are not entirely clear, and ranges listed below are tentative; further, taxonomic status of recently discovered population inhabiting lowland flooded forest in Loreto (Peru) uncertain; further study required. Four subspecies recognized.

**Subspecies and Distribution.**

*M. l. soderstromi* Gyldenstolpe, 1930 - E slope of Andes in S Colombia (Putumayo) and N Ecuador (Napo).

*M. l. pseudoaustralis* Gyldenstolpe, 1930 - E slope in S Ecuador (Morona-Santiago, Zamora-Chinchepe) and N Peru (S to Pasco).

*M. l. longicauda* Berlepsch & Stolzmann, 1894 - C Peru (Junín).

*M. l. australis* Chapman, 1923 - SE Peru (Cuzco, Madre de Dios, Puno) and NW Bolivia (La Paz, S Beni, Cochabamba).

**Descriptive notes.** 9-10 cm; 8-9.5 g. Male is black above, streaked white, wing-coverts tipped white, flight-feathers edged white, tail (only 10 feathers) edged and tipped white; distinct black malar streak, white below, greyer on flanks and crissum, black streaks on breast and flanks. Distinguished from very similar *M. surinamensis* by more distinct malar stripe, lack of white interscapular patch, underpart streaking in more distinct band across breast, 10 (rather than 12) rectrices. Female differs from male in having pale streaks, tips and edgings above often buff-tinged, throat and underparts pale buff, more ochraceous across breast, thinner black streaks on sides but no or few faint spots or streaks on breast centre. Races

differ from nominate in plumage of female; *australis* is deeper ochraceous buff throughout, especially surrounding upperpart streaks and on breast; *pseudoaustralis* is similar to previous but wingbars very pale; *soderstromi* is also similar but has belly white. VOICE. Loudsong a series of paired notes, second note usually lower in pitch than first, repeated variable number of times, overall pitch typically higher than that of *M. klagesi*. Calls include clear long whistle, sharply downslurred and then flattening out, often immediately preceded by 1-3 abrupt notes, also abrupt notes given singly or in pairs, very different from *M. klagesi*.  
**Habitat.** Understorey and mid-storey of foothill and lower montane evergreen-forest edge and second-growth woodland; primarily in foothills, mostly at 400-1300 m, but ranges as high as 1800 m, and occurs locally near base of Andes down to 150 m. Favours shrubby forest borders, regenerating clearings, and swampy, riparian thickets. Recently discovered lowland population in Peru (Pacaya-Samiria National Reserve, in Loreto) inhabits permanently flooded stunted forest, 5-6 m tall, with stagnant bodies of black water.

**Food and Feeding.** Little published. Feeds on small insects and spiders. Forages in pairs or individually, 1-15 m above ground, mostly 2-8 m, in shrubby thickets, leafy crowns of understorey saplings, and mid-storey vine tangles, occasionally in dead-leaf clusters. Very active, hitching from side to side in zigzag progression, scanning foliage as it goes, seldom pausing for more than 1-2 seconds between hops. Prey gleaned from leaf, stem and vine surfaces by reaches, lunging stabs, and short, mostly upward-directed, fluttering sallies. Frequently alone, but often in mixed-species flocks, at lower elevational limits mainly of other antwrens and foliage-gleaners (Fumariidae), but at higher elevations often with flocks dominated by tanagers (Thraupidae) and tyrant-flycatchers (Tyrannidae).

**Breeding.** Nothing known.  
**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its reasonably large range. This includes some large protected areas, e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru; also many smaller ones, particularly in E Ecuador. In Peru, was considered to be locally fairly common in the large (2,080,000 ha) Pacaya-Samiria National Reserve, where the lowland flooded-forest habitat occupied by this disjunct population is atypical for the species. In general, the lower Andean slopes to which this species is mostly restricted are some of the areas most at risk from deforestation and cultivation by an ever-expanding human population; even common species should, therefore, be considered at some risk and worthy of monitoring. The species' ability to tolerate forest-edge and second-growth woodland renders it less sensitive to human disturbance than many other antbirds.

**Bibliography.** Begoza & Valqui (1998), Cory & Hellmayr (1924), Foster *et al.* (1994), Gylstenstolpe (1930b), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler, M.L. *et al.* (1999), Isler, P.R. & Whitney (2002), Parker (2003a), Parker & Bailey (1991), Perry *et al.* (1997), Remsen & Parker (1984), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Zimmer, J.T. (1932a), Zimmer, K.J. (2003a).

70. Sclater's Antwren  
*Myrmotherula sclateri*

French: Myrmidon de Sclater Spanish: Hormiguerito de Sclater  
German: Gelbstreifen-Ameisenschlupfer

**Taxonomy.** *Myrmotherula sclateri* Sneath, 1912, Boim, Rio Tapajós, Pará, Brazil.  
Forms a superspecies with *M. ambigua*. Genetic and morphological analyses indicate that both species are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. klagesi* and *M. longicauda* (the "streaked antwren assemblage"). Form described as *M. kermiti* ("Kermit's Antwren") was based on variants of present species. Monotypic.  
**Distribution.** E Peru (S of R Amazon, E of R Ucayali), S Amazonian Brazil (E to lower R Xingu and S to N Mato Grosso) and NW & NE Bolivia (Pando, N La Paz, NE Santa Cruz).

**Descriptive notes.** 8-8.5 cm; 8-10 g. Male is black above, crown streaked light yellow, upperparts streaked whitish, light yellow interscapular patch, two prominent white wingbars, tail feathers edged white, narrowly tipped white; cheeks to breast yellow, prominent black malar streak, rest of underparts paler, few black streaks on breast sides. Female is similar to male, but pale colours on head and breast often more ochraceous, and usually more streaks below; some individuals, especially in S Amazonia, vary in amount of streaking on underparts (sometimes limited to sides), intensity of ochraceous colour on head,

and blackness of crown streaks ("Kermit's Antwren"). VOICE. Loudsong a long, somewhat mournful note slowly repeated (e.g. 5 notes, 3-8 seconds) at even pace and pitch, notes slightly shorter than spaces between them.

**Habitat.** Canopy of lowland evergreen forest (*terra firme*, *várzea*, transitional), to 550 m. Less of an edge bird than sympatric *M. brachyura*, and more indicative of continuous forest.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae and katydids (Tettigoniidae); probably also spiders. Usually encountered as closely associated pair-members or family groups, almost always with large mixed-species canopy flocks of tanagers (Thraupidae), furnariids, tyrant-flycatchers (Tyrannidae) and other insectivores. Forages mostly from 15 m above ground (sometimes descending lower at forest edges) up to the canopy, most often in small leaves and branches of upper canopy (like *Terenura*); mean foraging height at a site in Brazil was 17.9 m; on average, forages higher up than does *M. brachyura*, which often found in same flocks. Hops rapidly through vegetation, often along thin horizontal branches, flashing the

yellow interscapular patch, perch-gleaning prey from leaf surfaces, less often from twigs and vines, with quick bill-stabbing motions and lunges; also makes short sallies and hover-gleans. Occasionally works the same dense vine tangles in interior canopy as are favoured by *M. brachyura*. Appears to be the ecological counterpart of *M. ambigua*.

**Breeding.** Little known. In Bolivia (Pando), pair observed feeding two recently fledged young on 18 Jun, and other family groups of 3-4 birds reported in Jun-Aug. Territory apparently much larger than that of *M. brachyura*, possibly encompassing range of the flocks which it habitually follows.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common throughout its rather extensive range, which includes several large protected areas. Examples of these are Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks, in Bolivia, and Serra do Divisor, Pacaás Novos and Tapajós National Parks and Cristalino State Park, in Brazil. In addition, extensive intact habitat remains which, although not formally protected, appears to be at little near-term risk of development.

**Bibliography.** Alverson *et al.* (2000), Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Isler, M.L. *et al.* (1999), Isler, P.R. & Whitney (2002), Munn (1984, 1985), O'Neill (1969), Oren & Parker (1997), Parker (1982, 2003a), Parker & Bailey (1991), Parker & Remsen (1987), Parker *et al.* (1991), Remsen (1986), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg (2003), Servat (1996), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1990), Zimmer, J.T. (1932a), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

71. Yellow-throated Antwren  
*Myrmotherula ambigua*

French: Myrmidon à gorge jaune Spanish: Hormiguerito Gorgiamarillo  
German: Gelbkehl-Ameisenschlupfer

**Taxonomy.** *Myrmotherula ambigua* J. T. Zimmer, 1932, Mount Duida, 500 feet [c. 150 m], Amazonas, Venezuela.

Forms a superspecies with *M. sclateri*. Genetic and morphological analyses indicate that both are part of a monophyletic group that also includes *M. brachyura*, *M. ignota*, *M. surinamensis*, *M. multistriata*, *M. pacifica*, *M. cherriei*, *M. klagesi* and *M. longicauda* (the "streaked antwren assemblage"). Monotypic.

**Distribution.** SW Venezuela (S Amazonas), extreme E Colombia (Guainía, Vaupés) and NW Brazil (upper R Negro region E to NC Roraima and S to Jaú).

**Descriptive notes.** 8-8.5 cm; 7-8 g. Male is black above, streaked white, light yellow interscapular patch, rump greyish, two prominent white wingbars, tail feathers edged white, narrowly tipped white; cheeks whitish, underparts light yellow, black malar streak, some black streaks on sides. Distinguished from very similar *M. sclateri* by having crown and nape streaks white, rump grey, malar streak less prominent. Female is similar to male, but pale colours on head and breast tawny-buff to buff, interscapular patch minimal or absent. VOICE. Loudsong an evenly paced and evenly pitched series like that of *M. sclateri*, but notes much

shorter and downslurred, overall pace much faster (e.g. 8 notes, 4-4 seconds).

**Habitat.** Canopy and subcanopy of lowland evergreen forest, mostly below 350 m; occasionally to c. 1100 m on sides of tepuis. Found in variety of forest types that occur on white-sand soils, and which have been referred to collectively as "Amazonian *caatinga*"; these include lower-stature, less floristically diverse forest on purer sandy soils, as well as high-canopied (35 m or more), more diverse forest on mixed soils.

**Food and Feeding.** Not well known. Feeds on various small insects; probably also on spiders and other arthropods. Usually encountered as closely associated pair-members, and almost always associated with mixed-species canopy flocks of furnariids, tyrant-flycatchers (Tyrannidae), tanagers (Thraupidae) and other insectivores. Often in same flocks as *M. brachyura*. Roams the highest parts of the canopy, hopping rapidly through smaller branches and terminal foliage, where it perch-gleans prey from leaf (primarily), branch and vine surfaces with darting stabs, and hover-gleans. Also works vine tangles and smaller epiphytes in interior of canopy, occasionally descending to mid-storey along clusters of hanging vines adjacent to trunks. In stunted white-sand forest, regularly feeds as low as 10-15 m, these heights still constituting the canopy and subcanopy. Appears to be the ecological counterpart of *M. sclateri*.

**Breeding.** Nothing known.  
**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Orinoco-Negro White-sand Forests EBA. Uncommon to fairly common. Its relatively small range does include some large protected areas, e.g. La Neblina National Park and possibly the Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Pico da Neblina and Jaú National Parks, in Brazil; also vast contiguous areas of intact habitat which are not formally protected, but are under little or no current threat. Regardless of decrees, even areas that are "officially" protected in this region are affected to varying degrees by illegal mining operations; on the broad scale, however, the impact is relatively minimal, and the region in which this species occurs remains one of those that has been least affected by humans in South America.

## 72. Rufous-bellied Antwren

### *Myrmotherula guttata*

French: Myrmidon moucheté

Spanish: Hormiguerito Ventrirrufo

German: Rostbauch-Ameisenschlüpfer

**Taxonomy.** *Myrmothera guttata* Vieillot, 1825, Cayenne.

Forms a superspecies with *M. huxwelli*, but their relationship to other groups in the genus is uncertain. Monotypic.

**Distribution.** S Venezuela (Bolívar, Amazonas), the Guianas and NE Amazonian Brazil (from E of R Negro E to Amapá).

**Descriptive notes.** 8.5-9.5 cm; 8.5-11 g. Tail short, making body appear disproportionately large. Male is mostly grey, with throat paler, interscapular patch white, pale cinnamon spots on uppertail-coverts; wings and tail blackish-brown, remiges edged cinnamon, pale cinnamon tips of wing-coverts, spots on tertials, tip of tail; lower belly, flanks and crissum tawny. Differs from *M. huxwelli* in tawny lower underparts, cinnamon (not white) spots and edgings above. Female is like male, except upperparts olive-grey, anterior underparts greyish-olive. **VOICE.** Loudsong a long, countable series (e.g. 17 notes, 9 seconds) of whistles that gains in intensity and rises slightly in pitch while notes become shorter and more downslurred. Other vocalizations include short (e.g. 0-1 seconds), ascending rattle-like call repeated irregularly or rapidly in series, and short (e.g. 0-4 seconds), slightly downpitched rattle.

**Habitat.** Understorey of lowland evergreen forest, to 600 m, occasionally higher. Primarily in *terra firme* forest, especially in zones having a high density of slender vertical stems and saplings and a well-developed leaf litter. Often in proximity of sluggish streams or poorly drained low spots in forest. Apart from its liking for wet areas, seems to be the ecological counterpart of *M. huxwelli*.

**Food and Feeding.** Little published. Stomach contents of specimens from Surinam included a variety of lepidopteran larvae, orthopterans (Tettigoniidae), hymenopterans (Formicidae), true bugs (Hemiptera: Homoptera: Jassidae), and spiders. Forages in pairs or individually, mostly within 1 m of ground, rarely to 2 m, clinging laterally to slender vertical stems; tends to hitch vertically up these, with little investigation of lateral branches, before flitting to another stem. During foraging, lowers the tail slowly and flicks it up to line of body; displays white interscapular patch in aggressive posture. Gleans prey from leaf, stem and branch surfaces by lunging stabs or reaches; also frequently by short, upward-directed, fluttering sallies to undersides of leaves, and by darting sally-pounces to snatch prey from surface of leaf litter. Sometimes probes curled dead leaves suspended above ground, but just as frequently ignores them. Usually encountered apart from mixed-species flocks, but often joins these as they pass through, dropping out as the flock moves beyond its territory. Documented as occasionally following army ants (in Brazil, Guyana, Surinam), sometimes for up to 2 hours, searching widely rather than waiting intently.

**Breeding.** In French Guiana, two nests in Sept (details previously unpublished) and other families seen in Sept-Dec; in Surinam, fledgling just out of nest in Oct and another accompanied by parents in Aug. In French Guiana, nest a fairly deep cup, built 33-45 cm above ground, in one case located just under large leaf of young palm (*Astrocaryum sciophilum*); 2 eggs, white with violaceous-brown lines. **Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common. Species' range includes some large protected areas, e.g. Canaima, La Neblina and Jaua-Sarisaríama National Parks and the Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam; also encompasses vast contiguous areas of intact habitat which, although not formally protected, are under little or no current threat of development.

**Bibliography.** Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Isler & Whitney (2002), Mason (1996), Meyer de Schauensee & Phelps (1978), Moskovits *et al.* (1985), Novaes (1980), Oniki & Willis (1972), Powell (1989), Reynaud (1998), Ridgely & Tudor (1994), Sick (1993), Snyder (1966), Stotz (1990b), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Stouffer & Bierregaard (1995), Thiollay (1988a, 1994), Tostain (2003), Tostain *et al.* (1992), Willard *et al.* (1991), Willis (1977, 1984a), Zimmer (2003a).

## 73. Plain-throated Antwren

### *Myrmotherula huxwelli*

French: Myrmidon de Hauxwell

Spanish: Hormiguerito de Hauxwell

German: Graubauch-Ameisenschlüpfer

**Taxonomy.** *Formicivora huxwelli* P. L. Slater, 1857, Chamicuro, Loreto, Peru.

Forms a superspecies with *M. guttata*, but their relationship to other groups in the genus is uncertain. Described race *clarior* (C. Brazil) appears to intergrade clinally with nominate and is merged with it, pending further study. Three subspecies recognized.

**Subspecies and Distribution.**

*M. h. suffusa* J. T. Zimmer, 1932 - SE Colombia (from Meta S along base of Andes, E to E Vaupés), extreme NW Amazonian Brazil (W of R Japurá), E Ecuador and NE Peru (Loreto and Amazonas N of R Marañón).

*M. h. huxwelli* (P. L. Slater, 1857) - E Peru (S of R Amazon and R Marañón), SW & SC Amazonian Brazil (E to R Xingu in Pará, S to Acre and SW & N Mato Grosso) and NW & NE Bolivia (Pando, Beni, La Paz, NE Santa Cruz).

*M. h. hellmayri* Sneathley, 1906 - E of R Xingu in E Pará and W Maranhão.

**Descriptive notes.** 8.5-9.5 cm; 9-12 g. Tail short, making body appear disproportionately large. Male is mostly grey, paler below, throat whitish; white interscapular patch, white spots on uppertail-coverts; wings and tail blackish-brown, remiges edged white, small white spots on tertials, white tips of wing-coverts, tail tipped white. Distinguished from *M. guttata* by grey posterior underparts, white (not cinnamon) spots and edgings above, spots smaller. Female has upperparts washed cin-

namon-rufous, remiges edged dull cinnamon, underparts tawny-cinnamon except throat paler, sides and flanks tinged olive. Juvenile resembles female but more olive throughout, contrasting pale throat. Race *suffusa* male has spots smaller than nominate, female darker; *hellmayri* lacks interscapular patch, male is paler, female is darker, especially on underparts, with more sharply contrasting whitish throat. **VOICE.** Loudsong a long, countable series (e.g. 20 notes, 8-4 seconds; duration highly variable) in which initial notes sound more musical and higher-pitched, remaining notes become shorter and more hollow-sounding, irregularly, often doubled; also short (e.g. 0-1 seconds), descending rattle-like call, and a rattle similar to that of *M. guttata*.

first speeding up and then becoming evenly paced. Other vocalizations include abrupt "jit" given irregularly, often doubled; also short (e.g. 0-1 seconds), descending rattle-like call, and a rattle similar to that of *M. guttata*.

**Habitat.** Understorey of lowland evergreen forest (*terra firme*, *várzea*/igapó, transitional), mostly below 600 m, rarely to 900 m. More common in *terra firme* forest, particularly where undergrowth is well shaded and there is a moderate density of slender vertical stems and saplings (particularly small palms), fallen branches, and well-developed leaf litter. In many respects the ecological counterpart of *M. guttata*, but present species appears not to have an affinity for streams or swampy ground. Race *hellmayri* occurs in second growth, as well as primary forest.

**Food and Feeding.** Feeds on insects and other arthropods; also, perhaps opportunistically, on small lizards. Analysis of stomach contents of nine Peruvian specimens showed orthopterans to be commonest prey, followed in order by beetles (Coleoptera), spiders, ants (Formicidae), larvae (probably primarily lepidopteran), heteropterans, flies/wasps, and cockroaches (Blattidae). In one prey-selectivity experiment, using birds in outdoor cages, harvestmen (Opiliones) were rejected, but butterflies (Lepidoptera) and dragonflies (Odonata) readily captured and consumed; one bird also captured a 5-cm lizard, which it beat on a branch and then swallowed whole. Forages in pairs or individually, mostly within 1 m of ground, rarely to 3 m up; in 84 observations in Peru (Cocha Cashu), mean foraging height was 0-3 m. Clings laterally to slender vertical stems, tending to hitch vertically up these, with little investigation of lateral branches, before flitting to another stem; also sometimes hitches short distances up philodendrons (*Philodendron*) and other large-leaved vines clinging to base of larger-trunked trees. During foraging, tail is lowered slowly and flicked up to line of body or higher. Gleans prey from leaf, stem and branch surfaces by lunging stabs or reaches (mostly upwards), with neck extended while clinging with feet; also frequently by short, upward-directed fluttering sallies to undersides of leaves. Also makes darting sally-pounces to snatch prey from surface of leaf litter, and frequently hops on ground and picks through litter for several seconds at a time before hopping back up to a vertical perch. Commonly probes curled dead leaves suspended above ground, but just as frequently ignores them; in a study in Peru/Bolivia, dead leaves comprised 50% of foraging substrates out of 70 observations. Usually encountered apart from mixed-species flocks, but often joins these as they pass through its territory, dropping out as the flock moves beyond; participation in mixed flocks may be more common in race *hellmayri*. In some areas regularly follows army ants (*Eciton rapax*, *E. burchelli*, *Labidus praedator*), usually remaining at periphery of swarm if it is attended by obligate followers such as *Phlegopsis* or *Rhegmatorhina* species; takes low perches (mostly below 0-5 m) over the ants, usually clinging laterally to slender vertical saplings or stems, sometimes to root buttresses, and perch-gleans by reaching, or makes short darting sallies to ground, stems, vines and foliage. Ant-following recorded from Ecuador, Peru and Brazil, and perhaps most common in race *hellmayri*; in the Alta Floresta region of Mato Grosso (Brazil), where nominate race is common, ant-following was not noted despite many hours of observation at numerous ant swarms.

**Breeding.** Nests recorded in Nov-Feb in Brazil, but young fledglings seen in Apr-Aug in E (Belém); single nest in Oct in Ecuador. One nest in Brazil a cup 5-5 cm in external diameter and 4 cm deep, made exclusively of blackish, horsehair-like rootlets, sturdy yet loosely woven (contents visible from below), suspended from fork between two fine branches, another was 80-90 cm above ground at end of branch in small tree; Ecuador nest a small, thin cup, suspended between two upright twigs 20 cm above ground. Normal clutch probably 2 eggs, light pinkish with irregularly distributed brownish or vinaceous spots and streaks; incubation confirmed only for female, but probably by both parents.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its large range. This includes a number of large protected areas, such as Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Serra do Divisor, Picaás Novos and Tapajós National Parks, Cristalino State Park and Caxiuanã National Forest, in Brazil, and Madidi and Noel Kempff Mercado National Parks, in Bolivia. In addition, the species' range encompasses vast contiguous areas of intact habitat which, although not formally protected, are under little or no current threat of development.

**Bibliography.** Álvarez (1994), Alverson *et al.* (2000), Bates *et al.* (1999), Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler & Whitney (2002), Munn (1984, 1985), Munn & Terborgh (1979), Novaes (1969, 1970, 1973), Oniki (1971b, 1972a), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Parker *et al.* (1982), Pearson (1977a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg, K.V. (1932a), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

## 74. Star-throated Antwren

### *Myrmotherula gularis*

French: Myrmidon à gorge étoilée

German: Perlenkehl-Ameisenschlüpfer

Spanish: Hormiguerito Gorgipinto

**Taxonomy.** *Thamnophilus gularis* Spix, 1825, no locality = Rio de Janeiro, Brazil.

Relationships uncertain; often placed with the *M. haematonta* group (the "stipple-throated antwren assemblage") because of its dotted throat, but that placement is put in question by the finding of a

cup rather than globular nest; also, its behaviour suggests that it may be related to *M. gutturalis* and *M. hauxwelli*; its vocalizations appear to be intermediate. Monotypic.

**Distribution.** SE Brazil in coastal region from S Bahia S to Santa Catarina and N Rio Grande do Sul, extending inland in S to W Paraná.

**Descriptive notes.** 8.5-9.5 cm; 10-12 g. Male has forehead greyish, crown, upperparts, remiges and tail rufous-brown; hidden white interscapular patch; wing-coverts blackish-brown, greater and median coverts dotted pale cinnamon, bend of wing edged white; throat black, spotted white, breast and belly grey, flanks and crissum pale rufous-brown. Female differs from male in having forehead buffy, white throat spots larger, no interscapular patch. **VOICE.** Loudsong a short (e.g. 8 notes, 2-4 seconds), evenly paced, countable series of harsh downslurred notes, intensity increasing initially, pitch decreasing terminally.

Other vocalizations include brief, harsh notes; a short, flat rattle-like call (individual elements not distinct), sometimes in series of 3-4; and a short (e.g. 0.5 seconds) rattle (individual notes distinct).

**Habitat.** Understorey of evergreen forest, to 1550 m; in most areas found above 300 m, but occurs down to near sea-level at base of the Serra do Mar. Favours dense vegetation and tangles, especially along sluggish forest streams (lowlands) and shaded ravines (mountainsides).

**Food and Feeding.** Little published. Feeds on a variety of small insects, including crickets (Gryllidae), grasshoppers (Acrididae), hemipterans, and lepidopteran larvae; also spiders. Forages in pairs or individually, mostly 0-5 m above ground, rarely to 8 m, moving actively but not usually hurriedly, and routinely flicking both wings. In intraspecific displays, males face each other c. 15 cm apart, with wings played to show white spots. Most commonly forages within a few centimetres of ground, clinging laterally to slender vertical stems, ferns, palmettos and saplings, alternating between upward-reaching perch-gleans and short jumping sallies to undersides of leaves; also sally-pounces to snatch prey from surface of leaf litter, and hops on fallen logs and surface debris. In addition, regularly works through fallen branches and through shaded understorey trees, where it scans both live and dead leaves; often (but not habitually) pauses to probe the latter, typically for 1-4 seconds, occasionally longer. When foraging more than 1 m above ground, most often hitches up through vine tangles or along central portions of trees, avoiding terminal branches, and often probing in tufts of moss on trunks and larger branches. Also gleans from bare-stem, branch and vine surfaces. Generally alone, but sometimes in company of mixed-species understorey flocks at lowland elevations, where often with Red-crowned Ant-tanagers (*Habia rubica*), foliage-gleaners (Furnariidae) and other thamnophilids. One published record of a pair following army ants (*Labidus praedator*) for 1 hour through dense growth near a treefall.

**Breeding.** Three previously unpublished nests, found in Nov in São Paulo, Paraná and Santa Catarina, were located 0.6-1.0 m off the ground in shrubs hanging over or adjacent to watercourses that flowed through tall (c. 20 m high) forest. Nests were cup-shaped, and built amongst several thin branches or placed in a branch fork; nests were c. 7 cm in diameter (one widening to 9.5 in one direction) and 6.0-8.0 cm high, constructed of roots and *Marasmium* fungal strands; no dead leaves were hung from nests but fresh green moss placed around one. Both parents carried food to the nest. Eggs have been described as white, with very fine, barely needle-stitch-sized brown spots that condense into a wreath on blunt end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Generally uncommon. No recent records from W Paraná and N Rio Grande do Sul, where recorded historically. Although not currently threatened, its populations should be monitored for signs of decline. Less than 20% of original forest in the region remains; although this species occurs in a number of well-protected parks and reserves, e.g. Itatiaia, Serra dos Órgãos and Serra da Bocaina National Parks, and Serra do Mar and Desengano State Parks, other reserves lack the manpower and infrastructure for adequate protection. The enforced protection of all existing parks and reserves should ensure the continued viability of this species. Even so, the deforestation, colonization, agricultural expansion and urbanization that inevitably follow an expanding human population in this already most densely populated region of Brazil will present continuing threats to the integrity of the reserves on which this and many other endemic species depend.

## 75. Brown-bellied Antwren

### *Myrmotherula gutturalis*

**French:** Myrmidon à ventre brun

**Spanish:** Hormiguerito Ventripardo

**German:** Braunbauch-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula gutturalis* P. L. Selater and Salvin, 1881, Bartica, Guyana.

Genetic, morphological and behavioural analyses indicate that this species is part of a monophyletic group that also includes *M. fulviventr*, *M. leucophthalma*, *M. spodiota*, *M. haematona*, *M. feldsaai*, *M. ornata* and *M. erythrura* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. Monotypic.

**Distribution.** E Venezuela (Bolívar E of R Caroni), the Guianas and NE Amazonian Brazil (E of R Branco and lower R Negro).

**Descriptive notes.** 9.5-10.5 cm; 7.5-9.5 g. Male is olive-brown above, wing-coverts darker with small white (sometimes pink-tinged) tips; throat black, spotted white; head side, breast and upper belly grey, posterior underparts become grey with clay-coloured tinge. Female has crown and upperparts yellowish olive-brown, remiges and tail reddish, wing-coverts tips tinged pink or pinkish-buff,

throat pale buff, underparts pale brownish-buff, darker on flanks and crissum. Juvenile male has shorter tail than adult, large wing spots almost forming a band. **VOICE.** Loudsong a very rapid, high-pitched, musical trill of abrupt notes initially ascending sharply in pitch and intensity, then gradually dropping in pitch, length variable (typically 1.5-3 seconds). Calls include distinctive "chip" followed by a series of c. 5 notes that rise and fall in pitch and intensity; also single downslurred note, and rubbery rattle rising and falling in pitch and intensity.

**Habitat.** Understorey of lowland and foothill evergreen forest (*terra firme*), to 1000 m, mostly below 600 m.

**Food and Feeding.** Little published. Feeds on variety of insects and arachnids; stomach contents of Surinam specimens included beetles (Coleoptera), hemipterans, homopterans, orthopterans (Acrididae), and false scorpions (Pseudoscorpionidae). Closely associated pair-members or individuals forage mostly 2-9 m above ground, occasionally to 15 m, obtaining food almost exclusively from recesses of curled, arboreal dead leaves; in 110 observations of foraging at a site near Manaus (Brazil), mean foraging height was 4.2 m and 98% of substrates were arboreal dead leaves. Almost always with mixed-species understorey flocks of *Thamnomanes* antshrikes, other antwrens, foliage-gleaners (Furnariidae) and other insectivores. In intraspecific displays, two or more males face each other less than 1 m apart, fluff the back feathers, flare out throat feathers, and pivot from side to side while vocalizing incessantly. Forages mostly along slender branches of understorey trees, on understorey palms, and in vine tangles; progresses rapidly by short hops, often hitching from side to side, ignoring intervening live foliage and systematically pausing to inspect arboreal dead leaves, both single hanging ones and clusters trapped in vines, branches and, especially, the tops of small palms. Gleans prey from smaller dead leaves mostly by reaching up with neck and legs extended, or by hanging head downwards from adjacent perches; from larger leaves (especially dead palm fronds) by hanging acrobatically like a tit (Paridae) from the margins (often upside-down) or bottom of the leaf itself, or by perching atop it; usually spends 5-15 seconds, but sometimes up to 1 minute or more, in rummaging audibly in a single leaf or cluster, and probing by delicately inserting the bill and sometimes the entire head into curls and crevices. Often works systematically along the rachis of dead palm fronds, leaning over to probe into each of the many curled blades; also inspects frayed and dying ends of mostly live fronds. When larger prey items are extracted, usually hops or flies to a nearby horizontal perch and bashes the captured arthropod forcefully against the branch, sometimes for up to a minute, until the prey is subdued. Protracted searches of individual leaves or clusters of leaves, combined with lengthy manipulating time for large prey items, mean that these birds are often left behind after more active flockmates have moved some distance on; in one study, foraging rates of this species were 12 moves per minute, significantly lower than those of three other *Myrmotherula* species that glean from live leaves (18.3-18.9).

**Breeding.** Not well known. Nests in French Guiana in Feb-Mar, Jun and Aug-Dec; in Brazil (near Manaus), nest found in May and young juvenile in Apr. Brazil nest was domed or oven-shaped, composed of leaves and twigs, irregular and untidy in appearance, situated 0.4 m up in bush inside *terra firme* forest; one in French Guiana described as a deep (15 cm) pouch with roof, laterally opened at top, composed externally of many dead leaves, herbs and fungal (*Marasmius*) fibres, internal cup 4.6 cm, attached to branch of small understorey tree and fern 1.5 m above ground, while another was at height of 1.4 m. Clutch 2 eggs, white, with light brown or violaceous spots forming conspicuous wreath at larger end; both sexes incubate, brood, and feed young during day; nestling period 11 days.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its range. The region occupied by this species contains a number of protected areas, examples of which are Imataca Forest Reserve and El Dorado, and Canaima National Park, in Venezuela, Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam, and Ducke Reserve and the various BDFPP INPA forests N of Manaus, in Brazil; also large contiguous expanses of intact habitat which, although not formally protected, are at little current risk of development. Wholesale logging and mining operations, along with human colonization and deforestation for subsistence agriculture, remain the primary long-term threats to this and other lowland-forest species of the Guianan region.

**Bibliography.** Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Dick *et al.* (1984), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Mason (1996), Meyer de Schauensee & Phelps (1978), Novas (1980), Oniki (1979c), Oniki & Willis (1982), Powell (1989), Reynaud (1988), Ridgely & Tudor (1994), Schönwetter & Meise (1988), Sick (1993), Snyder (1966), Stotz (1990b), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Thiollay (1988a, 1994), Tostain (2003), Tostain *et al.* (1992), Wiley (1980), Wilkinson & Smith (1997), Willis (1977, 1991), Zimmer (2003a).

## 76. Checker-throated Antwren

### *Myrmotherula fulviventr*

**French:** Myrmidon fauve

**Spanish:** Hormiguerito Leonado

**German:** Tropfenkehl-Ameisenschlüpfer

**Other common names:** Fulvous(-bellied) Antwren

**Taxonomy.** *Myrmotherula* [sic] *fulviventr* Lawrence, 1862, Lion Hill, Canal Zone, Panama.

Genetic, morphological and behavioural analyses indicate that this species is part of a monophyletic group that also includes *M. gutturalis*, *M. leucophthalma*, *M. spodiota*, *M. haematona*, *M. feldsaai*, *M. ornata* and *M. erythrura* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. Although four races have been described, namely, *costaricensis* (S Honduras to W Panama), *fulviventr* (E Panama to W Colombia), *salmoni* (C Colombia) and *viduata* (NW Ecuador), conflicting information surrounds the diagnosability and geographical ranges of these; further study required. Monotypic.

**Distribution.** Caribbean slope from extreme SE Honduras S to W Panama, thence both slopes E from Veraguas, and Colombia (Pacific slope, base of N end of Andes E to Santander, and Magdalena Valley S to Antioquia and Boyacá) and W Ecuador (S to E Oro).

**Descriptive notes.** 10-11 cm; 8.5-11.5 g. Male has grey-brown crown and upperparts, reddish remiges and tail; wing-coverts blackish-brown, more olive-brown in Magdalena Valley in Colombia ("salmon"), but apparently intergrading with other birds in N, coverts with large yellow-ochre tips; ear-coverts grey; throat black with large white spots; breast grey, rest of un-

derparts are mostly brownish-buff, darker posteriorly; iris golden, becoming rich chocolate-brown in older birds. Female differs from male in having side of head and throat brownish-buff. Juvenile has grey iris, becoming pale yellow in first-year plumage. **Voice.** Loudsong a variable series of abrupt, countable, almost staccato notes (e.g. 11 notes, 2-5 seconds), variable in pace, pitch and intensity, but often accelerates and intensifies initially and decelerates and dies off slightly at end; same note delivered much more rapidly in intraspecific agonistic display. Calls include a moderately long sibilant note and a rattle.

**Habitat.** Understorey of lowland and foothill evergreen forest and adjacent tall second-growth woodland; mostly below 1100 m, locally to 2000 m in Colombia. Favours, or perhaps requires, areas with abundant vine tangles supporting high density of aerial leaf litter.

**Food and Feeding.** Feeds on various insects, particularly cockroaches (Blattidae), crickets (Gryllidae) and katydids (Tettigoniidae), and spiders. Forages as closely associated pair-members, individuals, or family groups, 0.5-2.5 m above ground; in 126 observations in a study in Panama, mean height was 10.5 m; other fieldwork in Panama/Costa Rica suggests that most foraging is at 1-8 m. Food obtained almost exclusively from recesses of curled, arboreal dead leaves; in Panama study, 98% of its foraging time was spent in searching aerial leaf litter. Usually with mixed-species flocks of insectivores; studies on Barro Colorado I (Panama) indicate that territories are highly stable and typically coincide with those of *Microhousia quixensis*, or often of *M. axillaris*, which then travel in same flocks, and that the species co-defend their territories. In intraspecific displays, males face each other c. 30 cm apart, lower the head, fluff out back plumage, and pivot from side to side, vocalizing incessantly. Forages mostly in vine tangles and along slender branches of understorey trees, or on understorey palms; progresses rapidly by short hops, often hitching from side to side, ignoring intervening live foliage and systematically pausing to inspect single hanging dead leaves and also dead-leaf clusters trapped in vines, in branches and in tops of small palms. At higher elevations, also occasionally inspects leaf litter lodged in small epiphytes, and moss tangles along trunks of trees. Gleans prey from smaller dead leaves mostly by reaching up with neck and legs extended, or by hanging head downwards from adjacent perches; from larger leaves by hanging acrobatically like a tit (Paridae) from the margins (often upside-down) or bottom of the leaf itself, or by perching atop it; spends 5-15 seconds, and sometimes 1 minute or longer, in rummaging audibly in a single leaf or cluster, probing by delicately inserting the bill, sometimes the entire head, into curls and crevices. When larger prey item obtained, usually hops or flies to a nearby horizontal perch and bashes it forcefully against the branch, sometimes for up to a minute, until it is subdued. Owing to lengthy searching of leaves and protracted time spent in handling large prey, this species is often left behind after more active flockmates have moved on. Occasionally visits army-ant swarms for short periods, rarely sallying to ground or air to catch escaping insects.

**Breeding.** Mar-Aug in Costa Rica; in Panama, nests found in all months except Dec and Apr but concentrated in rainy season, and newly fledged young recorded on Barro Colorado I in Nov-Mar; a nest in Dec in Colombia. Nest a deep (15 cm), pensile pouch with oblique opening at top, composed of fine blackish-brown fungal filaments and rootlets, supporting thick layer of dead leaves, lined with fine fibres, c. 0.4-2 m (occasionally to 8 m) above ground in terminal fork of thin, drooping twig of understorey sapling, shrub or vine tangle; multiple nests often built by same pair. Normal clutch 2 eggs, white or cream-coloured, with reddish-brown, purplish-chestnut and pale lilac blotches, fine spots and scrawls mostly concentrated in wreath around larger end; incubation by both parents, only by female at night, period 18-20 days; juveniles in Panama continued to follow parents closely in mixed-species flocks, occasionally begging, for at least 4-6 months after fledging; courtship and nest-building commenced after young from previous year had dispersed. Of 26 and 51 nests in Panama in two successive years, success was 30.8% and 27.5%, respectively.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its range. This includes a number of protected areas, e.g. Braulio Carrillo National Park and La Selva Biological Reserve, in Costa Rica, Soberania and Darién National Parks and Comarca Kuna Yala Indigenous Reserve, in Panama, Los Katios National Park, in Colombia, and Río Palenque Science Centre and the Manglares-Churute Ecological Reserve, in Ecuador. Continued protection of the forests in these and other existing reserves should ensure the maintenance of viable populations of this species.

**Bibliography.** Blake & Loiseleur (2001), Carriker (1910), Cody (2000), Cory & Hellmayr (1924), Eisenmann (1952), Gradwohl & Greenberg (1980, 1982a, 1982b, 1984), Greenberg (1984), Greenberg & Gradwohl (1983, 1985, 1986, 1997), Hackett & Rosenberg (1990), Hilty (1997), Hilty & Brown (1986), Isler & Whitney (2002), Jones (1977), Levey (1988), Monroe (1968), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Robinson *et al.* (2000), Schemske & Brokaw (1981), Schönwetter & Meise (1967), Skutch (1969c), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Wiley (1971), Willis (1972b, 1980, 1984a), Willis & Eisenmann (1979), Zimmer (2003a).

## 77. White-eyed Antwren

### *Myrmotherula leucophthalma*

**French:** Myrmidon aux yeux blancs

**Spanish:** Hormiguero Ojiblanco

**German:** Olivbrauner Ameisenschlüpfer

**Taxonomy.** *Formicivora leucophthalma* Pelzel, 1868, Salto do Girão = Salto do Jirau, Rondônia, Brazil.

Genetic, morphological and behavioural analyses indicate that this species is part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. spodiota*, *M. haematona*, *M. fieldsai*, *M. ornata* and *M. erythrura* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. With exception of distinctive race *phaeona*, morphological distinctions among races are not clear, and ranges given below are tentative; further study needed. Four subspecies recognized.

**Subspecies and Distribution.**

*M. l. leucophthalma* (Pelzel, 1868) - E Peru (E of R Ucayali), W Brazil S of R Amazon (E to lower R Madeira and drainage of R Aripuanã) and NW & NE Bolivia (Pando, NE Santa Cruz).

*M. l. dissita* Bond, 1950 - SE Peru (Puno) and adjacent Bolivia (La Paz).

*M. l. phaeonota* Todd, 1927 - S Amazonian Brazil from lower R Madeira E to lower R Tapajós.

*M. l. sordida* Todd, 1927 - R Tapajós E to R Tocantins.

**Descriptive notes.** 9.5-11 cm; 8-10.5 g. Male nominate race has grey-brown crown and upperparts, reddish remiges and tail; wing-coverts blackish-brown with large cinnamon-tinged white tips; ear-coverts grey-brown; throat black, spotted white; breast and upper belly grey, posterior underparts grey with ochraceous tinge; iris pale, sometimes brown (probably age-related). Female differs from male in having throat cinnamon, side of head and underparts light olive-brown, centre of breast and upper belly variably tinged cinnamon. Race *sordida* male differs from nominate in having wing-covert tips white, female more cinnamon-tinged below; *dissita* male has wing-covert tips cinnamon, female with least cinnamon tinge below; *phaeona* has upperparts mainly reddish-brown in both sexes. **Voice.** Loudsong a moderately long series (e.g. 15 notes, 4 seconds) of

downslurred notes, first one usually drawn out, subsequent notes shortening as series speeds up and drops slightly in pitch, somewhat variable; in intraspecific agonistic display more complex, raspy notes, again often introduced by longer flatter note, with pace, length of series, etc. quite variable. Calls include abrupt downslurred notes, sometimes in doublets and triplets, or given in regularly paced series; also a rubbery rattle.

**Habitat.** Understorey of lowland evergreen forest (*terra firme*, transitional), to 700 m, rarely to 1050 m. Most common in forest with dense understorey and great abundance of ar-

boreal dead leaves, both hanging and trapped in vine tangles and understorey palms. Micro-habitat associations complex and geographically variable, possibly dependent on presence or absence of congeneric dead-leaf specialists. In Pando (Bolivia), restricted to streamside bamboo thickets and disturbed forest, and replaced in upland forest by *M. haematona*. In Mato Grosso (Brazil), occurs in upland and transitional forest, but usually absent from stands of bamboo, where replaced by *M. ornata*. Regularly occurs together with latter species in bamboo stands in E Peru (Madre de Dios). **Food and Feeding.** Feeds on insects and spiders; analysis of stomach contents of 18 specimens from Peru and Bolivia revealed that commonest prey were katydids (Tettigoniidae), crickets (Gryllidae) and cockroaches (Blattidae), followed by beetles (Coleoptera; virtually all less than 10 mm), spiders, heteropterans, and ants (Formicidae). Forages in pairs in close association, or individually, or in family groups, mostly 1-6 m above ground, occasionally to 15 m or higher, obtaining prey primarily from recesses of curled, arboreal dead leaves; in 89 observations at Cocha Cashu (Peru) mean foraging height was 2.78 m, and at two sites in Peru c. 90% and almost 99%, respectively, of food taken from dead leaves. Almost always with mixed-species understorey flocks of *Thamnomanes* antshrikes, other antwrens, foliage-gleaners (Furnariidae) and other insectivores. In intraspecific displays, males face each other c. 30 cm apart, lower the head, fluff out back plumage, and pivot from side to side, vocalizing constantly. In upland forest, forages mostly along slender branches of understorey trees and on understorey palms (e.g. *Geonoma*); in transitional forest, more often in vine tangles. Progresses rapidly by short hops, often hitching from side to side, ignoring intervening live foliage, and systematically pausing to inspect arboreal dead leaves, both individual hanging ones and clusters of dead leaves trapped in vines, branches and, especially, tops of small palms; in one study in Peru, medium-sized (10-15 cm) leaves used most often. Gleans prey from smaller dead leaves mostly by reaching up, with neck and legs extended, or by hanging head down from adjacent perches; from larger leaves (especially dead palm fronds) by hanging acrobatically like a tit (Paridae) from sides (often upside-down) or bottom of the leaf, or by perching atop it; usually spends 4-30 seconds (sometimes up to 1 minute or longer) in rummaging audibly in a single leaf or cluster, delicately inserting the bill and sometimes the entire head into curls and crevices. Also inspects frayed and dying ends of mostly live palm fronds. When larger item extracted, usually hops or flies to a nearby horizontal perch and bashes it forcefully against the branch, sometimes for up to a minute, until prey is subdued. Because of protracted searches of individual leaves or clusters, combined with prolonged time spent in handling large prey, is often left behind after more active flockmates have moved away some distance. Studies in Peru and observations in Brazil showed that, where this species occurs together with *M. ornata*, it forages lower, investigates larger leaves and specializes on palms, whereas *M. ornata* forages higher, investigating smaller leaves, and specializes on bamboo; evidence indicates that, in addition to responses to resource availability, species-specific foraging niches in this guild are influenced by co-occurring species.

**Breeding.** Almost nothing known. Nest-building reported from Peru (Cocha Cashu, in Madre de Dios) 15th-20th Oct.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its rather large range. Within this are several sizeable protected areas, such as Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi and Noel Kempff Mercado National Parks, in Bolivia, and Pacaás Novos and Tapajós National Parks, Cristalino State Park and Caxiuanã National Forest, in Brazil. In addition, its range contains vast contiguous areas of intact habitat which, despite being currently unprotected, remain at low risk of near-term development.

**Bibliography.** Alverson *et al.* (2000), Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Killean & Schulenberg (1998), Munn (1984, 1985), Munn & Terborgh (1979), Oren & Parker (1997), Parker (2003a), Parker & Bailey (1991), Parker & Remsen (1987), Remsen & Parker (1984), Ridgely & Tudor (1994), Rosenberg, K.V. (1990a, 1993, 1997, 2003), Servat (1996), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh *et al.* (1990), Valente (2000), Zimmer (2003a), Zimmer, Parker *et al.* (1997).

## 78. Foothill Antwren

### *Myrmotherula spodiota*

**French:** Myrmidon des contreforts

**Spanish:** Hormiguero Submontano

**German:** Westlicher Graubrust-Ameisenschlüpfer

**Other common names:** Ecuadorian Antwren

**Taxonomy.** *Myrmotherula spodiota* P. L. Sclater and Salvin, 1880, Sarayacu, Pastaza, Ecuador. Forms a superspecies with *M. haematona*, which formerly considered conspecific, and with *M. fieldsai*. Genetic, morphological and behavioural analyses indicate that all three are part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. leucophthalma*, *M. ornata* and *M. erythrura* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. Two subspecies recognized.

**Subspecies and Distribution.**

*M. s. spodiota* P. L. Sclater & Salvin, 1880 - E Andean slope from S Colombia (Cauca, Caquetá) S to N Peru (Amazonas N of R Marañón).

*M. s. sororia* Berlepsch & Stolzmann, 1894 - E slope in Peru S of R Marañón (San Martín S to Madre de Dios).

**Descriptive notes.** 10.5-11 cm; 9-10.5 g. Male has crown and upperparts dark grey, tinged brown, rump dark reddish yellow-brown; wing-coverts blackish-brown, greater coverts tipped pale buff, median and lesser coverts tipped white; flight-feathers and tail dark brown; throat black, spotted white; head side, breast and upper belly grey, lower belly, flanks and crissum reddish yellow-brown. Female is olive-brown above, rump tinged buff, wings and tail brown with wing-coverts dark brown, pinkish-buff wing-covert tips, yellow-ochre head side, throat and underparts, lower

**Food and Feeding.** Feeds on variety of insects, probably also spiders; in Ecuador, observed to take small cockroaches (Blattidae), lepidopteran larvae, adult moths, and a katydid (Tettigoniidae) more than 5 cm long. Closely associated pairs, individuals or family groups forage 0.5–8 m above ground (activities concentrated at 1–4 m), almost always with mixed-species flocks of insectivores. Forages almost exclusively at isolated dead leaves and dead-leaf clusters hanging or trapped above ground in understorey; also sometimes probes in tufts of moss and in shaggy, dead bark of understorey vines. Hitches rapidly along slender limbs of trees, frequently flicking the wings shallowly, and flicking the tail up or down sharply through an irregular arc, only rarely scanning live leaves, and pausing only to investigate suspended or trapped dead leaves. Probes smaller dead leaves by reaching from nearby perches; gleans from dead-leaf clusters and larger, isolated dead leaves by perching atop them or by hanging acrobatically, often after first shaking the leaf with its bill; spends anything from several seconds to 1 minute (rarely longer) in rummaging audibly in clusters and larger single leaves, inserting the bill into curls and crevices. When larger item extracted, usually hops or flies to a nearby horizontal perch and bashes it hard against branch, sometimes for up to a minute, until prey is subdued. Protracted time devoted to searching individual leaves or clusters, as well as to handling large prey, often causes this species to be left behind after the flock has moved well away.

**Breeding.** Almost nothing known. Family groups, and a food-begging juvenile with adults, recorded in late Mar in E Ecuador.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout its range. Although it occurs only in a narrow elevational belt, this does include some protected areas, e.g. Sumaco-Galeras and Sangay National Parks, in Ecuador. In general, the lower Andean slopes to which this species is restricted are some of the areas most at risk of deforestation and cultivation by an ever-expanding human population; even relatively common species living in this zone should, therefore, be considered worthy of monitoring.

**Bibliography.** Cory & Hellmayr (1924), Hilty & Brown (1986), Krabbe, Isler *et al.* (1999), Parker & Remsen (1987), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Salaman *et al.* (1999), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Whitney (1994a), Willis (1984a), Zimmer (1930, 1932a).

## 79. Stipple-throated Antwren

### *Myrmotherula haematonota*

French: Myrmidon cravaté

Spanish: Hormiguerito Dorsirrojo

German: Östlicher Graubrust-Ameisenschlüpfer

**Taxonomy.** *Formicivora haematonota* P. L. Slater, 1857, Chamicuros, Loreto, Peru.

Forms a superspecies with *M. spodionota*, which formerly considered conspecific, and with *M. fieldsaii*. Genetic, morphological and behavioural analyses indicate that they are all part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. leucophthalma*, *M. ornata* and *M. erythrura* (the “stipple-throated antwren assemblage”), and which may not be closely related to other species placed in the genus. Morphological distinctions between nominate race and *amazonica* possibly represent clinal variation, and geographical ranges considered tentative pending further study. Three subspecies recognized.

**Subspecies and Distribution.**

*M. h. pyrrhonota* P. L. Slater & Salvin, 1873 - SE Colombia (near base of Andes S from Meta, and E Vaupés), S Venezuela (Amazonas, Bolívar E to R Caroni drainage), extreme NE Ecuador (Sucumbios), NE Peru (Loreto N of R Napo and R Amazon) and NW Brazil (R Negro drainage and N Roraima).

*M. h. haematonota* (P. L. Slater, 1857) - E Peru S of R Napo and Amazon (Loreto S to Madre de Dios) and W Brazil (extreme SW Amazonas, Acre).

*M. h. amazonica* H. von Ihering, 1905 - SC Amazonian Brazil (both banks of R Jurua E to both banks of R Madeira and R Jiparaná) and N Bolivia (Pando).

**Descriptive notes.** 10.5–11 cm; 9–10 g. Male has crown to upper mantle greyish olive-brown, rest of upperparts, flight-feathers and tail deep rufous; wing-coverts blackish-brown, greater coverts tipped pale buff, median and lesser coverts tipped white; throat black, spotted white; head side, breast and upper belly light grey, lower belly, flanks and crissum yellow-brown. Female differs from male in having wing-covert tips more pinkish-buff, throat white to pale buff and variably streaked black, usually dark feather bases showing through, head side and underparts light yellowish olive-brown, darker on flanks and crissum. Race *pyrrhonota* male is very like nominate but rufous of upperparts perhaps brighter and clearer, female distinctive with head side and throat yellow-ochre, throat usually unstreaked (sometimes few fine streaks) and dark bases not apparent, breast and belly reddish yellow-brown to reddish-tinged buff, flanks and crissum olive-brown; *amazonica* is also similar, perhaps brighter above and paler below, female lighter rufous above, more ochraceous on throat, more greyish-brown on flanks and belly. **Voice.** Loudsong a trill of abrupt, sibilant notes first ascending and then gradually dropping in pitch, similar in pattern to that of *M. gutturalis* and *M. spodionota*, pace and length appear to vary regionally; in intraspecific agonistic display, song of complex and raspy notes, often introduced by up to 4–5 short clear notes. Calls include doublet of abrupt notes, second higher-pitched (recorded only for *pyrrhonota*); also abrupt single note, and high-pitched rattle.

underparts browner, throat with a few thin blackish streaks and dark feather bases giving mottled appearance. Race *sororia* barely differs from nominate, male more olive above, with rump, flanks and crissum less reddish, throat spots may average larger, female underparts paler. **Voice.** Loudsong a trill of abrupt, sibilant notes first ascending sharply and then gradually dropping in pitch, similar in pattern to that of *M. gutturalis*. Calls include short, high-pitched rattle.

**Habitat.** Understorey of foothill and montane evergreen forest, from 500 m (higher in some regions) to 1600 m.

## Family THAMNOPHILIDAE (TYPICAL ANTBRIDS) SPECIES ACCOUNTS

**Habitat.** Understorey of lowland evergreen forest (mostly *terra firme*), mostly below 500 m; to 1300 m in Venezuela and N Brazil (N Roraima). Replaces *M. leucophthalma* in upland forest in N Bolivia, where latter species locally restricted to streamside bamboo thickets and disturbed forest.

**Food and Feeding.** Feeds on insects and spiders. Analysis of stomach contents of 16 specimens from Bolivia revealed that commonest prey were orthopterans, i.e. katydids (Tettigoniidae) and crickets (Gryllidae), which accounted for more than 50% of all prey identified, and cockroaches (Blattidae), followed by spiders, beetles (Coleoptera; virtually all smaller than 10 mm), ants (Formicidae) and heteropterans; this species had the lowest dietary diversity of any of the 16 dead-leaf specialists studied. Closely associated pair-members, individuals, or family groups forage mostly 1–3 m above ground, also at 5–9 m in some regions; in one region of Bolivia, exhibited the most restricted height range of any of 16 species of dead-leaf specialists. Almost always with mixed-species understorey flocks of *Thamnomanes* antshrikes, other antwrens, foliage-gleaners (Furnariidae) and other insectivores. Food obtained almost exclusively from recesses of curled, arboreal dead leaves; in 81 observations of foraging in a study in Bolivia, dead leaves comprised 94% of foraging substrates. Forages mostly along slender branches of understorey trees and on understorey palms (e.g. *Geonoma*), less frequently in vine tangles; progresses rapidly by short hops, often hitching from side to side, ignoring live foliage and systematically pausing to inspect arboreal dead leaves, both single hanging ones and clusters trapped in vines, in branches and, especially, in tops of small palms; in Bolivian study, medium-sized (10–15 cm) leaves and palm leaves used most often. Gleans prey from smaller dead leaves mostly by reaching up, with neck and legs extended, or by hanging head first from adjacent perches; from larger leaves (e.g. *Cecropia*) by hanging acrobatically like a tit (Paridae) from sides (often upside-down) or bottom of leaf or by perching atop it, and from understorey palms by clinging to tips of leaflets; usually rummages audibly for 5–30 seconds (sometimes up to 1 minute or longer) in a single leaf or cluster, and probes by delicately inserting the bill, or sometimes the entire head, into curls and crevices. When larger arthropod extracted, usually hops or flies to a nearby horizontal perch and bashes prey against branch, sometimes for up to a minute, to subdue it. Because of time spent in searching individual leaves or clusters, combined with protracted handling time for large prey, this species is often left behind after more active flockmates have moved on some distance.

**Breeding.** Almost nothing known. Female with yolking egg in Mar in Venezuela (Cerro de la Neblina, in Amazonas).

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout most of its range. This includes some large protected areas, among them Yacapana, Duida and La Neblina National Parks and Caura Forest Reserve, in Venezuela, and Jaú and Serra do Divisor National Parks, in Brazil. Range also contains large, contiguous expanses of intact habitat which, although not formally protected, appear to be at minimal risk of development in the near term.

T. (1932a), Zimmer, K. J. (2003a).

## 80. Brown-backed Antwren

### *Myrmotherula fieldsaii*

French: Myrmidon de Fjeldsa

German: Braunrücken-Ameisenschlüpfer

Spanish: Hormiguerito del Yasuni

**Other common names:** Yasuni Antwren

**Taxonomy.** *Myrmotherula fieldsaii* Krabbe *et al.*, 1999, Río Tiputini, Napo, Ecuador.

Forms a superspecies with *M. spodionota* and *M. haematonota*. Genetic, morphological and behavioural analyses indicate that the three are part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. leucophthalma*, *M. ornata* and *M. erythrura* (the “stipple-throated antwren assemblage”), and which may not be closely related to other species placed in the genus. Monotypic.

**Distribution.** SE Ecuador (S & W of R Napo) and extreme NC Peru (N Loreto S to C R Tigre).

**Descriptive notes.** 10–11 cm; 9–10 g. Male has crown olive-brown, upperparts dark yellowish-brown, flight-feathers and tail darker with rufous tinge; wing-coverts blackish-brown, greater coverts tipped pale buff, median and lesser coverts tipped whitish; throat black, spotted white; head side, breast and upper belly light grey, lower belly, flanks and crissum pale yellowish-brown. Female differs in having head side ochraceous, chin and throat mostly white with dark streaks, underparts buffy brown. **Voice.** Loudsong a trill of abrupt, sibilant notes first ascending and then gradually dropping in pitch, similar in pattern to that of

*M. haematonota* (differences not yet established). Calls include ascending series of notes, also abrupt chips, and rattle.

**Habitat.** Understorey of evergreen forest (*terra firme*, transitional, to lesser extent *várzea*), at 150–300 m. May show preference for areas with abundance of palms in understorey.

**Food and Feeding.** Almost nothing published. Feeds on a variety of insects, particularly orthopterans (Gryllidae, Tettigoniidae) and coleopterans, probably also cockroaches (Blattidae); also on spiders. Food taken almost exclusively from recesses of curled, arboreal dead leaves. Closely associated pairs, individuals, or family groups forage mostly 1–8 m above ground, usually with mixed-species flocks of *Thamnomanes* antshrikes, other antwrens, foliage-gleaners (Furnariidae), Tawny-crowned Greenlets (*Hylophilus ochraceiceps*), Red-crowned Ant-tanagers (*Habia rubica*) and other insectivores. Often in same flocks as *M. erythrura*, then invariably foraging lower than that species. In upland forest, forages mostly along slender branches of understorey trees and on understorey palms (e.g. *Geonoma*); in transitional forest, more often in vine tangles. Progresses rapidly by short hops, often hitching from side to side, ignoring live foliage and systematically pausing to inspect arboreal dead leaves, both single hanging ones and clusters of dead leaves trapped in vines, branches and, especially tops of small palms. Gleans prey from smaller dead leaves mostly by reaching up, with neck and legs extended, or by hanging head first from adjacent perches; from larger leaves (especially dead palm fronds) by hanging acrobatically like a tit (Paridae) from sides (often upside-down) or bottom of leaf, or by perching atop it; usually spends several seconds

(sometimes up to 1 minute or more) in rummaging audibly in a leaf or leaf cluster, probing by delicately inserting the bill, even the entire head, into curls and crevices. Also inspects frayed and dying ends of mostly live palm fronds, and curled brown fronds of tree-ferns. Deals with larger prey items usually by hopping or flying to a nearby horizontal perch, where it bashes the arthropod forcefully against the branch, sometimes for up to a minute, until prey subdued. Long time spent in searches of individual leaves/clusters, combined with protracted handling time for large prey, means that this species is often left behind by more active flockmates.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and conservation.** Not globally threatened. Fairly common within the huge (7281 km<sup>2</sup>) Yasuni National Park, in Ecuador, much of which would appear to represent suitable habitat. Yasuni alone should allow for protection of a substantial population of this species, provided that intensified regional development through oil exploration and drilling is not allowed to compromise the ecological integrity of the park.

## 81. Ornate Antwren

*Myrmotherula ornata*

French: Myrmidon orné

German: Schmuckameisenschlüpfer

Spanish: Hormiguerito Ornado

Other common names: Chestnut-saddled Antwren; Black-throated Antwren (*atrogularis*)**Taxonomy.** *Formicivora ornata* P. L. Slater, 1853, "Bogotá" trade skin, Colombia.

Genetic, morphological and behavioural analyses indicate that this species is part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. leucophthalma*, *M. spodiota*, *M. haematonota*, *M. feldsaai* and *M. erythrura* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. Validity of races and ranges listed below uncertain; *saturata* possibly not diagnosably different from nominate, and it is unclear whether *meridionalis* and *atrogularis* intergrade; alternatively, *atrogularis* (with *meridionalis*) and also *hoffmannsi* may be shown to be two distinct species. Identity of rufous-backed birds near base of Andes in SC Peru (Cuzco) is uncertain. Further research required. Five subspecies recognized.

**Subspecies and Distribution.***M. o. ornata* (P. L. Slater, 1853) - C Colombia (Andean foothills in Meta).*M. o. saturata* (Chapman, 1923) - SC Colombia (E Nariño, E Cauca, Putumayo), E Ecuador and NE Peru (N of R Marañón, W of R Napo).*M. o. atrogularis* Taczanowski, 1874 - EC Peru (San Martín S to Ayacucho and Cuzco, E to Ucayali) and extreme SW Amazonian Brazil (extreme SW Amazonas, W Acre).*M. o. meridionalis* J. T. Zimmer, 1932 - SE Peru (Madre de Dios, Puno), adjacent Brazil (E Acre) and NW Bolivia (Pando, La Paz, Cochabamba).*M. o. hoffmannsi* Hellmayr, 1906 - SE Amazonian Brazil E of R Madeira (in E Rondônia, W & N Mato Grosso, and Pará W of R Tocantins).

**Descriptive notes.** 9-10 cm; 8.5-11 g. Male nominate race is grey above, back and rump rufous-chestnut; remiges and tail blackish-grey, wing-coverts tipped white, tail thinly edged white; throat black; underparts pale grey, flanks and crissum tinged brown. Female has grey of crown and upperparts replaced by greyish olive-brown, black throat streaked white, head side and underparts olive-tinged cinnamon, darkest on flanks and crissum. Race *saturata* is very like nominate, perhaps darker, more deeply coloured, female slightly darker; *hoffmannsi* male is paler below, tinged yellowish-brown posteriorly, female lacks throat

patch, is buff with cinnamon-rufous tinge below and tinged olive posteriorly; *meridionalis* lacks rufous-chestnut on upperparts, male pale grey below, female intermediate between grey and greyish olive-brown above, buff with cinnamon-rufous tinge below; *atrogularis* resembles previous, but female greyer above, no cinnamon tinge below. **VOICE.** Loudsong a short (e.g. 1-1.5 seconds) high-pitched trill starting with emphatic note, descending slightly in pitch and often in intensity; in intraspecific agonistic display, song consists of a countable series of raspy notes usually descending in pitch, length variable. Common call a sharp, high-pitched "seet".

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest (*terra firme*, transitional, *várzea*, *ligapó*), to 1400 m. Widely distributed in forest where no closely related congeners present. In areas inhabited also by close relatives, is generally (not always) restricted to particular habitats, such as extensive stands of bamboo (*Guadua*) within forest, or forest-edge and light-gap vine tangles away from bamboo, or riverine habitats, including second growth. Whether habitat differences are consistent with genetic differences remains to be investigated. Regularly occurs together with *M. leucophthalma* in bamboo stands in E Peru (Madre de Dios), but replaces that species in bamboo in upland and transitional forest in Mato Grosso (Brazil).

**Food and Feeding.** Feeds on a variety of insects and spiders; analysis of stomach contents of seven specimens from Peru revealed that commonest prey were orthopterans, i.e. katydids (Tettigoniidae) and crickets (Gryllidae), followed in order by spiders, coleopterans (virtually all less than 10 mm), heteropterans, cockroaches (Blattidae), and larvae. In an experiment using birds in outdoor cages, this species rejected harvestmen (Opiliones), but readily captured and consumed butterflies (Lepidoptera) and dragonflies (Odonata); it would not eat small lizards or frogs. Food taken almost exclusively from recesses of curled, arboreal dead leaves; in 538 observations of foraging in a study in Peru (Madre de Dios), dead leaves comprised 98% of foraging substrates. Closely associated pairs, individuals, or family groups forage mostly 4-9 m above ground, less frequently at 1-3 m and up to 20 m; in some regions usually with mixed-species flocks of other insectivores, but in others joins mixed flocks only as they move through its more restricted territory. In intraspecific displays, males face each other c. 30 cm apart, with wings half-opened and tail fanned, and raise and lower the head and tail while vocalizing incessantly. Where associated with bamboo thickets, forages mostly in crowns of those plants; in other areas mostly in dense mid-storey vine tangles. Progresses rapidly by short hops, often hitching from side to side and flicking its wings, mostly ignoring live foliage (although occasionally scans and opportunistically gleans from live leaves), and systematically pausing to inspect arboreal hanging dead leaves and clusters of dead leaves trapped in vines and branches; in one study in S Peru, medium-sized (10-15 cm) leaves and bamboo leaves were used most often. Gleans prey from smaller dead leaves mostly by reaching up, with neck and legs extended, from adjacent perches (typically vines or bamboo stems), or by hanging head first with the tail fanned and used as a brace against perch; from larger leaves less frequently by hanging acrobatically like a tit (Paridae) from sides (often upside-down) or bottom of the leaf or by perching atop it; rummages audibly for usually 2-10 seconds (sometimes up to 1 minute) in a single leaf or cluster, probing by delicately inserting the bill, sometimes the entire head, into curls and crevices. Seems to spend less time in probing each leaf than do other *Myrmotherula* dead-leaf specialists, and also more likely to glean dead leaves from adjacent perches, rather than while hanging from or sitting on the leaf itself; this especially true of individuals in bamboo thickets, as most dead bamboo leaves are small enough to be quickly scanned and are not big enough to make good perches. When larger arthropods extracted, usually hops or flies to a nearby horizontal perch and bashes the prey forcefully against branch, sometimes for up to a minute, until it is subdued. Studies in Peru and observations in Brazil showed that, where this species and *M. leucophthalma* occur together, they differ significantly in foraging behaviour, present species

using higher foraging height, investigating smaller leaves and, in some regions, specializing on bamboo (instead of palms); evidence suggests that, in addition to responses to resource availability, species-specific foraging niches in this guild are influenced by co-occurring species, but behavioural studies are needed in further localities.

**Breeding.** Little known. Dec-Jul in lowland Ecuador; young fledglings seen in Jul in SE Peru.**Movements.** None recorded; presumed resident throughout range.**Status and Conservation.** Not globally threatened. Fairly common, but locally distributed throughout. Its large range includes several large protected areas, e.g. Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Serra do Divisor and Tapajós National Parks and Cristalino State Park, in Brazil, and Madidi National Park, in Bolivia. In addition, vast contiguous areas of intact habitat within the regions occupied by this species appear to be at little near-term risk of development, although they are not formally protected.

**Bibliography.** Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Kratter (1997a), Munn (1985), Oren & Parker (1997), Parker (2003a), Pearson (1977a), Remsen & Parker (1984), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Rosenberg (1993, 1997, 2003), Servat (1996), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Wiley (1980), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

## 82. Rufous-tailed Antwren

*Myrmotherula erythrura*

French: Myrmidon à queue rousse

Spanish: Hormiguerito Colirrufo

German: Rostschwanz-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula erythrura* P. L. Slater, 1890, Rio Napo, Ecuador.

Genetic, morphological and behavioural analyses indicate that this species is part of a monophyletic group that also includes *M. gutturalis*, *M. fulviventris*, *M. leucophthalma*, *M. spodiota*, *M. haematonota*, *M. feldsaai* and *M. ornata* (the "stipple-throated antwren assemblage"), and which may not be closely related to other species placed in the genus. Races possibly intergrade. Two subspecies recognized.

**Subspecies and Distribution.***M. e. erythrura* P. L. Slater, 1890 - extreme NW Brazil (W bank of upper R Negro), SE Colombia (Meta E to Vaupés and S to Putumayo), E Ecuador and NE Peru (N of R Marañón and R Amazon).*M. e. septentrionalis* J. T. Zimmer, 1932 - E Peru (along base of Andes S of R Marañón S to Puno) and WC Amazonian Brazil (scattered records from Amazonas S of R Solimões, E to Tefé and middle R Juruá).

**Descriptive notes.** 10-11 cm; 9.5-12.5 g. Male has forehead to mantle olive-brown, back and tail rufous-chestnut; remiges brown, wing-coverts mostly blackish-brown, tipped pale buff or white; throat whitish, irregularly streaked black; neck side and breast grey, lower underparts light olive-brown to buff-brown. Female is similar to male, except side of head tinged buff, throat and breast ochre, lower underparts tinged ochre. Race *septentrionalis* female has side of head and underparts more ochraceous. **VOICE.** Loudsong apparently a countable, more or less evenly paced series of high-pitched "wheet" notes (e.g. 9 notes, 3-5 seconds) of

variable shape, but mostly upslurred, duration changes with each song (usually 5-12 notes); a more rapid trill, similar to that of *M. haematonota*, has also been attributed to this species; in intraspecific agonistic display, song consists of a countable series of raspy notes, length variable. Call a short, high pitched, upslurred note, also a rattle.

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest, primarily *terra firme*, but also transitional and *várzea*; mostly below 600 m, locally to 900 m.

**Food and Feeding.** Little published. Feeds on insects and spiders, taken almost exclusively from recesses of curled, arboreal dead leaves. Closely associated pair-members, individuals, or family groups forage mostly 5-15 m above ground, also at times near ground, usually with mixed-species flocks of other insectivores, including *Thamnomanes* antshrikes, woodcreepers (Dendrocolaptidae), foliage-gleaners (Furnariidae) and other antwrens. In intraspecific display, males face each other c. 30 cm apart, fluff out back plumage, spread wings and tail, and pivot from side to side, vocalizing constantly. Forages actively, but deliberately, often in vine tangles in interior of larger trees, or in crowns of understorey trees, hitching along vines and slender branches in zigzag progression; ignores live foliage, but systematically pauses to scan suspended single dead leaves, as well as dead-leaf clusters. Gleans prey from dead leaves by reaching up, out or down from nearby perches; often hangs head first to probe curled leaves with its bill, and frequently hangs acrobatically from undersides or margins of larger dead leaves. Commonly spends 10 seconds or more in probing a single leaf or cluster, often audibly rustling the leaf but not tearing it apart.

**Breeding.** Little known. Nest-building in Feb in Ecuador. Nest in Peru (season not recorded) described as dome-shaped with side entrance, compactly constructed from dried leaves, built in dense branches in bush or inside hanging palm frond; pair in Ecuador carrying nesting material to tangle of dead leaves and vines 2 m above ground, next to stream.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Not well known; considered fairly common throughout most of its range. Regions inhabited by this species contain several protected areas (e.g. Yasuni National Park, in Ecuador, and Manu National Park and Biosphere Reserve and Pacaya-Samiria National Reserve, in Peru) with substantial amounts of suitable habitat; they also encompass extensive contiguous areas of intact habitat which, although not formally protected, appear to be at little risk of development in the near future.

**Bibliography.** Alvarez (1994), Alverson *et al.* (2001), Arvin (2003), Cory & Hellmayr (1924), English (1998), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler & Whitney (2002), Koepcke (1972), Pearson (1977a), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Stotz *et al.* (1996), Tallman & Tallman (1994), Wiley (1980), Willis (1984a), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a).

## 83. White-flanked Antwren

*Myrmotherula axillaris*

French: Myrmidon à flanes blancs

Spanish: Hormiguerito Flanquialbo

German: Weißflanken-Ameisenschlüpfer

Other common names: Black Antwren

**Taxonomy.** *Myrmotherula axillaris* Vieillot, 1817, Guiana = French Guiana.

According to genetic studies, may be most closely related to *M. longipennis* and *M. menetriesii*. Also, *M. fluminensis* thought by some to be possibly a variant of race *luctuosa* of present species or, earlier, a hybrid between it and *M. unicolor*. Often grouped with those four species and *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. behni*, *M. grisea*, *M. snowi* and *M. urosticta* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Substantial geographical differences in vocalizations strongly suggest that present species should be split into several distinct species, but further work required. Otherwise, morphological distinctions between races *heterozyga* and *fresnayana* unclear. Distributions of races given below are tentative, based primarily on previous published statements. Six subspecies recognized.

**Subspecies and Distribution.**

*M. a. albifluga* Lawrence, 1865 - Caribbean slope from SE Honduras S to Colombia (except Santa Marta Mts), and Pacific slope from C Panama (Panamá, Darién) S to Ecuador.

*M. a. melaena* (P. L. Sclater, 1857) - Santa Marta Mts and Colombia E of Andes, W Venezuela (Andean slopes E to Mérida and Barinas and, S of R Orinoco, E to R Caura), NW Brazil (upper R Negro S to N bank of R Amazon), E Ecuador and NE Peru (Amazonas, San Martín, Loreto).

*M. a. axillaris* (Vieillot, 1817) - E Venezuela (Apure, Monagas, Delta Amacuro, and S of R Orinoco E of R Caura), Trinidad, the Guianas, E Amazonian Brazil (from both banks of lower R Negro E to Amapá and, S of R Amazon, E of R Madeira to Maranhão and S to NE Mato Grosso and Tocantins) and NE Bolivia (NE Santa Cruz).

*M. a. heterozyga* J. T. Zimmer, 1932 - EC Peru (Ucayali S to Madre de Dios) and SW Amazonian Brazil (W of R Madeira).

*M. a. fresnayana* (d'Orbigny, 1835) - extreme SE Peru (Puno) and NW Bolivia (W of R Mamoré, and along base of Andes E to W Santa Cruz).

*M. a. luctuosa* Pelzel, 1868 - coastal E Brazil (Paraíba S to Rio de Janeiro).

**Descriptive notes.** 9-10 cm; 7-9 g. Male nominate race is dark grey, concealed white interscapular patch; wings and tail blackish, remiges edged grey, wing-coverts and tail tipped white; throat, breast and centre of belly black, flanks white, crissum grey with subapical black spots and pale grey tips. Female is olive-brown above, shading to reddish yellow-brown on rump, with wings and tail dark brown, edged light cinnamon-rufous, wing-coverts edged cinnamon, side of head mottled pale olive-brown, throat and flanks white, rest of underparts rich buff, becoming olive-brown on sides, reddish-brown on

crissum. Juvenile male is like female, except wings and anterior upperparts mixed yellow-brown and grey, underparts mixed white and grey, tail like adult male; subadult male lacks black on throat and breast, has wings and coverts edged and spotted pale yellow-brown. Race *albifluga* is blacker (variable), scapulars strongly edged white, female is greyer above with wing-coverts tipped pale buff, paler below, crissum buff; *melaena* male resembles previous, female is similar to nominate but paler; *heterozyga* and *fresnayana* males are slightly paler, black of underparts more confined, females paler and less rufescent throughout (E populations typically most pale, but variable), tips of rectrices buff; *luctuosa* male is somewhat paler, flanks mostly pale grey (rather than white), white tail tips larger, female with head ashy grey, upperparts olive-tinged grey, wing-covert tips buff, rather faint, underparts ochraceous. Voice. Loudsong of nominate race, *heterozyga* and *fresnayana* a rapid uncountable series of abrupt notes, somewhat low-pitched (e.g. 3-2.2 kHz) compared with congeners, dropping sharply in pitch and gaining in intensity at beginning, then more or less levelling, pace varies geographically (slowest in SE Amazonia); of *albifluga* and *melaena* a countable, evenly paced series of whistles (e.g. 9 notes, 2-8 seconds), dropping in pitch, but gaining and then dropping in intensity; of *luctuosa* begins and ends with short harsh (frequency modulated) notes, middle ones become longer and clearer, pace slows then speeds up, intensity increases then decreases, pitch is flat and notes countable (e.g. 13 notes, 2-9 seconds). Common call (most races) typically of two notes, first shorter and higher-pitched, sometimes extended to 3-4 notes, other calls include sharp upslurred "weep", sometimes doubled or tripled, also very short "pip", much longer "chirr", and a rattle (possibly not all calls delivered by all races); *luctuosa* call a short, mostly downslurred note, singly or sometimes repeated, also calls similar to those of other races.

**Habitat.** Understorey and mid-storey of evergreen forest (*terra firme*, transitional, and *várzea* *igapó*) and second-growth woodland, to 1200 m. In most parts of range, not obviously confined to any particular micro-habitat type within forest. In some regions, however, appears to be highly restricted to one micro-habitat type, such specialization sometimes varying geographically among populations currently considered as belonging to same taxon. In Brazil, nominate race appears largely restricted to stands of *Guadua* bamboo within forest in N Mato Grosso, but virtually confined to river-edge forest without bamboo in other locations in S Amazonia (SW Pará, SE Amazonas, NE Rondônia) and in parts of Amapá; conversely, populations of same taxon in E Venezuela and much of N Brazil show no such specialization. In Nicaragua, *albifluga* seems to require light-gaps in its territory.

**Food and Feeding.** Feeds mostly on insects and spiders. Stomach contents of specimens included following: from Surinam, spiders, dipterans (Tipulidae), lepidopteran larvae; from Amazonian Brazil, cockroaches (Blattidae), true bugs (Hemiptera), beetles (Coleoptera); and from Peru/Bolivia (21 specimens), in decreasing order of proportion, orthopterans, beetles, spiders, true bugs (Heteroptera), larvae, cockroaches (Blattidae), ants (Formicidae), dipterans. Also catches adult lepidopterans (moths), but clips and removes the wings before consuming body. In extensive study in Peru/Bolivia, orthopterans, beetles and larvae were selected more than expected, and many fewer ants, flies and wasps (Hymenoptera) were taken than would be predicted, on basis solely of their respective availability; in same prey-selection experiment, but using birds in outdoor cages, nearly all ants, flies and wasps and most beetles and heteropterans were ignored or rejected, but the birds readily consumed cockroaches, spiders, crickets (Gryllidae), katydids (Tettigoniidae), some grasshoppers (Acrididae), butterflies (Lepidoptera) and dragonflies (Odonata), as well as a 5-cm lizard, which was captured, beaten on branch, and swallowed whole. In most regions, forages in pairs, singly or in family groups, mostly 2-12 m above ground in relatively open area between lower dense mid-storey and upper parts of dense understorey. Mean foraging height in 181 observations

at Cocha Cashu (Peru) was 5-4 m, and in 150 observations in Manaus (Brazil) 7-1 m; forages lower in regions of restricted habitat usage, e.g. elsewhere in Brazil means of 3-8 m in Espírito Santo (573 observations) and 3-1 m in Rondônia (206 observations). Very active, constantly hopping and changing direction, scanning foliage between movements but seldom pausing for more than 2 seconds, and always flicking the wings to reveal white flank patches. Obtains prey primarily from upper and lower surfaces of live leaves (mostly), stems and vines by perch-gleans; also with acrobatic hangs from branchlets or leaf petioles, short lunging stabs, and short sallies (these often fluttering upwards to underside of overhanging vegetation). In E Brazil (*luctuosa*) about a quarter of all foraging manoeuvres aimed at dead-leaf clusters; rather than probing these as do congeneric dead-leaf specialists, it strikes them with the bill to dislodge insects. Inspects suspended dead leaves also in Amazonia, but less frequently. Travels alone in some regions, but in most occurs typically with mixed-species flocks, exact composition of which varies greatly over extensive range. Where a core member of understorey flocks, it shares a common territory with other thamnophilids in the flock but appears not to be a flock-leader. Where occurring in same mixed-species flocks as *M. longipennis*, tends to spend much more time in the viny tangles along trunks and in leafier, more densely foliated portions of understorey trees; also sallies or hover-gleans much less than that species. At a study site in Nicaragua (*albifluga*), tended not to occur in same mixed flocks as *Microhousia quixensis*, but unclear whether this reflected interspecific competition or micro-habitat preferences. Occasional records from Panama, Colombia, Trinidad, Guyana, Surinam and Brazil of attending army ants (mostly *Eciton burchelli*, in Panama occasionally also *Labidus praedator*), although most visits less than 5 minutes in duration; other than a tendency to descend lower, little evidence that it modifies its foraging behaviour in presence of ants.

**Breeding.** Mar-Jul in Costa Rica, Mar-Aug in Panama, Jul-Dec and Feb-Mar in French Guiana, Feb-Oct in E Ecuador, Sept-Nov in E Peru; Jun-Dec in N Brazil, and juveniles fed by adults in Sept in SC (Mato Grosso); one record of adult feeding fledglings just out of nest in Sept in Surinam. Additional nest and egg descriptions from Brazil, Peru, Trinidad, Venezuela. Nest a deep cup composed largely of dead leaves and leaf skeletons (including leaves of bamboo and palms), often with asymmetrically placed dead leaves hanging from bottom, lined, held together and attached at rim with black fungal rhizomorphs, suspended from horizontal fork between twigs, usually with overhanging leaf or leaves, 0.2-4 m above ground in understorey sapling or shrub. Normal clutch 2 eggs, white or pinkish-white, with reddish-brown, deep purple and/or lilac gray speckles, scrawls and blotches concentrated in wreath at larger end; incubation by both parents during day, only female at night, period in Panama 16-19 days; at two nests in Panama, parents incubated for only 76% and 50%, respectively, of time during which observed, suggesting lower levels of nest attendance than in many other thamnophilids; brooding and feeding of nestlings shared by both parents, nestling period in Panama 8-12 days. Nesting success in one year at site in Panama was 22-2% for 18 nests.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout its large range. Regions in which it occurs contain numerous protected areas, as well as vast contiguous areas of intact, suitable habitat that are not formally protected. Furthermore, this species has been shown to survive in secondary forest and smaller forest isolates, and is seemingly more tolerant of disturbance than are congeners. The isolated E Brazilian race *luctuosa* is of more concern, given its relatively small range and the overall regional level of deforestation; at present, it remains fairly common in several protected areas, including Sooretama Biological Reserve, Linhares Natural Reserve, Monte Pascoal National Park, Porto Seguro/Florestas Rio Doce SA Forest, and Murici Ecological Reserve.

## 84. Slaty Antwren

*Myrmotherula schisticolor*

French: Myrmidon ardoisé

Spanish: Hormiguerito Pizarroso

German: Hochland-Ameisenschlüpfer

**Taxonomy.** *Formicivora schisticolor* Lawrence, 1865, Turrialba, Cartago, Costa Rica.

Close relationship to *M. sunensis* and *M. minor* suggested by similarities in morphology, behaviour and vocalizations. Often grouped with those and *M. axillaris*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Three subspecies recognized.

**Subspecies and Distribution.**

*M. s. schisticolor* (Lawrence, 1865) - Extreme SE Mexico (Chiapas) S on lower mountain slopes (Caribbean slope N of Nicaragua, mostly Pacific slope in Panama) to Colombia (W & WC Andes) and Ecuador (Pacific slope).

*M. s. sanctaemartae* J. A. Allen, 1900 - NE Colombia (Santa Marta Mts and Perijá Mts) and N Venezuela (Perijá Mts, Andes and coastal range E to Sucre).

*M. s. interior* (Chapman, 1914) - Andes in Colombia (W slope of C range, E range, E slope of S range) and on E slope S to Peru (S to Puno).

**Descriptive notes.** 9-10 cm; 8.5-10 g. Male nominate race is dark grey, wings darker, throat and upper breast black; concealed white interscapular patch; wing-coverts and crissum feathers with black subapical spot and whitish tip; tail thinly edged white in fresh plumage. Female is greyish-olive above, flight-feathers and tail browner, wing-coverts edged rufous, throat pale cinnamon, centre of underparts cinnamon with tawny tinge, mixed with olive-brown on sides and flanks, lower underparts yellowish-brown. Subadult male is like female, but black throat feathers starting to appear. Race *sanctaemartae* male is substantially paler than nominate, black restricted to throat and centre of uppermost breast, wing edgings browner, female much greyer on upperparts, underparts more extensively yellow-brown; *interior* male is intermediate, white interscapular patch minimal, female is more blue-grey and darker above than previous, more extensively cinnamon, tinged

tawny, below. VOICE. Loudsong consists of upslurred whistle sounding like "wheet", repeated singly at intervals of 1.5-2 seconds, or in groups of 2-4 at shorter intervals (e.g. 0.9-1.2 seconds) with longer spaces between groups. Calls include downslurred nasal whine, given singly, also same type of note turned into nasal "chirr" by overtones; also sharp "chip" notes, sometimes strung together into twitter. **Habitat.** Understorey of montane and foothill evergreen forest and adjacent second-growth woodland, mostly at 600-1700 m; locally to 2400 m or down to near sea-level. Primarily in wet, mossy cloudforest in most

of range, and generally at higher elevations than most congeners, but locally in semi-humid forest down to lowlands of Pacific slope in Costa Rica, Panama and Ecuador, and on Caribbean slope in Venezuela.

**Food and Feeding.** Little published. Feeds on various insects and spiders; stomach contents of single Panama specimen included homopterans (Fulgoroidea) and many spiders. Forages in pairs, individually or in family groups, 0-12 m above ground (mostly 1-6 m); sometimes alone, but more often with mixed-species flocks of other insectivores. Very active, constantly hopping and changing direction, scanning foliage between movements, but seldom pausing for more than 2 seconds, and always flicking the wings. Gleans prey from upper and lower surfaces of live leaves (mostly), stems and vines, using reaches, acrobatic hanging from branchlets or leaf petioles, short lunging stabs, also short sallies (these often fluttering hover-gleans upwards to underside of overhanging vegetation). Often jumps up and strikes undersides of large leaves with enough force to move them visibly, sometimes clinging acrobatically beneath a leaf for fraction of a second before abruptly fluttering down a metre or so to a lower perch, or even to the ground in pursuit of dislodged prey; sudden "flutter-downs" are a common feature of the foraging repertoire. Sometimes drops briefly to ground to take prey from surface of leaf litter. Regularly inspects suspended dead leaves and dead-leaf clusters, sometimes lingering for up to 20 seconds at a leaf; unlike true dead-leaf specialists, does not skip from one leaf to the next while ignoring intervening live vegetation, but opportunistically scans dead leaves in the course of its foraging; inspects dead leaves either by clinging acrobatically to the margins or underside or by reaching or hanging from an adjacent perch. Once observed persistently following a swarm of army ants (*Neivamyrmex*) at c. 1700 m in Colombia; also, one record of ant-following in Costa Rica.

**Breeding.** Mar-Jul in Costa Rica; adults feeding begging juveniles in Jan-Feb in Venezuela. Nest a deep cup of black fungal rhizomorphs, thinly woven (contents often visible through the fabric), bound by cobwebs, suspended by rim from horizontal fork or two diverging or nearly parallel branches of sapling 0.9-2 m above ground. Normal clutch 2 eggs, white or cream, blotched, speckled or scrawled with reddish or purplish-brown throughout, or markings concentrated in wreath around larger end; incubation by both parents during day, male taking greater share, only by female at night, period at one nest c. 15 days; chick hatches without down, and with yellow lining of mouth; brooding and feeding of chicks by both parents, nestling period c. 9 days.

**Movements.** None recorded, presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common over most of its rather large range. A number of protected areas exist within regions inhabited by this species, e.g.: Carara Biological Reserve, Monteverde Forest Reserve, La Amistad International Park and Braulio Carrillo National Park, in Costa Rica; Volcán Barú National Park and Fortuna Forest Reserve, in Panama; Henri Pittier, Guatopo and Yacambú National Parks, in Venezuela; Sumaco-Galeras and Machalilla National Parks, in Ecuador; and Manu National Park and Biosphere Reserve, in Peru. The foothill and middle-elevation slopes favoured by this species are often subject to the most intensive pressure from human colonization and cultivation, which could place some of its populations at risk.

**Bibliography.** Alverson *et al.* (2001), Behrstock (2003), Cory & Hellmayr (1924), Gochfeld & Tudor (1978), Hackett & Rosenberg (1990), Hilty (1997, 2003a), Hilty & Brown (1986), Howell & Webb (1995a), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Miller (1963), Monroe (1968), Parker & Carr (1992), Powell (1979), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Schönwetter & Meise (1967), Schulenberg & Awbrey (1997a), Skutch (1969c), Slud (1964), Stiles & Skutch (1989), Stotz *et al.* (1996), Tallman & Tallman (1994), Vallyely (2001), Wetmore (1972), Whitney (1994a), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a).

## 85. Rio Suno Antwren

### *Myrmotherula sunensis*

**French:** Myrmidon du Suno

**Spanish:** Hormiguerito del Suno

**German:** Kleiner Silberameisenschlüpfer

**Other common names:** Suno Antwren

**Taxonomy.** *Myrmotherula sunensis* Chapman, 1925, Rio Suno, Napo, Ecuador.

Close relationship to *M. schisticolor* and *M. minor* suggested by similarities in morphology, behaviour and vocalizations. Often grouped with those and *M. axillaris*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Two subspecies recognized.

**Subspecies and Distribution.**

*M. s. sunensis* Chapman, 1925 - SC Colombia (E slope of Andes in Meta and Putumayo) and Ecuador (Sucumbios, Napo, Pastaza); specimen from "mouth of R Curaray" (Peru) may have originated from Ecuador.

*M. s. yessupi* Bond, 1950 - EC Peru (Huánuco, Pasco); also SW Amazonian Brazil (R Juruá but precise location uncertain, probably also R Javari).

**Descriptive notes.** 9 cm. Tail short. Male is grey, wings darker, throat and centre of upper breast black; concealed white interscapular patch, wing-coverts tipped white; underwing-coverts grey. Female is olive-brown above, browner on wings and tail, underparts dull buff, tinged rufous, sides, flanks and crissum tinged olive-brown. Subadult male is like female, but underparts greyer, throat and upper breast may start to show black. Race *yessupi* female is greyer above, less rufescent below. VOICE. Loudsong a series of 2-5 similar, evenly paced, somewhat long thin whistles (e.g. 4 notes, 1-5 seconds) at moderate pitch (c. 5 kHz), first note often slightly higher, intervals between notes shorter than notes. Call a thin, upslurred "wheet", slightly lower-pitched than loudsong, often in pairs.

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest and adjacent older second-growth woodland; to 900 m, mostly at 200-500 m. Primarily, if not entirely, in *terra firme*

forest in Ecuador; recent records from E bank of R Javari (Brazil) were from *várzea*/transitional forest. Exact micro-habitat requirements not well understood, but seems to prefer areas in which understorey is dense and viny, with abundant *Heliconia*, and with abundance of suspended aerial leaf litter within 5 m of ground.

**Food and Feeding.** Not well known. Feeds on insects, probably also spiders. Forages in pairs, individually or in family groups, 1-7 m above ground (mostly 2.5-5 m), usually with mixed-species flocks of other insectivores, including (locally) up to 7 species of congener. Compared

with congeners, forages lethargically; hops and hitches along horizontal and inclined limbs, branches and twigs, gleans and reaches deliberately without hanging, sallying, fluttering or other acrobatic moves; sometimes clings momentarily to vertical stems and vines, and flicks wings and tail irregularly (somewhat less often than many congeners). Gleans from both live foliage and isolated, often small, dead leaves by stretching the legs, craning the neck and reaching for prey; not observed to hop directly on to dead leaves, and seldom pokes or probes them. Inspects dead-leaf clusters from the periphery, but does not rummage in these. Of 40 observed foraging manoeuvres in one study, majority were to dead leaves, but the birds did not manipulate the leaves with the bill or feet; species thus classed as a regular, non-specialist user of dead leaves.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Apparently patchily distributed and uncommon to rare throughout its range. Known to occur in a few large, protected areas, e.g. Yasuni and Sumaco-Galeras National Parks, in Ecuador, but more survey work is needed in order to permit a better assessment of the true distributional limits and status of this species.

**Bibliography.** Cadena, Álvarez *et al.* (2000), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler & Whitney (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Stotz (1990c), Stotz *et al.* (1996), Tallman & Tallman (1994), Whitney (1994a, 2003a), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a).

## 86. Salvadori's Antwren

### *Myrmotherula minor*

**French:** Myrmidon de Salvadori

**Spanish:** Hormiguerito de Salvadori

**German:** Salvadoriameisenschlüpfer

**Taxonomy.** *Myrmotherula minor* Salvadori, 1864, Brazil.

Close relationship to *M. schisticolor* and *M. sunensis* suggested by similarities in morphology, behaviour and vocalizations. Often grouped with those and *M. axillaris*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Specimens from SW Amazonia tentatively assigned to this species by earlier authors, but identity of these requires substantiation, including further field studies and vocal and molecular analysis; may represent a distinct species. Monotypic.

**Distribution.** Coastal SE Brazil from SE Bahia S to extreme NE Santa Catarina; also old records from E Minas Gerais.

**Descriptive notes.** 9 cm; one female 6.4 g. Tail short. Male is grey, paler below, throat and centre of upper breast black; wing-coverts blackish, tipped white, tail with black subterminal band and white tip, crissum barred blackish. Female has crown and side of head grey, upperparts olive-brown, wings and tail dull rufous-brown, greater and median coverts thinly edged buff, tail edged russet; throat dingy white, underparts deep buff, deepest on flanks and crissum. Subadult male lacks black subterminal tailband. VOICE. Loudsong unusually complex for genus, 1-3 clusters of rapidly delivered, jumbled notes, descending in pitch

and lengthening, final emphatic notes upslurred, often introduced by sharp chips, duration 2-4 seconds (depending on number of clusters). Calls include variable (upslurred, downslurred, etc.) short whistles, given singly; also sharp chips, often in short series, or, in agonistic situations, widely spaced in longer series (over 20 notes) reminiscent of calls of some hummingbirds (Trochilidae).

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest and mature secondary woodland; to 900 m, mostly below 500 m. Perhaps most common at base of foothills (often on steep slopes), typically in shaded forest interior, with moss-covered trees, abundant epiphytes, and usually in close proximity to running water. Second-growth woodland occupied apparently only when mature, shaded, and connected to extensive primary forest.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage 1-12 m (mostly 4-8 m) above ground; sometimes alone, but usually with mixed-species flocks that include Lesser Woodcreeper (*Lepidocolaptes fuscus*), Black-capped (*Philydor atricapillus*) and White-eyed Foliage-gleaners (*Automolus leucophthalmus*), *Dysithamnus stictothorax* and *D. mentalis*, *M. unicolor*, and Red-crowned Ant-tanager (*Habia rubica*). Forages mostly in leafy crowns and peripheral portions of understorey trees, particularly those with medium-sized to large leaves, seldom in small-leaved trees; also along rachides of tree-ferns, from which it inspects the curled leaflets; rarely in herbaceous vegetation. Hops or hitches rapidly along thin branches, frequently flicking the wings and tail, methodically scanning leaves and stems, perch-gleaning from top and bottom surfaces of leaves by reaching and by short lunging stabs; also regularly by hanging from tips of large leaves, often for 1-4 seconds, while craning the neck to scan foliage; also routinely scans while perched atop larger leaves. Sometimes performs short (less than 40 cm) upward-directed hover-gleans or makes longer (to 1.5 m) diagonal sallies to tops and bottoms of leaves; often flutters down to glean prey from near ends of larger leaves before dropping to new perch, or flutters down to pursue dislodged prey. Most prey captured from live foliage; also regularly scans and gleans from arboreal dead leaves, usually by hanging vertically from a perch above, sometimes by clinging acrobatically to leaf itself; dead leaves seldom manipulated, although individuals may occasionally bite down on a portion of a dead leaf, presumably to startle prey hiding inside. Occasionally probes moss-covered trunks and strands of hanging *Usnea*.

**Breeding.** Little known. In Espírito Santo (Augusto Ruschi Biological Reserve), adults watched in Oct as they repeatedly carried food into site c. 1.5 m above ground in dense understorey thicket inside tall forest, but nest not found; adults occasionally feeding begging juveniles in São Paulo (near Ubatuba) in Oct.

**Movements.** Presumed resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Atlantic Forest Lowlands EBA. Uncommon to rare, and entire population considered to be at risk owing to loss of habitat. Although a number of protected areas exist within the species' range, most do not contain sufficient forest habitat in the relevant elevational range (below 300 m). Protected areas in which the species is known to occur include Tinguá and Poço das Antas Biological Reserves, Serra da Bocaina National Park, and the 315,000-ha Serra do Mar State Park, which straddles border between states of Rio de Janeiro and São Paulo. Last-mentioned is regarded as the single most important reserve for both this species and *M. unicolor*, and is contiguous with the privately held Fazenda Capricornio, where both also occur; vigorous protection of the park is particularly important, as it contains one of the few extensive lowland forests that is directly linked to the mountain slopes, thus providing a complete elevational transect of the forested habitats of the Serra do Mar. Extension of other existing reserves to include more forest below 300 m would also greatly benefit this thamnophilid, as well as many other species. Fazenda União, a c. 3000-ha lowland forest near Rocha Leão, in N Rio de Janeiro, and owned by Rede Ferroviária Federal S.A. (RFFSA), contains populations of this species and of *M. unicolor* and *M. urosticta*; although access is restricted, it is not officially protected; incorporation of this important forest into the formal reserve system would greatly benefit all three of these globally threatened antwrens. Efforts to shore up the protection of privately owned forests known to harbour populations of the present species are also needed. More surveys are required to assess its precise distribution and population levels in S Paraná, where forested slopes of the S Serra do Mar extend down to meet intact forest in the coastal plain; this region would appear to have great conservation potential for both this species and *M. unicolor*.

**Bibliography.** Aleixo (1999), Collar & Andrew (1988), Collar *et al.* (1994), Cory & Hellmayr (1924), Dunning (1993), Hackett & Rosenberg (1990), Isler & Whitney (2002), Nakagaki *et al.* (2000), Parker (2003a), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whitney (2003a, 2003b), Whitney & Pacheco (1995, 1997, 2003), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a).

## 87. Ihering's Antwren

### *Myrmotherula iheringi*

**French:** Myrmidon d'Ihering

**Spanish:** Hormiguerito de Ihering

**German:** Iheringameisenschlüpfer

**Taxonomy.** *Myrmotherula iheringi* Snethlage, 1914, Boim, Pará, Brazil.

Relationships uncertain. Often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Geographical distribution and diagnosability of races requires re-examination. Two subspecies recognized.

#### Subspecies and Distribution.

*M. i. heteroptera* Todd, 1927 - SW Amazonian Brazil (headwaters of R Juruá E to R Madeira), SE Peru (E Madre de Dios) and extreme NW Bolivia (W Pando).

*M. i. iheringi* Snethlage, 1914 - SC Amazonian Brazil (W bank of R Tapajós and along drainages of R Jiparaná and R Roosevelt S to Rondônia).

**Descriptive notes.** 8.5-9.5 cm; 7.5-9 g. Tail moderately short. Male is dark grey above, concealed white interscapular patch, black wing-coverts tipped white; throat, upper breast and centre of lower breast black (extent of black individually variable), rest of underparts grey, centre of belly whitish; underwing-coverts white. Female differs in being pale blue-grey above, throat whitish, underparts pale buff. Subadult male resembles female, but throat blotched black. Race *heteroptera* female has upperparts tinged ochraceous, wing-covert tips tinged buff. **VOICE.** Loudsong a countable series of intense, downslurred "peer"

notes, variably 6-30 (e.g. 24 notes, 13 seconds), notes and intervals essentially same length, pace and pitch nearly constant. Call a disyllabic "pe-weet", second syllable a sharp downslurred whistle; appears also to deliver second syllable on its own.

**Habitat.** Mid-storey and understorey of lowland evergreen forest (*terra firme* and transitional), to 400 m. Restricted to stands of *Guadua* bamboo in parts of range (e.g. SE Peru), but elsewhere inhabits mid-storey vine tangles, with or without bamboo. Appears to survive in disturbed areas with suitable micro-habitats.

**Food and Feeding.** Little published. Feeds on various insects, including orthopterans, stick-insects (Phasmatidae), and adult and larval Lepidoptera; probably also on spiders. Forages as closely associated pair-members, or individually, or in family groups, mostly 3-10 m above ground; mean foraging height in 44 observations in Peru (Cocha Cashu) was 5.1 m; 6.4 m in 63 observations in Brazil (Rondônia). Typically with mixed-species flocks of *Thamnomanes* antshrikes and other insectivores, but sometimes alone. Active forager, hitching from side to side, seldom pausing for more than 1 second between hops, often changing direction and retracing its route, while constantly flicking wings open and characteristically twitching tail rapidly from side to side. Frequently leans forward and cranes its head to peer under branches and leaves, gleaning prey from undersides of leaf petioles, vine stems, dead twigs, and leaves, by reaching or by acrobati-

cally clinging or hanging beneath stems, leaves or branches; sometimes makes short upward-directed sallies to hover-glean from underside of vegetation or branches. Where bamboo present, often gleans from its leaves, stems and nodes. Also regularly inspects and gleans from arboreal dead leaves, particularly of bamboo, but tends not to linger at these, nor does it manipulate them; in one study in Peru, dead leaves comprised 47% of foraging substrates in 219 observations; in 63 observations at a site in Rondônia (Brazil), where species not so closely tied to bamboo patches, only 27% of substrates were dead leaves, and 57% were twigs (mostly dead ones), stems and vines. Observations suggest that this species should be classed as a regular, non-specialist user of dead leaves.

**Breeding.** Almost nothing known. In Peru, copulation observed in Jul and juvenile found in Sept. Also record from Peru of nest-building on 3rd Oct, with single young fledged on 8th Nov; nest and eggs not described; male and female both incubated, shifts 4-5 hours; non-incubating partner joined mixed-species flock for foraging, even when more than 100 m from nest; later, when feeding nestlings, both parents foraged within 50 m of nest.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon and somewhat local throughout its range. Occurs in a few large, protected areas, notably Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Serra do Divisor and Tapajós National Parks, in Brazil. More surveys are needed in order better to assess the distribution and population status of this species in Brazil.

**Bibliography.** Alverson *et al.* (2000), Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Isler & Whitney (2002), Johns (1991), Kratter (1997a), Munn (1984, 1985), Munn & Terborgh (1979), Naumburg (1930), Oren & Parker (1997), Parker (1982, 2003a), Remsen & Parker (1984), Ridgely & Tudor (1994), Rosenberg (1997, 2003), Servat (1996), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Zimmer (2003a).

## 88. Rio de Janeiro Antwren

### *Myrmotherula fluminensis*

**French:** Myrmidon de Rio de Janeiro

**Spanish:** Hormiguerito Carioca

**German:** Rio de Janeiro-Ameisenschlüpfer

**Taxonomy.** *Myrmotherula fluminensis* Gonzaga, 1988, Santo Aleixo, Rio de Janeiro, Brazil.

Taxonomic validity questioned by various authors; was initially thought by some to be a hybrid between *M. unicolor* and race *luctuosa* of *M. axillaris*, and later considered possibly a variant of latter; moreover, some uncertainty over whether recent observations refer to same taxon as original type specimen. More research, including thorough analysis of recent tape recordings, is needed in order to determine its true taxonomic status. All mentioned taxa are often grouped with *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. behni*, *M. grisea*, *M. snowi*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Monotypic.

**Distribution.** C Rio de Janeiro, in SE Brazil.

**Descriptive notes.** c. 10 cm; 9 g. Male is grey, wings darker, throat and breast down to central belly black; wing-coverts black, broadly tipped white; underwing-coverts white; whitish eyering and subocular stripe. Female undescribed. **VOICE.** Nothing known; recorded vocalizations purported to be of this species considered very similar, if not identical, to those of race *luctuosa* of *M. axillaris*.

**Habitat.** Little known. Single specimen was collected in a partially isolated and highly disturbed woodlot at c. 20 m elevation; subsequent reports from young secondary forest (up to 25 years old) adjacent to old clearings, at 35-200 m.

**Food and Feeding.** Almost nothing known. Stomach of sole specimen contained remains of arthropods. Mainly seen feeding in mixed-species flocks, usually within 2 m of ground.

**Breeding.** Nothing known.

**Movements.** Nothing known; specimen was obtained from a lowland site that had been studied for 7 years, prompting speculation that bird was a straggler or altitudinal migrant from slopes of nearby Serra dos Órgãos.

**Status and Conservation.** CRITICAL. Restricted-range species: present in Atlantic Forest Lowlands EBA. Known from a single specimen taken in lowland Rio de Janeiro state. Reported to have been rediscovered in 1994 at Guapi Açu (then Serra do Mar) Ecological Reserve, which encompasses 74 km<sup>2</sup> of privately owned land at altitudinal range of 35-2000 m; the Fazenda do Mar (20 km<sup>2</sup>) forms core of this reserve, and adjacent landowners are expected to sign buffer-zone management agreements. Recent tape recordings made at Guapi Açu, alleged to be of this species, have been judged by several experienced field ornithologists to be very similar, even identical, to vocalizations of *M. axillaris* of race *luctuosa*, leading to published speculation that the Guapi Açu birds represent a local variant of that taxon; thorough analysis of tape-recorded vocalizations of the Guapi Açu individuals is required in order to determine if they are diagnosably different from *luctuosa*. Additional research needed to establish if these birds represent the same taxon as the type specimen. Further, the need for surveys aimed at locating any additional sites for this antwren and obtaining information on its ecology and conservation requirements is paramount. If it is, in fact, a forest bird, then habitat loss in this highly deforested region of Brazil is likely to be the most critical conservation issue.

**Bibliography.** Anon. (1997b), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Gonzaga (1988), Ridgely & Tudor (1994), Sick (1993), Stattersfield & Capper (2000), Teixeira (1997).

## 89. Plain-winged Antwren

### *Myrmotherula behni*

**French:** Myrmidon de Behn

**Spanish:** Hormiguerito de Behn

**German:** Graufügel-Ameisenschlüpfer

**Other common names:** Pale-winged Antwren

**Taxonomy.** *Myrmotherula behni* Berlepsch and Leverkühn, 1890, "Bogotá" trade skin, Colombia. Appears to be closely related to *M. grisea* on basis of habitat and vocalizations, also to *M. unicolor* and *M. snowi* of Brazilian Atlantic Forest, the four together termed the "Plain-winged *Myrmotherula* group". They are often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Four subspecies recognized.

#### Subspecies and Distribution.

*M. b. yavii* J. T. Zimmer & Phelps, Sr., 1948 - S Venezuela (NW Bolívar, Amazonas except Cerro Camani) and adjacent Brazil (extreme N Amazonas).

*M. b. camanii* Phelps, Sr. & Phelps, Jr., 1952 - Cerro Camani, in N Amazonas (Venezuela).

*M. b. inornata* P. L. Slater, 1890 - SE Bolívar and adjacent Brazil (extreme N Roraima); observations from the Guianas require confirmation.

*M. b. behni* Berlepsch & Leverkühn, 1890 - E Andean slope in SC Colombia (locally in Meta and Nariño) and E Ecuador (locally in Sucumbios, Napo and Pastaza).

**Descriptive notes.** 9.5 cm; 1 female 7.9 g. Male nominate race is grey, darker on wings; chin to centre of throat and upper breast black; underwing-coverts grey. Female has crown and upperparts olivaceous brown, tail slightly dusker, throat whitish, underparts drab olive-buff. Race *yavii* male is darker, female rear underparts dark olive-buff, darkest on flanks; *camanii* is paler than previous, female underparts less brown-looking; *inornata* is larger, male darker with more extensive black throat patch, female upperparts rufescent brown, rear underparts olivaceous brown. **VOICE.** Known only from Ecuador. Loudsong a series of simple, slightly downslurred notes on approximately same pitch (c. 4 kHz), notes longer than intervals (e.g. 9 notes, 4.5 seconds). Calls include sharp "wheet" and variably downslurred or upslurred squeals; calls sometimes repeated in pairs.

**Habitat.** Understorey and mid-storey of montane and foothill evergreen forest; 800-1600 m in Colombia and Ecuador, most common at c. 1000 m in Ecuador; 1000-1850 m in Venezuela and adjacent Brazil, most common at 1800-1850 m on Cerro de la Neblina. Observations from Ecuador suggest that species favours damp ravines with patches of bamboo (*Guadua*) in undisturbed forest.

**Food and Feeding.** Not well known; all information from Ecuador. Feeds on small insects, probably also spiders. Forages in pairs, individually, or in family groups, almost always with mixed flocks of other insectivores, including (locally) up to 5 congeneric species. In areas of forest with dense, interlocking understorey, seems to forage mostly 1-3 m above ground; in more open understorey tends to feed higher, 4-10 m. Forages actively, hopping and hitching along slender limbs, peering at undersides of leaves; frequently hangs aerobatically sideways or upside-down at tips or margins of leaves, often maintaining hanging position for several seconds while craning the neck to scan foliage. Prey gleaned by reaching, hanging, and short lunging stabs; occasionally by short flutter-chases. About 50% of all foraging manoeuvres directed at arboreal dead leaves, both single ones and small clusters; proportion of dead-leaf searching higher when foraging low in understorey than when in mid-storey; does not seem to manipulate dead leaves, so probably best classed as a regular, non-specialist user of dead leaves.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Rare and patchily distributed throughout its range. Reported sight records of race *inornata* from near sea-level in Guyana, Surinam and French Guiana require substantiation; species normally occurs at much higher elevations. Most recent records from Ecuador have been from Volcán Sumaco region, part of which is protected by the Sumaco-Galerías National Park. The species is also known from a number of tepuis in Venezuela, several of which fall within the boundaries of various parks and reserves (e.g. Alto Orinoco-Casiquiare Biosphere Reserve, and Canaima, La Neblina, Duida and Jaau-Sarisariñama National Parks), and all of which have been recently declared national monuments. More survey work is needed in order better to elucidate the distribution, ecology and conservation needs of this poorly known species.

**Bibliography.** Barnett *et al.* (2002), Cory & Hellmayr (1924), Hackett & Rosenberg (1990), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Sick (1993), Stotz *et al.* (1996), Whitney (1994a, 2003a), Whitney & Pacheco (1997), Willard *et al.* (1991).

## 90. Yungas Antwren

### *Myrmotherula grisea*

**French:** Myrmidon cendré

**Spanish:** Hormiguerito Ceniciento

**German:** Yungasameisenschlüpfer

**Other common names:** Ashy Antwren

**Taxonomy.** *Myrmotherula grisea* Carriker, 1935, Santa Anna, 2200 feet [670 m], La Paz, Bolivia. Appears to be closely related to *M. behni* on basis of habitat and vocalizations, also to *M. unicolor* and *M. snowi* of Brazilian Atlantic Forest, the four together termed the "Plain-winged *Myrmotherula* group". They are often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Monotypic.

**Distribution.** NE base of Andes in W Bolivia (La Paz, Cochabamba, W Santa Cruz).

**Descriptive notes.** 8.5-9.5 cm; 8-10 g. Male is uniform grey, except wings and tail darker, more brownish-grey; underwing-coverts light grey. Female is olive-brown above, crown to upper mantle tinged greyish, uppertail-coverts tipped yellowish-brown, tail dark brown, edged rufous-brown; side of head, chin and throat brownish-yellow, palest on chin, underparts yellow-ochre, browner on flanks and crissum; underwing-coverts pale buff. Subadult male differs from adult only in having patches of yellowish-brown. **VOICE.** Loudsong a series of simple, slightly downslurred notes on approximately same pitch (c. 4 kHz), delivered rapidly, notes much longer than intervals (e.g. 8 notes, 2-4 seconds); may sometimes be introduced by nasal calls (unconfirmed). Calls include sharp, upslurred "wheet" and upslurred doubled-noted "do-leep"; possibly also longer, flatter, raspy notes in groups of 2-4 (confirmation again required).

**Habitat.** Mid-storey and subcanopy of foothill evergreen forest and montane evergreen forest, also understorey at forest edge; at 500-1650 m. Probably most numerous in a narrow altitudinal band (c. 700-1200 m) above elevational limits of most congeners.

**Food and Feeding.** Little known. Feeds on various insects, including orthopterans and cockroaches (Blattidae), also spiders; adults seen carrying green orthopterans 2 cm long in bill. Forages in pairs, individually, or in family groups, 1-15 m above ground; observed both in mid-storey and lower canopy (mostly at 8-14 m) and in understorey (1-5 m up) at a stream edge. Very active and acrobatic; flicks wings constantly and tail occasionally. Appears primarily to search clusters of dead leaves hanging from open, slender branches or trapped in vine tangles; occasionally probes balls of moss on branches. Also observed to scan both sides of green leaves without taking prey. Recorded in mid-storey with mixed flocks of insectivores including Olivaceous Woodcreeper (*Sittasomus griseicapillus*), Tawny-crowned Greenlets (*Hylophilus ochraceiceps*), Golden-crowned Warblers (*Basileuterus culicivorus*), Guira Tanager (*Hemithraupis guira*), Red-crowned Ant-tanagers (*Habia rubica*) and Magpie Tanager (*Cissopis leveriana*); in understorey with flocks that included Ochre-cheeked Spinetail (*Poecilurus scutatus*), *Thamnomphilus aroyae*, *Dysithamnus mentalis* and Saffron-billed Sparrow (*Arremon flaviviridis*). At lower elevations associates with *M. axillaris* and *M. menetriesii*.

**Breeding.** Nothing known. Two paired individuals seen carrying orthopterans 2 m above ground in open undergrowth on 17th Aug, but no nest or young located.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Bolivian and Peruvian Lower Yungas EBA. Known from a small number of localities and a narrow elevational range within small geographical area, in which it is considered uncommon. The foothill yungas forests occupied by this species are drier than forests farther upslope, and therefore more easily cleared for colonization projects. Expanding cultivation of coffee and coca at same elevations provides further significant threat to the continued survival of this and other threatened species in the region. At present, only major protected area in which this thamnomphilid occurs is Ambaró National Park, in Santa Cruz; continued protection of the park, as well as creation of more yungas reserves, is urgently needed.

**Bibliography.** Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Gonzaga & Pacheco (1990), Hackett & Rosenberg (1990), Herzog (2003), Isler & Whitney (2002), Parker *et al.* (1992), Perry *et al.* (1997), Rensen (2003b), Rensen *et al.* (1982), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whitney & Pacheco (1997).

## 91. Unicoloured Antwren

### *Myrmotherula unicolor*

**French:** Myrmidon unicolore

**Spanish:** Hormiguerito Unicolor

**German:** Südlicher Einfarbameisenschlüpfer

**Taxonomy.** *Myrmothera unicolor* Ménétries, 1835, no locality = Rio de Janeiro, Brazil. Forms a superspecies with *M. snowi* and formerly treated as conspecific; also appears to be closely related to Andean *M. behni* and *M. grisea*. The four have together been termed the "Plain-winged *Myrmotherula* group"; this often combined with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Monotypic.

**Distribution.** SE Brazil (N Rio de Janeiro S to N Rio Grande do Sul).

**Descriptive notes.** 9-10 cm; 6.5-8.5 g. Male is grey, paler below; base of throat feathers black, tips grey. Female is olive-brown above, slightly greyer on crown and nape, uppertail-coverts yellowish-brown; wings dark greyish-brown, edged reddish yellow-brown, tail reddish yellow-brown; throat whitish, underparts mostly olive-buff, greyer on sides and flanks, crissum brownish-yellow. **VOICE.** Loudsong a series of simple, slightly downslurred notes on approximately same pitch (c. 4 kHz), notes longer than intervals (e.g. 9 notes, 4.5 seconds), song sometimes introduced by shorter nasal notes. Calls include sharp

"wheet", paired nasal notes, also longer, flat, raspy notes, sometimes in groups of 3-6.

**Habitat.** Understorey and mid-storey of lowland evergreen forest and mature second-growth woodland; locally (coastal São Paulo, Paraná and Santa Catarina) also in *restinga* woodland on white-sand soils; from sea-level to c. 500 m. Most common in somewhat stunted forest (canopy height 7-20 m) having dense, non-herbaceous understorey with abundance of thin trunks, vines and suspended dead leaves, often growing on sandy soils.

**Food and Feeding.** Little published. Feeds on small insects, including orthopterans (Tettigoniidae) and lepidopteran adults (moths) and larvae, also spiders. Closely associated pair-members, indi-

viduals, or family groups often forage alone, but more often with mixed-species flocks that include Lesser Woodcreeper (*Lepidocolaptes fuscus*), Plain Xenops (*Xenops minutus*), Black-capped (*Philydor atricapillus*) and White-eyed Foliage-gleaners (*Automolus leucophthalmus*), *Dysithamnus stictothorax* and *D. mentalis*, *Drymophila squamata* and Red-crowned Ant-tanager (*Habia rubica*); occurs locally in same flocks as *M. minor*. Foraging heights range from 0.5 m to 15 m; mostly 0.5–5 m in *restingas* woodland, but seldom below 3 m inside tall forest except at edges, where it may descend to near ground level. Moves actively but rather deliberately through trees, shrubs and (especially) vine tangles by hops and short flights, often pausing for 1–2 seconds to scan, and frequently flicking wings and tail; seldom changes course within a single tree, more often works in sustained direction, either hitching from low to high along vertical vines and branches or, when foraging along horizontal limbs, usually working from near the trunk outwards, constantly leaning to peer under leaves. Perch-gleans from top and bottom surfaces of live leaves, vines, stems and branches by reaches and short, lunging stabs; less frequently by hanging, or by short (usually 10–30 cm, rarely to 1 m) sallies or hover-gleans. Especially given to foraging in vine tangles and large philodendron (*Philodendron*) leaves along trunks, gleaning from petioles and vines. Also scans and gleans prey from arboreal dead leaves, usually by reaching from nearby perch with legs extended and neck craned, probing the curls lightly with the bill; less frequently clings to leaf itself. Extent of dead-leaf searching seemingly varies greatly among individuals, typically comprising 25–75% of total number of substrates used.

**Breeding.** Three nests found in Nov in São Paulo; juvenile-plumaged males seen in close company of adults in late Oct in Santa Catarina. Nest a cup, maximum dimensions 8.0 × 6.5 cm, height to 6.5 cm, constructed from roots, dead leaves and *Marasmius* filaments, also lined with *Marasmius*, with dead leaves hung on outside of structure, placed 0.82–2.08 m above ground in horizontal fork of shrub. Eggs in São Paulo white with wine-coloured spots and vermiculations, others variously described as having pale rusty-brown or darker purplish red-brown lines and scribbles and closely packed flecks; at approach of an observer, a male flew from a nest to the ground and fluttered its wings.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Atlantic Forest Lowlands EBA. Uncommon, and entire population considered to be at risk owing to loss of habitat. Although there are a number of formally protected areas within N part of its range (Rio de Janeiro and São Paulo), most do not contain sufficient forest habitat in appropriate elevational range (below 300 m). Protected areas in which the species is known to occur include Tinguá and Poço das Antas Biological Reserves, the lower reaches of Serra dos Órgãos National Park, Serra da Bocaina National Park, Ilha do Cardoso State Park, and the 315,000-ha Serra do Mar State Park. The last, which straddles border between states of Rio de Janeiro and São Paulo, is regarded as the single most important reserve for both this species and *M. minor*, and is contiguous with privately held Fazenda Capricornio, where both also occur; vigorous protection of Serra do Mar State Park is particularly important, as it contains one of the few extensive lowland forests directly linked to the mountain slopes, thus providing a complete elevational transect of forested habitats of the Serra do Mar. Extension of other existing reserves to include more forest below 300 m would also greatly benefit this and many other species. Fazenda União, a c. 3000-ha lowland forest near Rocha Leão, in N Rio de Janeiro, and owned by Rede Ferroviária Federal S.A. (RFFSA), contains populations of this antwren and also of *M. minor* and *M. urosticta*; this forest is not officially protected, but access is restricted; incorporation of this important forest into the formal reserve system would greatly assist the conservation of all three of these globally threatened antwrens. More survey work is needed in order to assess the distribution and population levels of present species in S portions of its range, particularly in the *S restingas* of Paraná and Santa Catarina, and in border region between the two states where forested slopes of S Serra do Mar are linked with intact lowland forest in the coastal plain. This region would seem to have great conservation importance, as evidenced by population levels of this species in the Volta Velha Reserve, at Itapoia (Santa Catarina); here, in Oct–Nov 2001, pairs or family groups were present in every understorey mixed flock and species was judged as fairly common.

**Bibliography.** Aleixo (1999), Belton (1985), Bencke & Kindel (1999), Buzzetti (2003b), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Cory & Hellmayr (1924), Hackett & Rosenberg (1990), Isler & Whitney (2002), Naka *et al.* (2000), Parker (2003a), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1967), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield & Capper (2000), Stotz *et al.* (1996), Teixeira & Gonzaga (1985), Whitney & Pacheco (1995, 1997), Zimmer (2003a).

## 92. Alagoas Antwren

### *Myrmotherula snowi*

**French:** Myrmidon de Snow

**German:** Nördlicher Einfarbameisenschlüpfer

**Spanish:** Hormiguerito de Alagoas

**Taxonomy.** *Myrmotherula unicolor snowi* Teixeira and Gonzaga, 1985, Pedra Branca, Alagoas, Brazil. Forms a superspecies with *M. unicolor* and formerly treated as conspecific; also appears to be closely related to Andean *M. behni* and *M. grisea*. The four have together been termed the “Plain-winged *Myrmotherula* group”; this often combined with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. longipennis*, *M. urosticta* and *M. menetriesii* as the “grey antwren assemblage”, although this grouping possibly not monophyletic. Monotypic.

**Distribution.** Alagoas, in NE Brazil: known only from type locality, above Muriç.

**Descriptive notes.** 10–10.5 cm; three birds 8–11.5 g. Male is grey, paler below; base of throat feathers black, tips grey. Differs from *M. unicolor* in longer, wider and deeper bill, longer wing, shorter tail. Female is mostly rufous-brown, darker on wing-coverts, with cheeks and throat paler; differs from *M. unicolor* in distinct rufescent tinge all over. **Voice.** Loudsong a series of simple downslurred notes of about even pitch (ca. 3–6 kHz), somewhat similar to that of *M. unicolor* but notes lower, more downslurred, and more often given in shorter groups of 3–6 notes (e.g. 4 notes, 4 seconds). Call a short “wheet”, also

longer, flat, nasal squealing notes in groups of 2–5, most often in triplets, notes descend in pitch. **Habitat.** Understorey of semi-humid upland forest, at c. 550 m.

**Food and Feeding.** Not well known. Feeds on insects, including orthopterans (Tettigoniidae) and lepidopteran larvae (greenish and whitish caterpillars); also on spiders. Stomach contents contained spiders, beetles (Coleoptera), cockroaches (Blattidae) and ants. Closely associated pair-members, individuals, or family groups forage 1.5–5 m above ground (mostly 5–8 m), sometimes alone, but usually with mixed-species flocks of insectivores, including Lesser Woodcreeper (*Lepidocolaptes*

*fuscus*), Plain Xenops (*Xenops minutus*), White-eyed Foliage-gleaner (*Automolus leucophthalmus*), *Thamnomanes caesi* and *Myrmotherula axillaris* (race *luctuosa*). Forages actively through vegetation with short hops and flights, hitching from side to side, frequently changing direction, seldom pausing for more than 3 seconds in one spot, and regularly flicking the wings and pumping tail downwards. Searches both live and dead foliage, gleaning prey from tops and bottoms of live leaves by reaches and short, lunging stabs; also hangs acrobatically by feet from leaf margins and tips; probes curled dead leaves with its bill, but does not otherwise manipulate them.

**Breeding.** Little known. Female with egg in oviduct on 9th Feb, and juveniles still in company of presumed parents recorded in May.

**Movements.** Presumed resident.

**Status and Conservation.** **CRITICAL.** Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Known only from the Muriç Ecological Reserve (3000 ha), where it is uncommon. Surveys of the few remaining ridgetop forests in the region are urgently required in order to locate any additional populations of this species. Even more important is the urgent need for adequate protection of the reserve, which was still subject to illegal timber extraction in Jan 2002. This reserve is a critical reservoir of endemic biodiversity, from which four species of passerine have been described as new to science since 1983.

**Bibliography.** Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Isler & Whitney (2002), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Teixeira & Gonzaga (1985), Wege & Long (1995), Whitney & Pacheco (1995, 1997), Zimmer (2003a).

## 93. Long-winged Antwren

### *Myrmotherula longipennis*

**French:** Myrmidon longipenne

**Spanish:** Hormiguerito Alilargo

**German:** Silberameisenschlüpfer

**Other common names:** Garbe's Antwren (*garbei*)

**Taxonomy.** *Myrmotherula longipennis* Pelzelin, 1868, Marabitanas, Rio Negro, Amazonas, Brazil. Forms a superspecies with *M. urosticta*; other relationships uncertain, but appears closely related to *M. menetriesii*. The three are often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor* and *M. snowi* as the “grey antwren assemblage”, although this grouping possibly not monophyletic. Plumage and vocal differences suggest that some races may be separate species; taxa in need of re-examination; geographical ranges of races tentative, based mainly on previously published statements. Six subspecies recognized.

**Subspecies and Distribution.**

*M. l. longipennis* Pelzelin, 1868 - S Venezuela (Bolívar, Amazonas), the Guianas, N Amazonian Brazil (E to Amapá), SE Colombia, extreme NE Ecuador (N of R Napo) and extreme N Peru (Loreto N of R Napo and R Amazon).

*M. l. zimmeri* Chapman, 1925 - E Ecuador (S of R Napo) and NE Peru (S of R Napo, N of R Amazon and R Marañón).

*M. l. garbei* H. von Ihering, 1905 - E Peru (S of R Amazon & R Marañón), SW Amazonian Brazil (E to R Madeira) and NW Bolivia (Pando, La Paz).

*M. l. ochrogyna* Todd, 1927 - lower R Madeira E to R Tapajós.

*M. l. paraensis* (Todd, 1920) - from R Tapajós E to W Maranhão, S to NE Mato Grosso.

*M. l. transitiva* Hellmayr, 1929 - SC Brazil (Rondônia, SW Mato Grosso).

**Descriptive notes.** 9–10.5 cm; 8–10 g. Male nominate race is dark grey, paler below, concealed white interscapular patch; wing-coverts black, tipped white, scapulars and tail tips narrowly edged white, throat and upper breast black, underwing-coverts light grey. Female is olive-brown above, wings and tail dark greyish-brown, flight-feathers and wing-coverts edged deep cinnamon; head side ochraceous buff, throat and breast light buff, lower underparts white, tinged grey, flanks olive-tinged light grey. Subadult male (possibly first-year) is like female, but posterior underparts light grey. Races differ from nominate in male having

white-tipped feathers on head side, black extending farther down breast, slightly paler underparts, female more variably different: *zimmeri* female has crown and upperparts olive-tinged grey, tail dark grey, flight-feather edges cinnamon-tinged white, contrasting pale cinnamon tips of wing-coverts, head side pinkish-buff, deep cinnamon below; *garbei* male has slightly paler rear underparts, female resembles previous but more olivaceous above, wing-covert tips olive-buff, head side paler, warm buff below; *ochrogyna* male has lower underparts slightly darker than previous, female crown and upperparts rufous-brown, tail brown, head side buff-brown, ochraceous below; *paraensis* male has pale grey rear underparts often tipped white, female is brownish-olive above and on wing and tail edgings, head side cinnamon-buff, bright cinnamon-buff below, immature like female but greyer above and grey lower underparts (first-year?), or like male but throat white with indistinct black spots (second-year?); *transitiva* is somewhat darker ventrally than previous, female is similar but more rufescent above, head side paler, light buff below, deepest on breast, shaded brownish on flanks. **Voice.** Loudsong nominate race a series of harsh upslurred notes (e.g. 10 notes, 5–5 seconds), initially gains in intensity but nearly constant in pitch and pace; *garbei* a deliberate series (e.g. 5 notes, 3 seconds), each note dropping and then rising in pitch, sounding like “cheery”, while entire series rises in pitch, song sometimes introduced by harsh downslurred notes; *zimmeri* most resembles previous; *paraensis* a rapidly delivered series of abrupt downslurred notes that shorten slightly in length, mostly on same pitch except last notes rise (e.g. 9 notes, 2.6 seconds); *transitiva* most resembles previous, as also do notes of *ochrogyna* (but pitch rising and pace faster in latter, more like *garbei*). Common call consists of 2–6 whistles, dropping in pitch, the number and length of notes variable among races and individuals; also variety of shorter notes.

**Habitat.** Understorey and mid-storey of lowland and foothill evergreen forest, primarily *terra firme*, but also transitional and *várzea*/igapó, mostly below 700 m; to 900 m in Andes, to 1100 m in tepuis of Venezuela. Most common in relatively open, shaded understorey of tall *terra firme* forest.

**Food and Feeding.** Feeds on variety of insects and spiders. Stomach samples from Surinam contained lepidopteran larvae, beetles (Chrysomelidae), ants (Myrmicinae), orthopterans (Acrididae), spiders. Analysis of stomach contents of 12 birds from Peru/Bolivia revealed that commonest prey were katydids (Tettigoniidae) and crickets (Gryllidae), followed in order by larvae, beetles (virtually all less than 10 mm), spiders, cockroaches (Blattidae) and heteropterans, and ants/flies/wasps; in same extensive study, comparisons of prey taken in the field with prey availability showed that orthopterans, beetles and larvae were selected more than expected, and many fewer ants, flies and

wasps taken than would be predicted on basis solely of availability; in the same prey-selectivity experiment, but using birds in outdoor cages, cockroaches, spiders, crickets, katydids smaller than 25 mm, some grasshoppers, butterflies (Lepidoptera) and dragonflies (Odonata) were readily captured and consumed, but harvestmen (Opiliones), nearly all ants, flies and wasps, most beetles and heteropterans, and katydids larger than 25 mm were ignored or rejected. Closely associated pair-members, individuals, or family groups forage mostly 2-8 m above ground, sometimes lower, and rarely to 14 m; mean foraging height from 90 observations in Peru (Cocha Cashu) was 4.6 m; means in Brazil 5.6 m from 175 observations in Rondônia and 6.2 m from 162 observations near Manaus. Sometimes alone, but usually with mixed flocks of other insectivores, including *Thamnomanes* antshrikes, other antwrens, woodcreepers (Dendrocolaptidae), foliage-gleaners (Furnariidae), Tawny-crowned Greenlet (*Hylophilus ochraceiceps*) and Red-crowned Ant-tanager (*Habia rubica*). Forages mostly along slender, relatively open branches of understorey trees, particularly those with medium-sized to large leaves, usually starting in centre of tree and then working outwards, hitching from side to side along lateral branches while scanning live leaves and stems, and frequently leaning forward to peer under leaves and branches; continually flicks wings and wags tail slowly from side to side. Mostly perch-gleans prey from live leaves, stems, petioles and branches, either by reaching or by short, lunging stabs; sometimes hangs head first from tips of larger leaves to glean prey below. Frequently makes short, upward-directed sallies to hover-glean from underside of overhanging vegetation, sometimes fluttering back up to glean multiple times from same spot; this technique often used to extract lepidopteran larvae or eggs from inside silk casings, also at large leaves with visible insect damage (perhaps signalling an infestation). Regularly scans arboreal dead leaves, but more frequently ignores them. Where occurring in same flocks as *M. axillaris*, spends less time in vine tangles and dense foliage, and sallies and hover-gleans much more than that species.

**Breeding.** Nests found in Aug (2) and Dec (1) in French Guiana and in Aug-Nov in SE Peru (4). In French Guiana, nest built mainly by female, a deep cup (4.2 cm internal, 8 cm external) constructed mostly of fungal (*Marasmius*) fibres, covered with dead leaves, one 12 m above ground in tree covered with lianas and epiphytes, another 6 m above ground; in Peru, an open cup placed 2-6 m up in fork of leafy sapling. Both sexes feed chicks, bringing insects (including cockroach) and spiders from distances 30-40 m from nest, rather than farther away while accompanying mixed flocks.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Considered to be fairly common throughout most of its range. Extensive range includes a number of large, protected areas, such as Alto Orinoco-Casiquiare Biosphere Reserve, Yapacana and La Neblina National Parks, in Venezuela, Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Serra do Divisor, Jau and Tapajós National Parks, Cristalino State Park and Caxiuanã National Forest, in Brazil. In addition, there are vast areas of contiguous appropriate habitat which are not formally protected, but which appear to be under relatively little threat of development in immediate future.

## 94. Band-tailed Antwren

### *Myrmotherula urosticta*

**French:** Myrmidon à queue blanche

**Spanish:** Hormiguerito Atlántico

**German:** Schwarzbinden-Ameisenschlüpfer

**Taxonomy.** *Formicivora urosticta* P. L. Selater, 1857, eastern Brazil.

Forms a superspecies with *M. longipennis*; other relationships uncertain. The two are often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi* and *M. menetriesii* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Monotypic.

**Distribution.** Coastal E Brazil from C Bahia S to N Rio de Janeiro.

three notes, series dropping in pitch.

**Habitat.** Understorey and mid-storey of lowland evergreen forest, to c. 500 m. Seemingly more common in taller forest growing on sandy soils and with seasonal distribution of rainfall; within these, appears to prefer areas with abundance of vines in understorey and mid-storey.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly 3-10 m above ground, rarely to 20 m; mean foraging height from 119 observations at Espirito Santo site was 4.9 m. Sometimes alone, but typically with mixed-species flocks of other insectivores that usually include *Thamnomanes caesi* and virtually always include *Myrmotherula axillaris* (race *luctuosa*). Forages mostly in more open, leafy branches with moderate foliage density. When moving to a new tree, usually flies to centre and then slides out along horizontal limbs, hitching sideways with the body perpendicular to the limb and making several short hops without changing its orientation; alternatively, hitches from side to side up vertical vines and inclined limbs until reaching crown, then flies down to mid-level of another tree. Active forager, scanning foliage as it goes, frequently flicking its wings. Perch-

**Descriptive notes.** 9-10 cm. Male is grey, paler below, concealed white interscapular patch; tail darker with white band at tip, wing-coverts black, tipped white, throat and upper breast black, underwing-coverts light grey. Female differs from male in paler grey head and upperparts, wing-coverts grey (not black), throat white, pale cinnamon-buff below, sides and flanks grey. Voice. Loudsong a deliberate series (e.g. 8 notes, 5.8 seconds) resembling that of race *garbei* of *M. longipennis*, except individual notes raspier and rise and fall more evenly, and pitch of entire song does not rise so much. Calls also similar; common call of

gleaning from tops of live leaves by far the most common attack manoeuvre; also regularly hangs with legs and neck extended to glean prey from tops of leaves. Less frequently, reaches upwards or makes short fluttering hover-gleans to take prey from undersides of leaves, or makes diagonal sallies of up to 1.5 m to both tops and bottoms of leaves; sometimes spots prey from a distance, then sallies to a perch adjacent to prey and captures it with a short, lunging stab (sally-pounce); also sometimes dislodges prey (usually orthopterans), then suddenly flutters downwards in rapid pursuit. Occasionally reaches out, up or down to probe lightly into curled dead leaves, but this behaviour relatively rare.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** ENDANGERED. Restricted-range species; present in Atlantic Forest Lowlands EBA. Uncommon and local, with patchy distribution, within its very small range. Currently known primarily from five protected areas in S Bahia totalling c. 43,000 ha (Monte Pascoal National Park, Una Biological Reserve, Porto Seguro Forest Reserves, and CPEC Gregorio Bondar Reserve), and from Sooretama Biological Reserve and the Linhares Natural Reserve (together totalling c. 46,000 ha) in N Espírito Santo. Significant portions of these reserves encompass habitat not suitable for this species, for which the effective protected area is therefore much smaller than it may seem. Has also been found at Fazenda União, a c. 3000-ha lowland forest located near Rocha Leão, in N Rio de Janeiro, and owned by Rede Ferroviária Federal S.A. (RFFSA). Although access is restricted, this forest is not officially protected; incorporation of this important forest into the formal reserve system would provide an important protected area for the species at the S end of its range. Surveys to locate additional, unprotected lowland-forest sites with remaining populations of this thamnophilid, followed by acquisition and protection of such lands, are greatly needed, as is continued protection of the integrity of existing reserves.

**Bibliography.** Collar *et al.* (1994), Cory & Hellmayr (1924), Hackett & Rosenberg (1990), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Parker (2003a), Parker & Goerck (1997), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz (1990b), Stotz *et al.* (1996), Whitney & Pacheco (1995, 1997), Willis (1984a), Zimmer (2003a).

## 95. Grey Antwren

### *Myrmotherula menetriesii*

**French:** Myrmidon gris

**German:** Blassgrauer Ameisenschlüpfer

**Spanish:** Hormiguerito Gris

**Other common names:** Ménétries's Antwren

**Taxonomy.** *Myrmothera Menetriesii* d'Orbigny, 1837, Yuracares, Bolivia.

Relationships uncertain, but appears to be closely related to *M. longipennis*. The two are often grouped with *M. axillaris*, *M. schisticolor*, *M. sunensis*, *M. minor*, *M. iheringi*, *M. fluminensis*, *M. behni*, *M. grisea*, *M. unicolor*, *M. snowi* and *M. urosticta* as the "grey antwren assemblage", although this grouping possibly not monophyletic. Pending further study, geographical ranges of races follow those given by previous authors, but some races possibly not diagnosable. Five subspecies recognized.

**Subspecies and Distribution.**

*M. m. pallida* Berlepsch & Hartert, 1902 - SW Venezuela (W Bolívar, Amazonas), NW Brazil (Roraima and Amazonas N of R Amazon), E Colombia, E Ecuador and NE Peru (N of R Amazon and R Marañón).

*M. m. cinereiventris* P. L. Selater & Salvin, 1868 - SE Venezuela (E Bolívar), the Guianas and NE Amazonian Brazil (Amapá, N Pará).

*M. m. menetriesii* (d'Orbigny, 1837) - EC & SE Peru (S of R Amazon and R Marañón), SW Amazonian Brazil (E to R Madeira, S to Acre) and NW Bolivia (W Pando, La Paz, and along base of Andes to W Santa Cruz).

*M. m. berlepschi* Hellmayr, 1903 - SC Amazonian Brazil (R Madeira E to R Tapajós and S to Rondônia) and extreme NC & NE Bolivia.

*M. m. omissa* Todd, 1927 - from R Tapajós E to W Maranhão.

**Descriptive notes.** 8.5-9.5 cm; 8-9 g. Male nominate race is bluish-grey, paler below; wing-coverts with black subterminal bar and white tip, tail narrowly tipped white; centre of throat black, usually with grey feather tips, upper breast with black patch. Female has grey upperparts tinged olive, wings darker, buff throat, rich ochre-buff below, including breast. Juvenile resembles female, but duller and darker; subadult male has upperparts like adult except wings tinged buff, patchily pale grey and pale buff below, sides and flanks buff-tinged olive, crissum buff. Race *berlepschi* male is similar to nominate but less bluish, tail with blackish

subapical band, female is more cinnamon-rufous above, wing edgings cinnamon, richer-coloured tawny-ochraceous below; *cinereiventris* male lacks black on throat and breast (occasionally spots on breast), female upperparts brownish-olive, underparts like nominate; *omissa* resembles previous, female underparts yellow-ochre; *pallida* male is paler than last, especially below, crissum whitish, female similar to nominate. Voice. Loudsong nominate race a series of clear long whistles (e.g. 13 notes, 9 seconds) that are flat initially, gradually shortening slightly while becoming more upslurred, intensity increasing initially, rather low-pitched compared with most congeners (e.g. 1.8-3.3 kHz); *cinereiventris* similar but at higher pitch and rising more (e.g. 2.5-4 kHz), notes becoming downslurred and shortening more, so that acceleration greater (e.g. 12 notes, 6 seconds). Calls multi-noted, include higher-pitched abrupt notes and lower, slightly longer ones in varying combinations, e.g. a low-pitched note, multiple high-pitched notes, and a final low-pitched note or series of high notes, then 2-3 low-pitched notes; all variations delivered rapidly.

**Habitat.** Mid-storey and subcanopy of lowland evergreen forest, both *terra firme* and transitional, locally as high as 1000 m.

**Food and Feeding.** Feeds on variety of insects, including orthopterans (Acrididae), beetles (Coleoptera); also spiders. Caterpillar seen fed to juvenile. Closely associated pair-members, individuals, or family groups forage mainly 6-20 m above ground, sometimes down to 3 m and up to 25 m; mean foraging height from 24 observations in Peru (Cocha Cashu) was 8.9 m; means in Brazil 8.5 m from 247 observations in Rondônia and 10.8 m from 189 observations near Manaus. Almost always with mixed-species flocks led by *Thamnomanes* antshrikes, and mostly above heights used by *M. longipennis* and *M. axillaris*, which usually in same flocks. Very active forager, often almost frenetic in pace, hitching rapidly through mostly slender to medium-sized leafy branches and also in vine tangles hanging alongside major trunks; regularly twitches its tail sideways (similar to tail movements of *M. iheringi*, but much less habitual), also flicks its wings. Frequently leans forward

and cranes neck to peer under leaves, also stretches to peer over leaves; gleans prey from tops and bottoms of live leaves (primarily), stems and vines by reaches or head-first hangs from leaves, stems and branchlets; also commonly makes short diagonal or vertical sallies to bottoms of leaves, often hovering momentarily at apex of sally. Occasionally pauses to scan arboreal dead leaves, but more often ignores them.

**Breeding.** Nests found in Feb in Colombia (Mitú) and Venezuela (Amazonas); juvenile being fed by adults in Dec in French Guiana and in Jul in Bolivia (Pando). Nest composed mostly of dead leaves, wrapped and suspended in fork, in Colombia 4-5 m above ground, in Venezuela 10 m above ground; nest in Madre de Dios, Peru (details previously unpublished), was greyish ball of leaves, c. 7-5 cm in diameter, placed within proximity of larger dark leaves, suspended 8 m up from bifurcation at end of tree limb overhanging a trail, female observed bringing bundles of spider webs to nest. Egg white with very fine brown spots, these condensing into wreath at blunt end.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common to common over most of its large range. Numerous large, protected areas exist within regions inhabited by this species, examples being Alto Orinoco-Casiquiare Biosphere Reserve and Yacapana and La Neblina National Parks, in Venezuela, Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam, Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Serra do Divisor, Jaú and Tapajós National Parks, Cristalino State Park and Caxiuanã National Forest, in Brazil. Moreover, there are vast areas of contiguous appropriate habitat which, while not formally protected, appear to be under little threat of development in the near future.

**Bibliography.** Álvarez (1994), Alverson, Moskovits & Shopland (2000), Alverson, Rodríguez & Moskovits (2001), Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Dick *et al.* (1984), Foster *et al.* (1994), Gonzaga (2001), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Killeen & Schulenberg (1998), Mason (1996), McQueen (2003), Meyer de Schauensee & Phelps (1978), Munn (1984, 1985), Munn & Terborgh (1979), Nehrkorn (1914), Novaes (1965, 1969, 1980), Oniki & Willis (1983b), Oren & Parker (1997), Parker (2003a), Pearson (1975c, 1977a), Powell (1989), Rensen (1986, 2003b), Rensen *et al.* (1986), Reynaud (1998), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg (2003), Schönwetter & Meise (1967), Servat (1996), Sick (1993), Stotz (1990b), Stotz & Bierregaard (1989), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Stouffer & Bierregaard (1995), Tallman, D.A. & Tallman (1997), Tallman, E.J. & Tallman (1994), Terborgh & Weske (1969), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Thiollay (1988a, 1994), Tostain (2003), Valente (2000), Wiley (1980), Willis (1977), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a), Zimmer, K.J. & Hilty (1997).

## 96. Leaden Antwren

### *Myrmotherula assimilis*

**French:** Myrmidon plombé **German:** Värzeaameisenschlüpfer **Spanish:** Hormiguero Plomizo  
**Other common names:** White-backed Antwren

**Taxonomy.** *Myrmotherula assimilis* Pelzelin, 1868, Rio Amajau, Rio Negro, Brazil. Relationships uncertain. Results of one genetic study suggest that this species is not related to any others in the genus. Two subspecies recognized.

#### Subspecies and Distribution.

*M. a. assimilis* Pelzelin, 1868 - rivers of W & C Amazonia in Peru (E from lower R Marañón), Brazil (E to Amazonas-Pará border, including R Solimões, R Madeira and lower portions of R Negro, R Jurua and R Purus) and N Bolivia (lower R Beni and R Guaporé).

*M. a. transamazonica* Gyldenstolpe, 1951 - R Amazon in extreme W Pará (E to mouth of R Tapajós).

**Descriptive notes.** 9-10 cm; 8.5-9.5 g. Male is grey, paler below; large white interscapular patch; wing-coverts slightly darker grey, narrowly edged white, tail rather narrowly tipped white. Female is grey above, wings and tail dark brownish-grey, remiges edged pale brown, wing-coverts tipped buff-tipped white, tail very narrowly tipped pale buffish-white, throat whitish, underparts buff. Race *transamazonica* male is distinctly paler, especially upperparts, and wing longer. Voice. Loudsong a trill of extremely rapidly delivered notes (e.g. 55 notes, 3-5 seconds), accelerates throughout, intensity increases slowly at beginning and

drops quickly at end, pitch rises slightly at beginning and falls more sharply at end. Call a short, downslurred "snew", emphatic and somewhat harsh.

**Habitat.** Understorey and mid-storey of lowland evergreen forest and adjacent scrub at river edges. Occurs in both várzea and igapó forest, both on river islands and along river borders of land. On river islands primarily in interior of older forest or more mature stands of secondary woodland, but may occasionally venture into adjacent younger second growth to forage.

**Food and Feeding.** Little published. Feeds on various insects, particularly orthopterans and adult and larval lepidopterans; probably also on spiders. Clips wings from adult lepidopterans before consuming them; similarly, removes legs from large orthopterans, mainly katydids (Tettigoniidae), and mandibulates these extensively (30-60 seconds) before swallowing. Closely associated pair-members, individuals, or family groups forage mostly at 1-5-7 m, less commonly down to ground, rarely up to 15 m or higher; frequently alone, sometimes with mixed-species flocks. Seems to prefer inner portions of tree profile, spending most time working more open branches and, especially, hanging woody vines; moves vertically more than horizontally, but often in zigzag fashion and retracing route, hitching from side to side as it goes, and routinely flicking the wings and tail; moves actively, but rather deliberately, pausing frequently between hops for 1-2 seconds to scan. Prey taken at least as often from stem, branch or vine surfaces as from leaves, usually by direct perch-gleans, sometimes by short sally-gleans or hover-gleans; also frequently leans forward and peers under branches, or hangs upside-down to glean prey below; also regularly drops to ground to take prey from surface of leaf litter. Arboreal dead leaves regularly scanned and probed, but also

frequently ignored; many dead leaves scanned by craning the neck and peering into the curl without inserting the bill.

**Breeding.** Nothing known. Adult male seen to feed begging juvenile on 11th Oct in Brazil (Anavilhanas Archipelago, on R Negro).

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common but patchily distributed throughout its narrow, somewhat linear range, which extends along much of R Amazon and portions of its major tributaries. There are few formally protected reserves or parks which incorporate the river-island and river-edge flooded forests occupied by this species. Probably the largest of these is Rio Negro State Park (4360 km<sup>2</sup>), which encompasses the Anavilhanas Archipelago, an extensive and largely pristine series of black-water river islands in which this antwren is common; this park is contiguous with Jaú National Park (22,720 km<sup>2</sup>), which also contains extensive suitable habitat. River islands and várzea forests where the species occurs along the Amazon, Jurua, Purus and Madeira rivers, even where under no formal protection, are subject to generally low levels of human colonization and disturbance.

**Bibliography.** Álvarez (1994), Cory & Hellmayr (1924), Hackett & Rosenberg (1990), Hilty & Brown (1986), Isler & Whitney (2002), Parker (2003a), Parker *et al.* (1991), Rensen & Parker (1983), Ridgely & Tudor (1994), Rosenberg, G.H. (1990), Sick (1993), Stotz *et al.* (1996), Zimmer, J.T. (1932b), Zimmer, K.J. (2003a).

## Genus *DICHROZONA* Ridgway, 1888

## 97. Banded Antbird

### *Dichrozona cincta*

**French:** Grisin sanglé **German:** Bürzelbinden-Ameisenfänger **Spanish:** Hormiguero Bandeado  
**Other common names:** Banded Antwren/Antcatcher

**Taxonomy.** *Cyphorhinus (Microcerulus) cinctus* Pelzelin, 1868, São Joaquim, Amazonas, Brazil. Relationships uncertain. Specimens from extreme ends of range differ in plumage coloration; named races *stellata* (E Ecuador, W Brazil) and *zononota* (WC Brazil, N Bolivia) described primarily on basis of darkness and coloration of crown and back, darkness and extent of grey on flanks, and size and number of breast spots, but comparative documentation considered insufficient; further study required to determine whether any geographical races, with defined distributions, are recognizable. Monotypic.

**Distribution.** Extreme SW Venezuela (SW Amazonas), SC & E Colombia (along E base of Andes S from Meta, and in extreme E Guainía), E Ecuador, E Peru, and extreme NW and S Amazonian Brazil (upper R Negro drainage, and from W Amazonas E to Pará in the R Xingu drainage and S to Acre and N Rondônia) S to NW Bolivia (Pando, Beni, La Paz).

**Descriptive notes.** 9-10 cm; 14-15.5 g. Long bill, short tail. Male has thin white supercilium, blackish line through eye, greyish cheek to neck side; crown to upper back cinnamon-brown (variably darker or browner), lower back to uppertail-coverts banded black, white, black, grey; white interscapular patch; wings black, flight-feathers edged cinnamon to chestnut, wing-coverts tipped buff to white; tail black, outer rectrices mostly white; white below, band of black spots across breast, flanks brownish-grey, variable, e.g. more and larger spots and more extensive and darker grey in W ("*stellata*"). Female is similar to male, but

band across lower back buff, underparts tinged buff, fewer breast spots. Voice. Vocalizes from ground, or low stump or log. Loudsong a long series of drawn-out notes (e.g. 16 notes, 15 seconds) that become more intense, shorten slightly and rise in pitch gradually, intervals much shorter than notes. Calls include short whistle rising, falling, then rising up scale, sounding like "wheee-up", also variable-length (e.g. 0.5-1 second) rattle.

**Habitat.** Floor of lowland evergreen forest, to 800 m. Mainly, if not entirely, in *terra firme* forest, with preference for slopes with relatively open understorey and well-developed layer of leaf litter.

**Food and Feeding.** Not well known. Probably feeds on various insects and other arthropods. Terrestrial; walks slowly on forest floor, forages mainly by stabbing and probing in leaf litter, peering under leaves, and sometimes flipping leaves with its bill to reveal concealed prey. Occasionally reaches up or jumps up to glean items from overhanging stems or leaves. While walking, bobs head forwards, also occasionally fans tail to expose white outer feathers and flicks wings to expose white patch on back. Jumps up to small saplings to look around, and sometimes on to tree stumps or fallen logs to vocalize.

**Breeding.** Little known. Single described nest from E Ecuador, an open cup placed 0-1 m above ground in fork of low bush in forest; two tiny, bob-tailed fledglings seen in area in late Nov.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Status not well known; generally considered uncommon and somewhat locally distributed throughout its extensive range. Range encompasses several protected areas with vast expanses of suitable habitat, e.g. Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Serra do Divisor and Tapajós National Parks and Caxiuanã National Forest, in Brazil, and Madidi National Park, in Bolivia. In addition, there are huge areas of contiguous appropriate habitat that are not formally protected, but are under little threat of development in the near term.

# Genus *MYRMORCHILUS* Ridgway, 1909

## 98. Stripe-backed Antbird

### *Myrmorchilus strigilatus*

**French:** Grisin à dos rayé

**German:** Strichelrücken-Ameisenfänger

**Spanish:** Hormiguero Estriado

**Taxonomy.** *Myiothera strigilata* Wied, 1831, Bahia, Brazil. Relationships uncertain. Two subspecies recognized.

#### Subspecies and Distribution.

*M. s. strigilatus* (Wied, 1831) - NE Brazil (extreme E Piauí, C Ceará and Rio Grande do Norte S to N Minas Gerais).

*M. s. suspicax* Wetmore, 1922 - SE Bolivia (S Santa Cruz S to Tarija), adjacent Brazil (extreme SW Mato Grosso, W Mato Grosso do Sul), W Paraguay (W of R Paraguay) and N Argentina (W of R Paraná, S to Santiago del Estero and Santa Fe).

**Descriptive notes.** 15-16 cm; 23-26 g. Male has white supercilium, dark line through eye; crown to back rufous, streaked black, outer scapulars edged white, rump and uppertail-coverts rufous; tail rufous and black, white tip and outer edges; wings black, flight-feathers partly edged rufous, wing-coverts tipped white; chin, throat and breast black, remaining underparts white, sides and flanks spotted black, crissum tinged buff. Female lacks black on chin to breast, is more buff below, streaked on sides and lightly on breast. Race *suspicax* male has supercilium tinged buff, flanks and crissum buff, female has supercilium brownish, flanks and crissum deeper buff. **Voice.** Loudsong of male brief (e.g. 0-8 seconds), a short, somewhat rough note followed after an interval by 2 longer whistles, each rising and falling in pitch, final note longest; female song longer (e.g. 2-4 seconds), starts with similar note followed by long second note, then c. 6 notes declining in pitch and intensity. Call a long (e.g. 0-35-0-5 seconds) whistle, entirely downslurred or slightly rising and falling.

**Habitat.** Ground and understorey of deciduous Chaco and *caatinga* woodlands and scrub, to 1100 m. Most common where canopy height exceeds 2 m and interlacing branches of trees and shrubs form fairly continuous canopy, often with abundant ground cover of terrestrial bromeliads.

**Food and Feeding.** Little published. Feeds on insects, possibly also other arthropods. Pairs or individuals forage mostly on the ground beneath dense shrubbery and low trees, occasionally climbing up in vegetation to heights of 1-2 m. Forages in dry leaf litter and clumps of terrestrial bromeliads, picking through litter with its bill, occasionally vigorously kicking with its feet to stir up litter. Perch-gleans prey by reaching and picking; sometimes makes short, wing-assisted jumps to glean prey from underside of overhanging foliage, branches or vines.

**Breeding.** Little known. Single nest described from Argentina (Santiago del Estero), an open cup 4 cm deep, with inside diameter 9 cm, external diameter 10-5 cm, loosely built of dry grasses (*Setaria*) with lining of garabato (*Acacia praeox*) rachides, placed on ground on freshly opened path in mature secondary woodland; 2 eggs, pale pink, with maroon blotches concentrated mainly on larger end.

**Movements.** Presumed resident in both parts of range.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its disjunct Chaco and *caatinga* ranges. Although species is under no immediate threat, there are relatively few reserves or parks protecting these dry-forest and arid-scrub habitats, which are subject to increasing pressure from expanding human populations, and which have traditionally been considered low conservation priorities at both national and international levels. Conversion to agriculture, grazing by cattle and goats, and removal of woody vegetation for firewood are primary threats facing both the Chaco and the *caatinga* biomes and their highly endemic avifaunas. Establishment of a proposed "mata-de-cipó" reserve in Boa Nova-Jequié region of Bahia, Brazil, would protect a significant population of nominate race, as well as viable populations of more threatened antbirds, such as globally threatened *Formicivora theringi* and *Rhopornis ardesiacus*. Similar reserves needed in the Alto Chaco and Matogrossense regions of N Paraguay and in Bolivian Chaco of Santa Cruz; these would provide important refuges for a number of endemic birds, among them race *suspicax* of present species.

**Bibliography.** Caziani & Protomastro (1991), Cintra & Yamashita (1990), Coelho (1987), Cory & Hellmayr (1924), Hayes (1995), Isler & Whitney (2002), do Nascimento *et al.* (2000), Naumburg (1939), Norez & Yzurieta (1983), Olmos (1993), Parker, Gentry *et al.* (1993), de la Peña (1988), Remsen *et al.* (1988), Ridgely & Tudor (1994), Sick (1993, 1997), Wetmore (1926), Willis & Oniki (1991), Zimmer (2003a).

# Genus *HERPSILOCHMUS* Cabanis, 1847

## 99. Spot-backed Antwren

### *Herpsilochmus dorsimaculatus*

**French:** Grisin strié

**German:** Fleckenmantel-Ameisenfänger

**Spanish:** Tiluchi Dorsimanchado

**Taxonomy.** *Herpsilochmus dorsimaculatus* Pelzeln, 1868, Marabitanas, Rio Negro, Amazonas, Brazil. Relationships with other species in genus unclear. Monotypic.

On following pages: 101. Bahia Antwren (*Herpsilochmus pileatus*); 102. Black-capped Antwren (*Herpsilochmus atricapillus*); 103. Creamy-bellied Antwren (*Herpsilochmus motacilloides*); 104. Ash-throated Antwren (*Herpsilochmus parkeri*); 105. Dugand's Antwren (*Herpsilochmus dugandi*); 106. Spot-tailed Antwren (*Herpsilochmus sticturus*); 107. Roraiman Antwren (*Herpsilochmus roraimae*).

**Distribution.** S Venezuela (W & S Bolívar, Amazonas), E Colombia (E Guainía, E Vaupés, E Caquetá) and NW Amazonian Brazil (E to R Trombetas in NW Pará).

**Descriptive notes.** 11-12 cm; 9-5-10-5 g. Long tail graduated. Male has black crown, long white supercilium, black eyestripe; dark grey upperparts with blackish patches, back feathers extensively edged white, outer scapulars black, edged white, concealed white interscapular patch; flight-feathers grey and black, edged white posteriorly, wing-coverts black, tipped white; tail black with white sides, tips white; underparts extensively white, tinged pale grey at sides and rear. Female differs from male in having buff on forehead, crown spotted white, buff on head side and breast. Subadult is like female except buffier. **Voice.** Loudsong a

somewhat short (e.g. 1-5 seconds) trilling rattle, intensity and pitch rise and then drop, final notes with overtones imparting harsh quality. Call a short (e.g. 0-1 second) downslurred plaintive note, repeated often but irregularly.

**Habitat.** Canopy and subcanopy of humid, lowland evergreen forest, to 600 m. In Venezuela (Amazonas), most often found in vine-rich canopy of seasonally flooded black-water forest (*igapó*); near Manaus (Brazil), restricted to canopy of tall *terra firme* forest or, less commonly, stunted *campina* woodland growing on white-sand soils.

**Food and Feeding.** Little published. Feeds on insects, including orthopterans and lepidopteran larvae; probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 15-30 m above ground, occasionally as low as 5 m in stunted sandy-soil woodland; sometimes alone, but more often with mixed-species flocks. Active but methodical forager, progressing by short hops, with intervening pauses of 1-2 seconds to scan foliage for prey. Concentrates activities in leafy outer branches and crowns of trees, particularly where overlapping branches and vine tangles form mats or sprays of vegetation; also hitches upwards along vine tangles and philodendrons (*Philodendron*) close to central trunks and major branches. Prey mostly perch-gleaned from live-leaf surfaces (mostly their tops) by quick stabs or short lunges; sometimes hover-gleans or flutter-gleans from underside of overhanging vegetation, or makes short sallies; seldom uses acrobatic manoeuvres such as hanging. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Orinoco-Negro White-sand Forests EBA. Fairly common throughout most of its range. Region inhabited by this species includes some large, protected areas, e.g. Yacapana and La Neblina National Parks, in Venezuela, and Pico da Neblina National Park, Waimiri-Atrorai Indigenous Reserve, Ducke Reserve and the BDFFP INPA forests near Manaus, in Brazil; also extensive intact habitat which, although not formally protected, appears to be at little risk of development in near future. This species considered highly sensitive to human disturbance.

**Bibliography.** Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Davis & O'Neill (1986), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Ridgely & Tudor (1994), Sick (1993), Stiles *et al.* (1995), Stotz (1990b), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Zimmer (2003a), Zimmer & Hilty (1997).

## 100. Caatinga Antwren

### *Herpsilochmus sellowi*

**French:** Grisin de Sellow

**German:** Caatingameisenfänger

**Spanish:** Tiluchi de Caatinga

**Taxonomy.** *Herpsilochmus sellowi* Whitney and Pacheco, 2000, Boa Nova, Bahia, Brazil.

Considered part of a clade that also includes *H. pileatus*, *H. atricapillus*, *H. motacilloides* and *H. parkeri*. Present species was long known under name of "*H. pileatus*", but recent study showing that population of SE Bahia is a distinct species also revealed that this name is actually applicable to the newly discovered form; a replacement scientific name for present species was thus required and supplied. Monotypic.

**Distribution.** NC & E Brazil (Maranhão E to Rio Grande do Norte and S to Bahia and extreme N Minas Gerais).

**Descriptive notes.** 10-5-11-5 cm; 7-8 g. Male has black crown and nape, white lores, long white to pale grey supercilium, short blackish postocular streak; upperparts grey, white interscapular patch usually with some black feather tips, blackish outer scapulars edged white; wings black, remiges edged white, coverts tipped white; graduated tail black, large white tips, outer feathers edged white; underparts white, tinged grey on breast, sides, flanks and crissum; underwing-coverts white. Distinguished from very similar *H. atricapillus* by shorter postocular streak, no black loreal spot, shorter narrower bill, other measurements. Female differs from male in having forehead and forecrown feathers edged dull buff (dappled effect), indistinct postocular streak, olive tinge above, supercilium and underparts tinged pale buff, underwing-coverts faintly tinged yellow. **Voice.** Loudsong a rapid series of similar notes (e.g. 40 notes, 2-8 seconds) mostly repeated at same pitch and pace, but rising and falling in pitch and amplitude at beginning and end. Rattle-like call a short (e.g. 6 notes) repetition of "wiip" notes; rattle short (e.g. 1 second), rising in pitch, usually introduced by slightly longer downslurred note.

**Habitat.** Middle and upper strata of *caatinga* woodland and scrub, *mata-de-cipó* vine forest, *caatinga-cerrado* ecotone; also *restinga* woodland in coastal Rio Grande do Norte; mostly at 300-900 m, but locally to 1100 m, and to near sea-level in N. Most numerous in semi-deciduous *caatinga* woodland and *mata-de-cipó* forest (semi-deciduous forest rich in vines and terrestrial

bromeliads at 700–1000 m Bahia); usually absent from more humid evergreen forest and arid lowland *caatinga* scrub.

**Food and Feeding.** Little published. Feeds on variety of insects, including orthopterans, particularly katydids (Tettigoniidae), also lepidopteran larvae, hemipterans and coleopterans; probably also on spiders. Stomach contents of two specimens from Pará contained orthopterans, beetles (Curculionidae) and hemipterans. Closely associated pair-members, individuals, or family groups forage mostly from 1–5 m (at shrubby borders and in dense *mata-de-cipó* woodland) to 12 m above ground. Alone, or with mixed-species flocks; often occurs in same flocks as syntopic *H. atricapillus*, then more often forages in open branches beneath canopy and in low, shrubby vegetation than latter; more locally, with *H. pectoralis* or *H. rufomarginatus*. Active but methodical forager, progressing steadily by short hops, separated by frequent pauses of 1–2 seconds to scan foliage, stems and branches. Typical foraging posture is horizontal, with the tail held slightly above plane of body and frequently lowered and then flicked upwards in shallow arc; both wings also regularly flicked, but not in exaggerated fashion. Prey usually perch-gleaned from live leaves or stems by reaching up, out or down and picking, or by short horizontal lunges; less frequently hangs head down to glean prey from tops of leaves, or makes short (15–30 cm) vertical sallies to underside of overhanging vegetation; seldom investigates dead leaves. Prey capture often accompanied by audible snap of the mandibles; most smaller items are immediately gulped; larger prey, such as many katydids, routinely beaten several times against a branch before being swallowed. Not known to follow army ants.

**Breeding.** Almost nothing known. One record of nearly fledged young in Feb.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout most of range. Known to occur in three protected areas: Chapada do Araripe National Forest (Ceará), Chapada Diamantina National Park (Bahia) and Cavernas do Peruáçu National Park (Minas Gerais). Most of its range, however, is without formal protection. Considered to be of medium sensitivity to human disturbance. Main problem is habitat loss and degradation. The dry forest, *caatinga* scrub and *mata-de-cipó* woodland favoured by this species are being rapidly cleared for cattle pastures and coffee plantations; even where not being cleared, they are being heavily exploited by local people for firewood and fence-post production, with grazing by cattle and goats preventing regeneration of most of the woody plants. The *mata-de-cipó* woodlands of Bahia, despite harbouring a high proportion of endemic and threatened species, remain unprotected; establishment of one or more reserves, preferably in Jequié-Boa Nova region, is a high priority. Until such reserves are set up, the future of this and other dry-forest endemics of the region will remain in question.

**Bibliography.** Anon (2001a), Gonzaga (2001), Isler & Whitney (2002), Kirwan *et al.* (2001), Olmos (1993), Pacheco & Parrini (2002), Parrini *et al.* (1999), Schubart *et al.* (1965), Snethlage (1928), Whitney *et al.* (2000), Zimmer (2003a).

## 101. Bahia Antwren

### *Herpsilochmus pileatus*

**French:** Grisin à coiffe noire **German:** Weißbrauen-Ameisenfänger **Spanish:** Tiluchi Pileado  
**Other common names:** White-browed/Pileated Antwren

**Taxonomy.** *Myiothera pileata* M. H. K. Lichtenstein, 1823, Trancoso, Bahia, Brazil.

Considered to be part of a clade that includes *H. sellowi*, *H. atricapillus* and *H. motacilloides*, all previously merged with present species, and *H. parkeri*. Present species only recently separated taxonomically; name “*H. pileatus*” long applied to *H. sellowi*, but studies in connection with taxonomic recognition of present species showed that the name was actually applicable to the newly discovered form: a replacement scientific name for the long-known form was thus required and supplied, “*H. sellowi*”. Monotypic.

**Distribution.** Coastal E Brazil in Bahia (S of Salvador).

**Descriptive notes.** 10.5–11 cm; two birds 8.5 g and 9.3 g. Male has black crown and nape, long white to pale grey supercilium, small blackish preocular spot, long blackish postocular streak; upperparts grey, white interscapular patch usually with some black feather tips, blackish outer scapulars edged white; wings black, remiges edged white, coverts tipped white; tail black, large white tips, outer feathers edged white; underparts white, washed grey, underwing-coverts white. Distinguished from extremely similar *H. atricapillus* by voice, in the hand by shorter, less graduated tail. Female differs from male in buffish forehead, extensively white-streaked crown, olive tinge above, faint ochraceous tinge below. Voice.

Loudsong a series of 4–7 accelerating notes followed by evenly paced notes, pitch and intensity rise and fall slightly at beginning and end (mean of 22 songs was 25 notes, 2–2 seconds). Calls include short note sounding like “greep”, and rather slow-paced rattle.

**Habitat.** Mid-storey and canopy of low-stature *restinga* woodland growing on sandy soils.

**Food and Feeding.** Nothing published. Feeds on insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly from 5 m up to the canopy, frequently lower in scrubby *restinga*, alone or with mixed-species flocks of other insectivores. Gleans prey mostly from foliage, but also from stems, vines and branches, mostly by reaches or short lunging stabs; sometimes by short sallies and hover-gleans.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted to a narrow band of *restinga* woodland and coastal forest in S Bahia, occurring only a short distance inland. Common in several localities. Relatively little of its habitats is currently accorded protected status: two of the more important protected sites are Monte Pascoal National Park and the Porto Seguro/Florestas Rio Doce SA Forest. Planned large-scale developments of beach resorts in S coastal Bahia could have a major negative impact on the conservation status of this species.

**Bibliography.** Collar & Andrew (1988), Collar *et al.* (1994), Cory & Hellmayr (1924), Davis & O'Neill (1986), Isler & Whitney (2002), Sick (1993), Stattersfield & Capper (2000), Whitney *et al.* (2000), Zimmer (2003a)

## 102. Black-capped Antwren

### *Herpsilochmus atricapillus*

**French:** Grisin mitré **German:** Schwarzscheitel-Ameisenfänger **Spanish:** Tiluchi Plomizo

**Taxonomy.** *Herpsilochmus atricapillus* Pelzel, 1868, Porto do Rio Paraná (probably = União), São Paulo, Brazil.

Until recently treated as conspecific with *H. sellowi* and *H. pileatus*; these three are considered to belong to a clade that also includes *H. motacilloides* and *H. parkeri*. Although no geographical races described, plumage and vocal variations exist across its extensive range; further research required. Monotypic.

**Distribution.** Extreme NW Argentina (Jujuy, Salta), W & E Bolivia (SW La Paz, and from Santa Cruz S along base of Andes), E Paraguay (E of R Paraguay) and SC & E Brazil (S Mato Grosso, Mato Grosso do Sul, extreme W Paraná and São Paulo N to Maranhão and Rio Grande do Norte).

**Descriptive notes.** 11–12 cm; 8–11 g. Both sexes vary in darkness and colour intensity of plumage. Male has black crown and nape, forehead with a few light feather tips, long white to pale grey supercilium, small blackish preocular spot, long blackish postocular streak; upperparts grey, white interscapular patch usually with some black feather tips, blackish outer scapulars edged white; wings black, remiges edged white, coverts tipped white; graduated tail black, large white tips, outer rectrices edged white; variably grey to pale grey below, belly white, underwing-coverts white. Distinguished from very similar *H. sellowi* by longer

postocular streak, black loreal spot, longer broader bill, other measurements. Female differs from male in buffish forehead, extensively white-streaked crown, olive tinge above, supercilium and underparts tinged pale buff, breast more ochraceous, underwing-coverts faintly tinged yellow. Voice. Loudsong 1–2 (rarely 3) distinct notes leading into rapid series (e.g. 24 notes, 2–3 seconds) rising and falling in pitch and slowing, initial notes at same pitch or higher than abrupt notes that follow; rattle usually a series of short but complex notes, more rarely a shorter series of simpler notes. Calls include abrupt, sharply downslurred note, and longer note that rises and falls in pitch.

**Habitat.** Middle and upper strata of deciduous, semi-deciduous and evergreen forest, also gallery forest, mostly below 800 m; present up to 1450 m along base of Andes. In NE Brazil, common in taller deciduous *caatinga* woodland, semi-deciduous *mata-de-cipó* forest, and humid evergreen forest.

**Food and Feeding.** Little published. Feeds on various insects, including especially lepidopteran larvae and orthopterans; probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 7–20 m above ground, often lower at forest edge, rarely down to 1 m, usually in leafier outer branches and crowns of trees and in central vine tangles. Alone or, more frequently, with mixed-species flocks; in parts of its range, often in same flocks as *H. sellowi*. Active but methodical forager, progressing by short hops, with pauses of up to 3 seconds to scan for prey; zigzags through branches and foliage with frequent changes of direction, often fluttering abruptly downwards for several metres in pursuit of dislodged prey; hitches from side to side with almost every hop, and usually thoroughly covers one tree before moving on to next. When foraging, usually holds its wings slightly drooped, and flicks them constantly; posture is horizontal, with tail held cocked 10–30 degrees above horizontal. Most prey gleaned from live leaves (particularly top surfaces), branches or vine surfaces, by reaches (out, up or down) or by short lunging stabs; often makes short (20–40 cm), upward-directed, diagonal sallies to take prey from underside of overhanging vegetation, then continues to another perch to consume prey; only rarely hangs down or performs other acrobatic manoeuvres in pursuit of prey. Occasionally probes suspended dead leaves, but more often ignores them. Small items consumed immediately; larger prey often beaten against thick branches several times before being swallowed. Not known to follow army ants.

**Breeding.** Nothing recorded. Family groups with juveniles fed by adults observed in Jan–Feb in Brazil (Ceará and Bahia).

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout most of its range. Considered to be of medium sensitivity to human disturbance. Range includes several protected areas, such as, in Brazil, Brasília, Araguaia, Chapada Diamantina and Serra do Cipó National Parks, Caraca National Park and Chapada do Araripe National Forest. In Brazil, particularly common in Jequié-Boa Nova region (Bahia) and in foothills and higher reaches of Serra de Baturité (Ceará), neither of which is formally protected, and both of which harbour a significant number of regional endemics and threatened species. Establishment of appropriate reserves in these areas would have the side benefit of protecting significant populations of present species. Its utilization of multiple habitat types renders it less vulnerable to disturbance than are locally syntopic species, such as *H. sellowi*, which are more restricted to dry-forest habitats.

**Bibliography.** Almeida *et al.* (1999), Braz & Cavalcanti (2001), Cory & Hellmayr (1924), Davis, S.E. (1993), Davis, T.J. & O'Neill (1986), Ferreira de Vasconcelos & Melo-Júnior (2001), Flores *et al.* (2001), Gonzaga (2001), Hayes (1995), Isler & Whitney (2002), Maldonado-Coelho & Marini (2000), do Nascimento *et al.* (2000), Naumburg (1939), Parker (2003a), Parker, Gentry *et al.* (1993), Parrini *et al.* (1999), Ridgely & Tudor (1994), Schubart *et al.* (1965), Schulenberg & Awbery (1997b), Sick (1993), Snethlage (1928), Stotz *et al.* (1996), Whitney & Álvarez (1998), Whitney *et al.* (2000), Zimmer (2003a).

## 103. Creamy-bellied Antwren

### *Herpsilochmus motacilloides*

**French:** Grisin motacilloide **German:** Fahlbauch-Ameisenfänger **Spanish:** Tiluchi Motaciloide  
**Other common names:** Yellow-bellied Antwren

**Taxonomy.** *Herpsilochmus motacilloides* Taczanowski, 1874, Maraynioc, Junin, Peru.

Formerly treated as a race of *H. pileatus*; considered with latter to be part of a clade that also includes *H. sellowi*, *H. atricapillus* and *H. parkeri*. Monotypic.

**Distribution.** E slope of Andes in Peru (Huánuco S to Cuzco).

**Descriptive notes.** 11–12 cm; 1 bird 12.5 g. Male has black crown and nape, forehead with a few light feather tips, long white to pale grey supercilium, black lores and long postocular streak; upperparts grey, white interscapular patch usually with some black-tipped feathers, blackish and grey outer scapulars edged white; wings black, remiges edged white, coverts tipped white; graduated tail black, large white tips, outer rectrices edged white; throat white, faintly spotted light grey, rest of underparts pale creamy yellow, sides washed grey. Distinguished from similar *H. atricapillus* by having entire loreal area from bill to eye black, spotted throat, yellowish underparts. Female differs from male in buffish forehead, extensively white-streaked crown, olive tinge above, pale yellow wing edgings. Voice. Loudsong 1–3 long flat notes followed by rapid series (e.g. 22 notes, 1–7 seconds) of abrupt notes, series descending in pitch. Call an abrupt, sharply downslurred note like that of *H. atricapillus*.

**Habitat.** Canopy and subcanopy of humid, montane evergreen forest and forest borders, at elevations of 1000-2500 m. Prefers dense, tall forest with heavy moss and epiphytic growth on trees.

**Food and Feeding.** Little known. Presumed to feed on various insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly in canopy and subcanopy, alone or, more often, with mixed-species flocks of other insectivores. Tends to concentrate foraging activities in leafy outer branches and crowns of trees. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Peruvian East Andean Foothills EBA. Fairly common but patchily distributed within its tiny range. Major threat to its conservation is deforestation; forest within the region remains relatively intact, especially above 900 m, but extensive areas are being logged and cleared for agriculture as human colonization increases. This species is considered to be highly sensitive to human disturbance.

**Bibliography.** Cory & Hellmayr (1924), Davis & O'Neill (1986), Isler & Whitney (2002), Mee *et al.* (2002), Ridgely & Tudor (1994), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (1932c).

## 104. Ash-throated Antwren

### *Herpsilochmus parkeri*

**French:** Grisin de Parker **German:** Graukehl-Ameisenfänger **Spanish:** Tiluchi de Parker  
**Other common names:** Parker's Antwren

**Taxonomy.** *Herpsilochmus parkeri* Davis and O'Neill, 1986, 15 km north-east of Jirillo, San Martín, Peru. Considered to be part of the *H. pileatus* clade, also including *H. sellowi*, *H. atricapillus* and *H. motacilloides*. Monotypic.

**Distribution.** E slope of Andes in NC Peru (San Martín).

**Descriptive notes.** 11.5-12.5 cm. Male has black crown and nape, forehead with a few light feather tips, long white to pale grey supercilium, black lores and long postocular streak; upperparts darkish grey, some feathers tipped black, white interscapular patch usually with some black tips, blackish outer scapulars edged white; wings black, remiges edged white, coverts tipped white; graduated tail black, large white tips, outer rectrices edged white; throat and underparts rather dark grey, belly whiter. Distinguished from similar *H. atricapillus* by being darker above and below, entire laral area from bill to eye black.

longer postocular streak. Female differs from male in extensively dark buff forehead, buff supercilium, pale buff throat, darker buff neck side and breast, buffish-olive sides, buffy grey flanks. Voice. Loudsong 1-3 short notes followed by rapid descending series (e.g. 21 notes, 2 seconds) of abrupt notes, similar to that of *H. motacilloides* except initial notes shorter and series not dropping so much in frequency. Call an abrupt, sharply downslurred note like that of *H. atricapillus*, repeated in groups of 2-3.

**Habitat.** Canopy and subcanopy of montane evergreen forest bordering savanna, at elevations of 1250-1450 m. Found in semi-stunted woodland with maximum canopy height 12 m, and with dense understorey and abundant epiphytes, on poor sandy soils; also in taller forest with closed canopy of 20-30 m.

**Food and Feeding.** Little known. Stomachs of five specimens contained variety of insects, primarily beetles (including Curculionidae, Coccinellidae), hemipterans and hymenopterans, with smaller numbers of homopterans, orthopterans, dermapterans, also one spider (probably Salticidae). Closely associated pair-members, individuals, or family groups forage mostly from mid-levels up to the canopy. Alone or, more often, with mixed-species flocks of other insectivores, including (most commonly) Ocellated Woodcreeper (*Xiphorhynchus ocellatus*), Buff-throated Foliage-gleaner (*Automolus ochrolaemus*), Streaked Xenops (*Xenops rutilans*), *Myrmotherula schisticolor*, and Buff-throated Tody-tyrant (*Hemitriccus rufularis*). E of Abra Patricia Pass, sometimes occurs in same flocks with *H. axillaris*. Not known to follow army ants.

**Breeding.** Virtually unknown. Birds with reduced gonads and worn plumage in Oct-Nov, suggesting that breeding just completed and post-breeding moult yet to begin; breeding season hypothesized to be during May-Sept dry season.

**Movements.** Presumed resident.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Andean Ridge-top Forests EBA. To date, known only from the low mountain range N of Moyobamba Valley (upper R Mayo), in San Martín, extending from the type locality, near Jesús del Monte, to above Afluente E of Abra Patricia pass (Pardo de Miguel); apparently not present at similar elevations S of the valley, where appears to be replaced by *H. axillaris*. Although fairly common near type locality, it has a tiny global range, and total population could number fewer than 1000 birds; given ongoing habitat destruction within its range, population can be assumed to be declining. Widespread destruction of mid-elevation Andean forests for cultivation of coca and coffee poses significant threat to many species of foothill bird. Lowland areas in R Huallaga Valley E of where present species occurs are almost entirely deforested, and clearance is gradually extending up the slopes of the mountain. The Afluente-Abra Patricia area, where the species has only recently been found, is under pressure following road improvements and resulting increased immigration and local increases in human population; many areas of potentially suitable habitat being cleared for timber extraction, agriculture and human settlement. Surveys designed to shed more light on the geographical distribution and population levels of this antwren are an immediate need, as is enforced protection of the type locality and the Alto Mayo Protected Forest.

## 105. Dugand's Antwren

### *Herpsilochmus dugandi*

**French:** Grisin de Dugand

**German:** Westamazonischer Ameisenfänger

**Spanish:** Tiluchi de Dugand

**Other common names:** Colombian Antwren

**Taxonomy.** *Herpsilochmus sticturus dugandi* Meyer de Schauensee, 1945, Belén, 600 feet [c. 180 m], Caquetá, Colombia.

Forms a superspecies with *H. sticturus*; formerly considered conspecific, but separated on basis of differences in female plumage and in calls. Monotypic.

**Distribution.** Extreme S & SE Colombia (base of Andes in Caquetá, and Leticia area in SE Amazonas), E Ecuador and NE Peru (N of R Maraón and R Amazon).

**Descriptive notes.** 10.5-11.5 cm; 9.3-11.3 g. Male has black crown and nape, long pale grey to white supercilium, black laral stripe and postocular stripe; dark grey upperparts variably patched black, white interscapular patch, black outer scapulars edged white; wings black, flight-feathers edged white posteriorly, coverts tipped white; short tail graduated, black, tips white, long white streak on inner web of central rectrices; throat and underparts pale grey, centre of belly white, underwing-coverts white. Differs from extremely similar *H. sticturus* in larger size. Female differs from male, and from *H. sticturus*, in rufous crown

and nape, buffy underparts, especially across breast. Voice. Loudsong an accelerating series of short notes, notes becoming more abrupt, like that of *H. sticturus* but perhaps flatter in pitch; differences remain to be studied. Call a clear, moderately long (0.2 seconds) whistle, pitch rising and falling.

**Habitat.** Canopy and subcanopy of humid, lowland evergreen forest, at 100-600 m, mostly below 450 m. Especially in vine tangles of both floodplain-forest and *terra firme* forest growing on rich soils.

**Food and Feeding.** Little published. Feeds on insects, including lepidopteran larvae, orthopterans (Tettigoniidae) and preying mantises (Mantidae); probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 20-40 m above ground, sometimes alone, usually with mixed-species flocks of other insectivores. Active but methodical forager, progressing by short hops, with frequent pauses of 1-4 seconds to scan for prey; on zigzag and somewhat erratic path, with numerous abrupt changes of direction and frequent retracing of route, often spending several minutes in a small area before moving on; posture horizontal, habitually flicks both wings shallowly as it forages. Forages mostly in leafy outer branches and crowns of trees, where it perch-gleans most prey from upper and lower surfaces of live leaves and from stems and branches, mostly by reaching out, up or down with quick bill-stabbing motions, or by short horizontal lunges; also makes short (less than 40 cm) fluttering sallies or hover-gleans, usually to overhanging foliage, but rarely hangs or utilizes other acrobatic manoeuvres. Seldom investigates suspended arboreal dead leaves. Smaller prey immediately swallowed, but larger items are bashed repeatedly against branches before swallowing; wipes bill on branch after consuming prey. Not known to follow army ants.

**Breeding.** Nest found in Jul in Peru (near Quebrada Susuari; details previously unpublished): a small pendent cup or bag, exterior constructed from bright green moss, with several wide stems of lichens around bottom, placed 35 m off ground in fork of thin branch in densely leafed section of tree; male seen to carry food to nest, and remain to brood young.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common over much of its range; until recently considered rare, but now known to have been previously overlooked in many areas. Range includes, in Ecuador, the large Yasuni National Park, as well as several privately protected reserves centred around ecotourist lodges (e.g. La Selva, Sacha, Cuyabeno and Kapawi Lodges), Tiputini Biodiversity Station and Jatun Sacha; in Peru, species occurs in forest around Explornapo and ACEER lodges. Range also encompasses extensive areas of intact habitat which, although not formally protected, seem to be at little immediate risk of development. Considered to be highly sensitive to human disturbance.

**Bibliography.** Álvarez (1994), Davis & O'Neill (1986), Hilty & Brown (1986), Isler & Whitney (2002), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Stotz *et al.* (1996), Whitney (2003b), Whitney & Álvarez (1998), Zimmer (2003a).

## 106. Spot-tailed Antwren

### *Herpsilochmus sticturus*

**French:** Grisin givré

**German:** Salvinameisenfänger

**Spanish:** Tiluchi Colipunteado

**Taxonomy.** *Herpsilochmus sticturus* Salvin, 1885, Bartica and Kamacusa, Guyana.

Forms a superspecies with *H. dugandi* and formerly considered conspecific, but separated on basis of differences in female plumage and in calls. Monotypic.

**Distribution.** E Venezuela (Bolívar E of R Caura and S of R Orinoco), the Guianas and NE Amazonian Brazil (E of R Trombetas).

**Descriptive notes.** 9.5-10.5 cm; 8-9 g. Male has black crown and nape, long pale grey to white supercilium, black laral stripe and postocular stripe; dark grey upperparts with variable black patches, white interscapular patch, black outer scapulars edged white; wings black, flight-feathers edged white posteriorly, coverts tipped white; short tail graduated, black, tips white, long white streak on inner webs of central rectrices; throat and underparts grey, centre of belly white, underwing-coverts white. Distinguished from extremely similar *H. dugandi* by smaller size. Female differs from male in long rufous-cinnamon streaks on crown, buff-tinged wing edgings, paler throat and underparts, underparts tinged buff. Voice.

Loudsong a series of short notes (e.g. 26 notes, 2-8 seconds) that accelerate and become more abrupt, initially rises in pitch and then flattens out, pitch and intensity drop at end. Calls include sharply downslurred "chut" repeated in groups of 2-3, and abrupt (e.g. 0-1 second) muffled whistle, mostly upslurred.

**Habitat.** Canopy and subcanopy of humid lowland evergreen forest, from near sea-level to 550 m. In general, possibly most frequent in gallery and other seasonally flooded forest and in forest growing on nutrient-poor quartzitic or podzolic soils. In Guyana, Surinam and Brazil (Amapá), appears to occur more often in lowland forest near water than does *H. stictocephalus*, but ecological distinctions between the two poorly known; in Venezuela (Bolívar), may occupy slightly drier forest (on poorer soils) than does that species. Often found in vine tangles.

**Food and Feeding.** Little published. Feeds on variety of arthropods; stomachs of birds from Surinam contained beetles (Coleoptera), hemipterans and spiders. Closely associated pair-members, individuals, or family groups forage mostly 15-30 m above ground, sometimes alone, but more often with mixed-species flocks of other insectivores; often found in same mixed flocks as *H. stictocephalus*, and in French Guiana appears to forage closer to ground than latter. Active forager, progressing by short hops, separated by frequent pauses of 1-2 seconds to scan for prey; hitches from side to side, with frequent changes of direction. Most prey perch-gleaned from leaf, stem and vine surfaces, by reaching out, up or down with quick stabbing motions of the bill. Not known to follow army ants.

**Breeding.** Almost unknown. Young fledged in Oct in French Guiana.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout its range; only recently found to be present in Amapá (Serra do Navio). Occurs in several large protected areas, e.g. Canaima and Jaua-Sarisariñama National Parks and Caura Forest Reserve, in Venezuela, and Raleigh Falls-Voltzberg National Park, in Surinam; also, particularly in the Guianas, occurs in extensive areas of intact habitat which are not formally protected but appear to be at little risk of development in near future. Considered to be highly sensitive to human disturbance.

**Bibliography** Cory & Hellmayr (1924), Davis & O'Neill (1986), Haverschmidt & Mees (1994), Hellmayr (1929b), Hilty (2003a), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Parker, Foster *et al.* (1993), Ridgely & Tudor (1994), Robbins (2003a), Sick (1993), Stotz *et al.* (1996), Thiollay (1994), Tostain *et al.* (1992), Whitney (2003a), Whitney & Alvarez (1998), Zimmer (2003a).

## 107. Roraiman Antwren

### *Herpsilochmus roraimae*

**French:** Grisin du Roraima    **German:** Tepuiameisenfänger    **Spanish:** Tiluchi del Roraima

**Taxonomy.** *Herpsilochmus roraimae* Hellmayr, 1903, Mount Roraima, 3500 feet [c. 1060 m], Bolívar, Venezuela.

Relationships unclear; possibly closest to *H. dorsimaculatus*. Two subspecies recognized.

#### **Subspecies and Distribution.**

*H. r. kathleenae* Phelps, Jr. & Dickerman, 1980 - tepuis region of SW Venezuela (W & S Bolívar, Amazonas) and adjacent Brazil (extreme N Amazonas).

*H. r. roraimae* Hellmayr, 1903 - tepuis region of SE Venezuela (E Bolívar E of R Caroni), adjacent Brazil (extreme N Roraima) and WC Guyana.

**Descriptive notes.** 12-13 cm. Longer tail than all related species. Male has black crown and nape, long pale grey to white supercilium, black loreal stripe and postocular stripe; dark grey upperparts with variable black patches, many white feather edges, white interscapular patch, black outer

scapulars edged white; wings black, flight-feathers edged white posteriorly, coverts tipped white; tail black, tips white, outer feathers edged white, longer central rectrices with multiple white spots along both webs; throat and underparts grey, with central belly white, underwing-coverts white. Female differs from male in white crown spots, buff-tinged neck side, light buff breast and sides, smaller tail spots. Race *kathleenae* differs from nominate in female having greyer upperparts, pale grey rather than light buff breast and sides. **VOICE.** Loudsong an uncountable series (e.g. 20 notes, 2-1 seconds) of strident, sharply downslurred

notes, flat initially, that decelerates and drops in pitch and intensity at end. Calls include very abrupt "chup" notes, given singly, in pairs and in short series and repeated rapidly, and slightly longer, downslurred "tewp", also irregularly or in rapid, rattle-like series.

**Habitat.** Canopy and subcanopy of humid to wet, evergreen forest and forest borders, at 700-2000 m. Occupies tall forest growing on richer soils on lower and mid-slopes of tepuis; also stunted forest dominated by melastome (*Melastoma*) on poorer soils near the tops, and occurs regularly at ecotones between latter habitat and brushy savanna at higher elevations.

**Food and Feeding.** Little published. Feeds on variety of insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly in leafy outer branches and crowns of canopy trees, to 30 m in tall forest, but as low as 3 m in crowns of shrubs and small saplings in stunted melastome forest. Sometimes alone, more often with mixed-species flocks of other insectivores, especially redstarts (*Myioborus*) and tanagers (Thraupidae). Active forager, working methodically through leafy branches, progressing by short hops, with pauses of 1-2 seconds to scan foliage; also hitches upwards, turning from side to side, along hanging vines in interior portions of canopy. Prey mostly perch-gleaned from live-leaf surfaces (more often tops), sometimes by short, lunging stabs; also sometimes flutter-gleans or hover-gleans from underside of overhanging vegetation and makes occasional short sallies, but seldom employs truly acrobatic manoeuvres in pursuit of prey. Occasionally forages in masses of dead leaves, pulling and picking at curled surfaces. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tepuis EBA. Locally fairly common throughout its small range. This region includes several large protected areas, such as Canaima, Duida, La Neblina and Jaua-Sarisariñama National Parks and the Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, and Pico da Neblina National Park, in Brazil. Recently, all lands over 800 m and lying S of R Orinoco in Venezuela were declared national monuments, effectively affording all of the tepuis and, hence, most of the range of this species some measure of protection. These remain for the most part "paper reserves", without effective, on-the-ground protection. Species is considered to be highly sensitivity to human disturbance; amount of intact habitat, however, is vast, and current level of threat from human disturbance is low. Major threats to this ecosystem are from human-caused fires, and illegal gold-mining activities.

# 108. Yellow-breasted Antwren

## *Herpsilochmus axillaris*

**French:** Grisin à poitrine jaune

**Spanish:** Tiluchi Pechiamarillo

**German:** Gelbkehl-Ameisenfänger

**Other common names:** Yellow-margined Antwren

**Taxonomy.** *Thamnophilus axillaris* Tschudi, 1844, Peru.

Relationships with other species in genus unclear. Plumage distinctions between races *aequatorialis* and *puncticeps* poorly understood. Four subspecies recognized.

### Subspecies and Distribution.

*H. a. senex* Bond & Meyer de Schauensee, 1940 - W & C Andes in W Colombia (Riseralda S to Cauca).  
*H. a. aequatorialis* Taczanowski & Berlepsch, 1885 - E slope of Andes in E Ecuador and N Peru (N of R Maraón).

*H. a. puncticeps* Taczanowski, 1882 - EC Peru S of R Maraón (S to Junin).

*H. a. axillaris* (Tschudi, 1844) - E slope in SE Peru (Cuzco E to Puno).

**Descriptive notes.** 11-12 cm; 10-13 g. Male has black crown spotted white, broken whitish supercilium; side of head mottled blackish and olive-yellow; upperparts olive-grey; flight-feathers very dark grey, tinged olive, edged yellowish-olive, wing-coverts black, tipped and edged white with faint yellow tinge; tail graduated, very dark grey, inner feathers tipped and partially edged white, outer feathers mostly white; throat and underparts pale yellowish-olive, belly centre yellow. Female differs from male in cinnamon-rufous forehead and crown, more olive-buff upperparts, darker olive underparts except belly centre. Race *senex* is paler

above and below, white spots confined more to centre of crown, throat and uppermost breast greyish-white, sharply separated from yellow below; *puncticeps* has upperparts greyer, tinged olive, less white on outer tail feathers, female crown dark olive-grey, tinged cinnamon-rufous; *aequatorialis* is similar to last, white spots on crown restricted to centre, mostly pale yellow below, sides washed olive. **Voice.** Loudsong a rattle-like trill of dry notes (e.g. 30 notes, 2-2 seconds), flat, then decreasing in pitch and intensity while accelerating slightly. Call a short (e.g. 0-2 seconds) downslurred whistle.

**Habitat.** Subcanopy of humid montane evergreen forest and forest borders, at 800-1900 m; 500-1500 m in SE Peru.

**Food and Feeding.** Feeds on variety of insects, probably also spiders. Forages in pairs, with partners closely associated, and in family groups, rarely singly, mostly at mid-heights at forest edge; often in crowns of subcanopy trees, commonly in mid-storey vine tangles, occasionally in crowns of bamboo, sometimes ascending to canopy of tallest trees. Almost always with mixed-species flocks of other insectivores and frugivores. Active forager, progressing by short hops, with frequent deliberate pauses of 1-2 seconds to scan for prey; concentrates foraging in leaves and twigs of leafier outer branches and crowns of trees. Most prey perch-gleaned by reaching out, up or down with quick bill-stabbing motions, or by short horizontal lunges; occasionally hover-gleans from leaves. Not known to follow army ants.

**Breeding.** Almost nothing known. Record of female ready to lay egg in Mar in Peru.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Status not well known; generally considered uncommon and somewhat patchily distributed throughout its range. Region occupied by this species includes a few large protected areas, e.g. Podocarpus National Park and Sumaco Protection Forest, in Ecuador, and Manu National Park and Biosphere Reserve, in Peru. Considered to be of high sensitivity to human disturbance. As with other species restricted to lower Andean slopes, primary threat virtually throughout its range is accelerating deforestation of lower montane forest for human colonization, logging, and agriculture.

**Bibliography.** Cory & Hellmayr (1924), Davis & O'Neill (1986), Hilty (1997), Hilty & Brown (1986), Isler & Whitney (2002), Parker (2003a), Parker & Parker (1982), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Taczanowski (1884), Whitney & Álvarez (1998), Zimmer, J.T. (1932c), Zimmer, K.J. (2003a).

# 109. Ancient Antwren

## *Herpsilochmus gentryi*

**French:** Grisin de Gentry

**German:** Gentrys Ameisenfänger

**Spanish:** Tiluchi Antiguo

**Taxonomy.** *Herpsilochmus gentryi* Whitney & Álvarez, 1998, P. J. Lores, Loreto, Peru.

Appears to form a superspecies with *H. stictocephalus*; similarity of vocalizations have suggested to some that both are closely related to the *H. pileatus* group. Monotypic.

**Distribution.** Extreme E Ecuador (SE Pastaza) and N Peru (Loreto W of R Napo and N of R Maraón).

**Descriptive notes.** 10-11 cm; 10-2-11 g. Male has black crown and nape, long yellowish supercilium, black loreal stripe and broad postocular stripe; dark grey upperparts with variable black patches, white interscapular patch, black outer scapulars edged white; wings black, flight-feathers edged white posteriorly, coverts tipped white; tail graduated, black, tips white, long white streak on inner webs of central rectrices; head side, throat and underparts yellowish, tinged olive on sides and flanks. Female differs from male in small orangish spots on forehead, becoming yellowish to white spots on crown, darker below, especially on breast and sides. **Voice.** Loudsong a moderately long series (e.g. 15 notes, 2-1 seconds) that increases and then decreases in pitch and intensity, decelerates throughout, only final notes countable; female song similar but shorter. Calls include abrupt "chup", longer "tink", and a rattle-like series of abrupt notes given in randomly interrupted stream.

**Habitat.** Canopy and subcanopy of humid tropical lowland evergreen forest, to 200 m. Apparently restricted to two types of lowland *terra firme* forest growing on nutrient-poor podzolic and quartzitic soils; in Peru, these known respectively as *irapayal* (canopy height over 40 m, understory domi-

nated by *Lepidocaryum tenue* palms 2-3 m tall) and *varillal* (more stunted forest on purer white-sand soils). In Ecuador, occupies tall *terra firme* forest on the highest, driest ridgetops.

**Food and Feeding.** Little known. Feeds on insects, perhaps particularly adult and larval lepidopterans; probably also on spiders. Closely associated pair-members, individuals, or family groups forage in uppermost strata of forest, mostly 15-40 m above ground, usually with mixed-species flocks. Active but methodical forager, progressing by short hops and flutters, with frequent pauses of 1-2 seconds to scan for prey; often spends several minutes in a given tree, deliberately retracing its routes and frequently changing course; flicks wings shallowly and rapidly, but without obvious tail movements. Foraging activities concentrated in leafy outer branches and crowns (periphery) of trees, where most prey perch-gleaned from live leaves and slender branches by reaching out, up or down with quick bill-stabbing motions, or by short horizontal lunges; occasionally flutters down abruptly in pursuit of flushed prey. Not recorded to investigate dead leaves. Not known to follow army ants.

**Breeding.** Little known. Moulting condition and skull ossification of two juveniles indicated fledging in Feb-Mar, as did family groups with juveniles observed in mid-Apr.

**Movements.** Presumably resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Only recently discovered, and still poorly known; appears to be locally common within its specialized habitat. Primary threat is to habitat type itself, which is patchily distributed in Amazonia and considered particularly vulnerable to perturbation. Recent opening of a paved road through sandy-soil habitats out of Iquitos, in Peru, has encouraged an explosion of human colonization, leading to many of the *varillales* on which this species is largely dependent being clear-cut for a variety of uses; such development, if unchecked, could result in endangerment of not only this but also several other localized species, including *Pernostola arenarum*. Recent creation of Allpahuayo-Mishana Reserved Zone, encompassing c. 27,000 ha of *varillales*, *irapayales* and other forest and palm-swamp habitats, is a critical first step in protection of the highly endemic flora and fauna of the region's sandy-soil forests; continued protection of the integrity of this reserve and prevention of illegal extractive exploitation equally crucial. In Ecuador, this species is known only from vicinity of Kapawi Lodge and surrounding Kapawi Ecological Reserve, which seem secure from habitat destruction. Efforts should be made to locate any additional population centres for this species, and to gain better knowledge of its distribution and population levels.

**Bibliography.** Anon. (1998f, 1998g, 2002b), Isler & Whitney (2002), Ridgely & Greenfield (2001), Stattersfield & Capper (2000), Whitney & Álvarez (1998).

# 110. Todd's Antwren

## *Herpsilochmus stictocephalus*

**French:** Grisin de Todd

**German:** Toddameisenfänger

**Spanish:** Tiluchi de Todd

**Taxonomy.** *Herpsilochmus stictocephalus* Todd, 1927, Saut Tamanor, French Guiana.

Appears to form a superspecies with *H. gentryi*; similarity of vocalizations have suggested to some that both are closely related to the *H. pileatus* group. Monotypic.

**Distribution.** E Venezuela (E Bolívar E of R Caroni), the Guianas and extreme NE Amazonian Brazil (NE Pará and Amapá).

**Descriptive notes.** 10-11 cm; 8-9.5 g. Male has black top of head, forehead with short white streaks, long white supercilium, black loreal spot and long postocular stripe; light grey upperparts with few small black patches, white interscapular patch, black outer scapulars edged white; wings black, flight-feathers edged white posteriorly, coverts broadly tipped white; tail graduated, black, tips white, outer feathers edged white, white spots and short white streak on inner webs of central rectrices; throat white, underparts lightly washed pale grey, sides slightly darker, underwing-coverts white. Female differs from male in white crown spots,

tinged buff on forehead, light buff breast and sides. **Voice.** Loudsong a moderately long series (13 notes, 2 seconds) similar to that of *H. gentryi*, except initial notes delivered at slower pace (most notes can be counted) and change in pitch over length of song is greater; that of female shorter. Calls include abrupt, downslurred "tup" and even more abrupt, vibrant "chit".

**Habitat.** Canopy and subcanopy of humid tropical lowland and foothill evergreen forest, to 700 m. Compared with *H. sticturus*, appears to be more concentrated in tall, humid forest on better soils, and ranges higher into foothills; rare or absent in savanna forest and seasonally flooded forest where that species is often found; ecological distinctions between them, however, poorly documented.

**Food and Feeding.** Little published. Feeds on various arthropods; stomach samples from Surinam included beetles (Coleoptera), hemipterans and spiders. Closely associated pair-members, individuals, or family groups forage mostly 20-40 m above ground, occasionally lower at forest edge. Alone, or with mixed-species flocks of other insectivores; in some locations found in same flocks as *H. sticturus*, tending to forage at higher levels than latter in French Guiana. Forages mostly in leafy outer branches and crowns of trees and in vine tangles and masses of philodendrons (*Philodendron*) along major trunks. Active but methodical forager, progressing by short hops separated by frequent pauses of 1-2 seconds to scan for prey; hitches from side to side, often in zigzag progression with frequent changes of direction. Most prey perch-gleaned from all surfaces of live leaves, stems and vines, by reaching out, up or down with quick stabbing motions of the bill, or by short horizontal lunges; not particularly acrobatic. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Status not well known; generally considered uncommon throughout most of its range. Considered to be of high sensitivity to human disturbance. Range occupied includes some protected areas, e.g. Canaima National Park and Imataca Forest Reserve and El Dorado, in Venezuela, and Brownsberg Nature Park, in Surinam; also extensive areas of intact habitat within, while not formally protected, appear to be at little risk of development in near future.

**Bibliography.** Davis & O'Neill (1986), Haverschmidt & Mees (1994), Hellmayr (1929b), Hilty (2003a), Isler & Whitney (2002), Ridgely & Tudor (1994), Robbins (2003a), Sick (1993), Stotz *et al.* (1996), Thiollay (1994), Jostain *et al.* (1992), Whitney (2003a), Whitney & Álvarez (1998), Zimmer (2003a).

## 111. Large-billed Antwren

### *Herpsilochmus longirostris*

**French:** Grisin à grand bec **German:** Fleckenbrust-Ameisenfänger **Spanish:** Tiluchi Piquilargo

**Taxonomy.** *Herpsilochmus longirostris* Pelzel, 1868. Cuiabá, Mato Grosso, Brazil. Thought to be most closely related to *H. pectoralis* on basis of plumage and distribution, although vocalizations not closely similar. Monotypic.

**Distribution.** Bolivia (locally in N Beni, N Santa Cruz) and SC & NE Brazil (C Mato Grosso E to Tocantins and Goiás, extending NE locally to S Ceará and S Piauí, and S to W Paraná and W São Paulo).

**Descriptive notes.** 12-13 cm; 12-14 g. Male has black crown, long whitish supercilium, blackish lores edged white, thin black stripe behind eye; upperparts grey, interscapular patch black and white (visible), uppertail-coverts black, tipped white; wings black, remiges edged white posteriorly, coverts broadly tipped white; outer tail feathers white, inner feathers black with white tips, central rectrix edged white; underparts white, with tiny black spots on side of breast, greyish sides and flanks; underwing-coverts white. Distinguished from *H. pectoralis* by larger size, no black breast patch. Female differs from male in rufous-cinnamon crown, cinnamon-tinged ear-coverts and upperparts, cinnamon neck, throat and underparts, becoming paler posteriorly, cinnamon-tinged underwing-coverts. Subadult male plumage thought to persist for some time, resembles that of female. **Voice.** Loudsong (e.g. 15 notes, 2-2 seconds) two-parted, with short abrupt notes replaced about half-way through by 4-5 longer notes, final notes delivered more slowly and countable, overall pitch and intensity rise and fall. Calls include distinct, rapidly delivered triplet in which notes become shorter and drop in pitch; also abrupt downsturred note, typical of genus.

**Habitat.** Understorey to canopy of gallery forest, deciduous and semi-deciduous forest, and palm groves, at 150-1100 m; in Bolivia, often found in small forest patches surrounded by *cerrado* and open fields.

**Food and Feeding.** Little published. Feeds on insects, including adult and larval lepidopterans and orthopterans; probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 1.5-10 m above ground, less commonly to 15 m; alone, or with mixed-species flocks of other insectivores. Active but methodical forager, progressing by short hops, with frequent pauses of 0.5-3 seconds to scan for prey; tends to cover a tree thoroughly before moving on, following zigzag course with frequent changes of direction and retracing of route; foraging posture generally horizontal, with tail held nearly level with plane of body, and wings flicked shallowly and constantly. Concentrates in leafier portions of subcanopy and understorey, but also spends considerable time working along bare woody vines. Prey usually perch-gleaned from both surfaces of live leaves, from leaf petioles, and from vine and branch surfaces, by reaching out, up or down with quick bill-stabbing motions, or by short lunging stabs; regularly makes short (15-30 cm) diagonal sallies to underside of vegetation; also flutters abruptly downwards to pursue dislodged prey (particularly Orthopterans and moths). Seldom investigates suspended dead leaves, but will, on occasion, drop to the ground to take prey from surface of leaf litter. Smaller items consumed immediately; larger prey bashed repeatedly on branches before being swallowed; almost invariably wipes the bill vigorously on branch after each prey capture. Not known to follow army ants.

**Breeding.** Not well known. In Brazil, gonadal condition of birds in Paraná and S Mato Grosso suggests breeding in Sept-Dec, at beginning of rainy season; pair carrying nesting material in Sept in Goiás. One described nest was a small cup 6 cm in total length, 5 cm wide, 8 cm in height, with egg-chamber 6 cm deep, composed of several leaves (especially of the bamboo *Guadua spinosissima*), spades of an unidentified grass, filaments of the fungus *Marasmius*, kapok and radicles, placed 1-5 m above ground and either set in or hanging from fork concealed among branches of lauraceous tree *Ocotea suaveolens*; said to be similar to nests of *Thamophilus* species.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common over most of its range; in Brazil, particularly common in appropriate habitat along entire length of the Transpantaneira road in Mato Grosso. Range includes several large protected areas, e.g. Das Emas, Brasília, Chapada dos Guimarães and Pantanal Mato-grossense National Parks and Serra das Araras Ecological Station, in Brazil, and Noel Kempff Mercado National Park, in Bolivia. Considered to be of medium sensitivity to human disturbance.

**Bibliography.** Bates *et al.* (1992), Cintra & Yamashita (1990), Cory & Hellmayr (1924), Davis & O'Neill (1986), Isler & Whitney (2002), Marini, Motta-Júnior *et al.* (1997), Marini, Pereira *et al.* (1997), do Nascimento *et al.* (2000), Parker (2003a, 2003b), Parker & Rocha (1991), Ridgely & Tudor (1994), Sick (1955, 1993, 1997), Stotz *et al.* (1996), Straube *et al.* (1992), Whitney *et al.* (2000), Zimmer (2003a).

## 112. Pectoral Antwren

### *Herpsilochmus pectoralis*

**French:** Grisin à collier **German:** Brustband-Ameisenfänger **Spanish:** Tiluchi Pectoral

**Taxonomy.** *Herpsilochmus pectoralis* P. L. Sclater, 1857, no locality = Bahia, Brazil. Thought to be most closely related to *H. longirostris* on basis of plumage and distribution, although vocalizations not closely similar. Monotypic.

**Distribution.** NE Brazil locally from NE Maranhão E to Rio Grande do Norte, S to Sergipe and NE Bahia.

**Descriptive notes.** 11-12 cm. Male has black crown spotted white around edges, long whitish supercilium, blackish lores edged white, narrow black stripe behind eye; upperparts grey, interscapular patch black and white (visible), uppertail-coverts black, tipped white; wings black, remiges edged white posteriorly, coverts broadly tipped white; outer tail feathers white, inner feathers black with white tips, central rectrix edged white; underparts white, black patch on breast, grey sides and flanks; underwing-coverts white. Distinguished from *H. longirostris* by black breast patch, smaller size. Female differs from male in rufous crown,

brownish-olive upperparts, buffish flight-feather edges, buff neck side and underparts, brightest on breast. **Voice.** Loudsong a moderately long (e.g. 2 seconds) complex series that sounds two-parted though pace near-constant, begins with long "caa" notes that shorten while first rising and then dropping in pitch and intensity, then lower-pitched harmonic becomes more dominant and gradually rises in pitch and intensity while notes continue to shorten. Call a flat "caa", like initial note of loudsong.

**Habitat.** Recorded from gallery forest and deciduous forest in Maranhão, wooded *restinga* in Rio Grande do Norte, and tall *caatinga* woodland and closed old secondary forest in Bahia; from near sea-level to 850 m. Historically, recorded from dry palm woodland on banks of middle R Itapicuru (Maranhão). In recent surveys W of Jeremoabo (Bahia), found in tall *caatinga* woodland, largely deciduous but with scattered broadleaf evergreen trees taller than 15 m, and with dense understorey and abundant terrestrial bromeliads, cacti and other stem-succulents (possibly *Euphorbia*). Utilizes all levels of forest, from understorey to canopy.

**Food and Feeding.** Little published. Feeds on insects, including lepidopteran larvae and orthopterans, e.g. katydids (Tettigoniidae); probably also takes spiders. Closely associated pair-members, individuals, or family groups forage mostly 2.5-7 m above ground, sometimes to 12 m, rarely dropping down to ground level; usually concentrating in crowns of understorey trees and shrubs and in mid-levels and subcanopy of taller emergent trees. Alone, or often with mixed-species flocks of other insectivores. Active but methodical forager, progressing by short hops, with frequent pauses of 1-5 seconds to scan for prey; hitches from side to side as it sets an erratic course with frequent directional changes and retracing of routes, frequently spending several minutes in a single tree before moving on; works all zones of trees, inner portions as well as peripheral branches, and bare branches as well as densely leaved ones; foraging posture generally horizontal, and wings flicked shallowly and constantly, tail occasionally lowered slowly and then flicked quickly upwards. Most prey perch-gleaned from live foliage (both tops and undersides of leaves in nearly equal proportions) and bare vine and branch surfaces, by reaching out, up or down with quick stabbing motions of the bill, or by short horizontal lunges; also frequently gleans from bark crevices of trees and from various stem-succulents (cacti, *Euphorbia*); often makes short (15-30 cm) fluttering sallies to undersides of leaves and branches, and sometimes flutters down abruptly to pursue dislodged prey (particularly katydids). Prey capture usually accompanied by audible snap of mandibles; smaller items consumed immediately, larger prey bashed repeatedly against branches before swallowing. Not known to follow army ants.

**Breeding.** Little known. Two females with well-developed ovaries in late Aug in Bahia, and family party with independent immatures recorded in late Sept.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Has highly fragmented range; currently known from only a few scattered sites, only one of which, the small Itabaiana Reserve, in Sergipe, is formally protected. The taller *caatinga* and deciduous woodlands in which this species is found are rapidly being destroyed. It persists at several sites in Bahia which are under fairly intense grazing pressure by cattle and goats; areas near Jeremoabo with reasonably dense mid-storey and understorey vegetation (containing thickets with interlocking branches) still supported reasonable densities of this antwren as recently as Jan 2000, despite being dissected by numerous livestock trails. More immediate threat is rampant cutting of understorey vegetation for firewood and for charcoal production; nearby areas which harboured territories in 1996 and 1997 have subsequently suffered extensive clearance of understorey vegetation and no longer support the species. Population in the *restinga* woodlands of Rio Grande do Norte may be important, but remains to be censused. Systematic surveys needed in order to determine true extent of the species' range and population, as well as the best locations for creation of multiple small reserves.

**Bibliography.** Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Cory & Hellmayr (1924), Davis & O'Neill (1986), Hellmayr (1929b), Isler & Whitney (2002), Parrini *et al.* (1999), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Teixeira, Otcho *et al.* (1993), Wege & Long (1995), Zimmer (2003a).

## 113. Rufous-winged Antwren

### *Herpsilochmus rufimarginatus*

**French:** Grisin à ailes rousses **German:** Rotschwungen-Ameisenfänger **Spanish:** Tiluchi Alirrufo

**Taxonomy.** *Myiothera rufimarginata* Temminck, 1822, Rio de Janeiro, Brazil.

Relationships with other members of genus unclear. Differences in morphology and vocalizations suggest that more than one species may be involved; re-examination required. Four subspecies currently recognized.

**Subspecies and Distribution.**

*H. r. exiguus* Nelson, 1912 - E Panama (Darién), NW Colombia (Córdoba, Bolívar) and W Ecuador (Esmeraldas, Los Ríos).

*H. r. frater* P. L. Sclater & Salvin, 1880 - N & S Colombia (base of Andes in La Guajira, Boyacá, Meta, Putumayo) S to E Peru and N Bolivia (Pando and La Paz E to Santa Cruz), also N & S Venezuela (Zulia E to Monagas, and Bolívar and N Amazonas), extreme S Guyana, and extreme N and SC Amazonian Brazil (N Roraima, and from S Pará and W Maranhão SW to Rondônia and N Mato Grosso).

*H. r. scapularis* (Wied, 1831) - E Brazil (coastal Paraíba S to Alagoas, and in E Bahia, E Minas Gerais and Espírito Santo).

*H. r. rufimarginatus* (Temminck, 1822) - E Paraguay (E of R Paraguay), extreme NE Argentina (Misiones) and SE Brazil (São Paulo, Rio de Janeiro, Paraná, NE Santa Catarina).

**Descriptive notes.** 10-12.5 cm; 10-12.5 g. Male nominate race has black crown, long whitish supercilium, black loreal streak and long postocular streak; side of head mottled black and pale yellow or white; upperparts olive-grey, variably patched black, outer scapulars edged white, uppertail-coverts yellow; flight-feathers dark grey, tinged olive-brown, edged bright cinnamon-rufous, coverts black, tipped white; graduated tail dark grey, tipped white, outer feathers white;

throat and underparts light yellow, sides tinged olive; underwing-coverts pale yellow. Female differs from male mainly in rufous forehead, rufous-brown crown, olive-brown back. Race *frater* is like nominate but has greyer back with more black patches, throat white, underparts very pale creamy yellowish; *scapularis* resembles previous; *exiguus* is smallest, male upperparts almost pure grey, wing edgings deep amber, female upperparts olive-grey. Voice. Loudsong of race *exiguus* short (e.g. 1-3 seconds) but complex, starts with flat, evenly paced series (e.g. 6 notes) that accelerates and drops in pitch before being

overtaken by rapid series of higher-pitched notes that decelerate; *frater* somewhat similar, except initial series of notes longer and drops in pitch, second part of song short and notes become raspy; *scapularis* (nominate race similar in pattern) starts with relatively clear whistles accelerating into rattling trill that decelerates, overall series rises and falls slightly in pitch. Calls include short raspy bark, short clear whistles, abrupt downslurred notes, and short (e.g. 0-4 seconds) rattle in which low-pitched initial notes followed by higher descending notes; calls appear to differ among populations.

**Habitat.** Lowland and foothill forests and forest borders, to 1500 m; throughout range, typically in interior vine tangles in mid-storey and subcanopy, but also in canopy of tallest trees and second growth. In Brazil, occupies interior of humid evergreen forest, less often edge, in Atlantic Forest region, locally also in taller *restinga* woodland growing on white-sand soils; primarily in river-edge forest in S Amazonia, but also in semi-deciduous *serra* forest growing on rocky, poor soils, and in borders of humid, tall *terra firme* forest. In Venezuela, mostly in humid foothill evergreen forest or gallery forest and second growth N of R Orinoco, and in dry (deciduous) to humid lowland and foothill forest S of river. Mostly in borders of humid foothill evergreen forest and in second-growth woodland in Ecuador and Peru.

**Food and Feeding.** Little published. Feeds on variety of insects, including lepidopteran larvae and orthopterans, and spiders; berries also recorded. Stomach contents of two specimens from Pará included orthopterans (Tettigoniidae), beetles (Curculionidae), hemipterans, and spiders; single stomach from Panama contained beetles (Chrysomelidae), ground bugs (Lygaeidae), homopterans, earwigs (Dermaptera), and spiders. Observed feeding on berries of mistletoe (*Rapanea*). Closely associated pair-members, individuals, or family groups forage mostly 8-30 m above ground, but regularly lower, to 3 m, at edges of lower-stature sandy-soil forest. Alone, or frequently with mixed-species flocks of other insectivores, pairs often join mixed flocks briefly as these pass through their territory, then lag behind and drop out as flock moves on. Active but methodical forager, progressing by short hops separated by frequent pauses of 1-3 seconds to scan for prey; concentrates activities in leafiest parts of canopy and subcanopy, especially in masses of vine tangles near trunk, but also in crown and periphery of trees where overlapping layers of leafy branches, vines and/or bamboo form dense mats or sprays of vegetation; works these areas thoroughly, in zigzag progression with frequent changes of direction and retracing of routes, routinely spending many minutes in a single tree or tangle before moving on. Most prey perch-gleaned from live leaves (more often from their tops), by reaching out, up or down with quick bill-stabbing motions or by short horizontal lunges; also makes frequent short (less than 30 cm) fluttering sallies to underside of vegetation; occasionally hangs head first to reach prey, but in general does not employ acrobatic manoeuvres; often flutters abruptly downwards, sometimes for several metres, in pursuit of dislodged prey. Small items swallowed immediately; larger prey bashed repeatedly against tree limbs before being swallowed. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Considered to be fairly common to common throughout most of range. Numerous protected areas exist in most countries in which it occurs, e.g. Darién National Park, in Panama, Henri Pittier and Guatopo National Parks, in Venezuela, Muriel Ecological Reserve, Sooretama Biological Reserve, Serra do Mar and Cristalino State Parks, and Tijuca and Iguaçu National Parks, in Brazil, and Iguazú National Park, in Argentina; also extensive tracts of intact habitat which are not formally protected, but are seemingly at little immediate risk of development. The species' capacity to exploit a number of different habitats, including forest edge and second-growth woodland, renders it less vulnerable to disturbance than are many other antbirds.

**Bibliography.** Aleixo (1999), Alverson *et al.* (2001), dos Anjos (2001a), Berla (1946), Cândido (2000), Cory & Hellmayr (1924), Cox *et al.* (1992), Davis & O'Neill (1986), Foster *et al.* (1994), Gonzaga (2001), Hackett & Rosenberg (1990), Hilty (2003a), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Killeen & Schulenberg (1998), Krügel & dos Anjos (2000), Meyer de Schauensee & Phelps (1978), Moskovits *et al.* (1985), Motta-Junior & Vasconcello (1996), Parker & Carr (1992), Pineschi (1990), Remsen *et al.* (1986), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Schubart *et al.* (1965), Scott & Brooke (1985), Sick (1993), Stotz (1990b), Stotz, Fitzpatrick *et al.* (1996), Stotz, Lanyon *et al.* (1997), Taylor (1995), Terborgh & Weske (1969), Wetmore (1972), Zimmer, J.T. ## Genus *MICRORHOPIAS* P. L. Slater, 1862

### 114. Dot-winged Antwren

#### *Microrhopias quixensis*

**French:** Grisé étoilé **German:** Tropfenflügel-Ameisenfänger **Spanish:** Hormiguero del Quijos

**Taxonomy.** *Thamnophilus quixensis* Cornalia, 1849, eastern Ecuador.

Relationships uncertain; extensive study of morphological and vocal characters indicated close relationship with *Formicivora*; genetic study in which latter genus not included, however, suggested closeness to "stipple-throated antwren assemblage" of *Myrmotherula*. Races *boucardi* and *virgatus* intergrade in Honduras; future research may indicate that they should be merged. On basis of vocal as well as plumage differences, possibly also differences in habitat preferences, it is very likely that some other races merit elevation to species rank; e.g. *emiliae* suggested as a separate species; further study required. Ten subspecies recognized.

#### Subspecies and Distribution.

*M. q. boucardi* (P. L. Slater, 1858) - E Mexico (E Veracruz and NE Oaxaca E to S Campeche and S Quintana Roo), Belize, E Guatemala and N Honduras.

*M. q. virgatus* (Lawrence, 1863) - SE Honduras and E Nicaragua S to W Panama (E to E Panamá and W San Blas, locally on Pacific slope).

*M. q. consobrinus* (P. L. Slater, 1860) - E Panama (E San Blas, Darién), W & N Colombia and W Ecuador.

*M. q. microstictus* (Berlepsch, 1908) - NE Amazonian Brazil (N Roraima, extreme NE Pará, Amapá), S Guyana, Surinam and French Guiana.

*M. q. quixensis* (Cornalia, 1849) - S Colombia (Putumayo, Caquetá), E Ecuador and NE Peru (N Loreto N of R Marañón and R Amazon).

*M. q. intercedens* J. T. Zimmer, 1932 - lowlands of C Peru (S of R Amazon and along both banks of R Ucayali) and SW Amazonian Brazil (E to R Madeira).

*M. q. nigriventris* Carriker, 1930 - E slope and base of Andes in C Peru (San Martín S to N Cuzco).

*M. q. albicauda* Carriker, 1932 - SE Peru (S Cuzco, SE Ucayali, Madre de Dios, Puno) and adjacent N Bolivia (Pando).

*M. q. bicolor* (Pelzeln, 1868) - SC Amazonian Brazil (R Madeira E to R Tapajós and R Teles Pires, S to Rondônia and N & W Mato Grosso).

*M. q. emiliae* Chapman, 1921 - R Tapajós E to R Tocantins and S to extreme N Mato Grosso (NE of R Teles Pires).

**Descriptive notes.** 11-12 cm; 7.5-11.5 g. Long tail graduated. Male nominate race is mostly black; partly concealed white interscapular patch extending to rump; flight-feathers dark grey, tinged brown, greater wing-coverts with large white tips, remaining coverts with small white tips; tail feathers (except central ones) with white tips, becoming progressively larger to outside; sometimes a few white shaft streaks on flanks; axillaries, underwing-coverts and inner margins of flight-feathers white. Female is like male except blackish-grey, throat black, remaining underparts rufous-chestnut, darkest

on breast. Males of other races differ from nominate mainly in size of white wing-covert and tail spots, and plumage of female: *boucardi* has tail tips smaller, female throat and underparts rufous-tinged cinnamon; *virgatus* is like last, but female cinnamon-rufous below; *consobrinus* is distinctly smaller in size, white tail tips larger, female entirely rufous-chestnut to rufous below; *microstictus* has wing-covert spots small, female throat and underparts rufous, flanks mixed with dark grey; *nigriventris* has primary wing-coverts extensively white, outer tail feathers almost entirely white, female deep chestnut on breast, remaining underparts black; *albicauda* has greater wing-covert spots small, white tips of tail feathers longer, outer rectrices almost entirely white, female crown and anterior upperparts dark grey, cinnamon-rufous below, flanks grey; *bicolor* has white tail tips extensive, female upperparts dark grey, throat and underparts rufous; *intercedens* is similar to previous, but female blackish-grey above; *emiliae* has white tail tips smaller, female lower throat and upper breast chestnut-rufous, remaining underparts black. Voice. Loudsong an accelerating series of notes that shorten in length, varies among races in such characteristics as number of notes, duration, overall pace, and especially frequency pattern, some songs rise and fall in frequency, others are flat or fall or rise throughout, differences among taxa remain to be determined through careful analysis; also much sexual and individual variation within populations. Most common call a short, sharp, mostly downslurred note, often repeated over and over but at irregular pace; other calls include downslurred whine, downslurred complex, raspy call, and jumble of "chip" and "see" notes.

**Habitat.** Mid-storey of humid lowland and foothill evergreen-forest borders, light-gaps within primary forest, and adjacent second-growth woodland, from near sea-level to 1100 m (lower in some parts of range). Mostly in dense edge and second-growth vegetation, and usually not in interior of forest except where light-gaps have fostered abundant vine tangles in mid-storey; in most regions, found especially in vine tangles and dense mats of vegetation around edges of forest clearings, particularly around treefalls. In parts of Central America (e.g. Guatemala, Belize) also occurs in low, dense, semi-deciduous forest, which often characterized by mats of vine vegetation overtopping the understorey trees and shrubs; in some areas (e.g. Costa Rica, Panama) often ventures into the shaded, semi-open of regenerating cacao and guava plantations. In some regions of South America (e.g. W Ecuador, SE Peru, parts of Brazil) is strongly tied to stands of bamboo and/or *várzea* forest. In Alta Floresta region of Mato Grosso, occupies mainly vine tangles in *terra firme* light-gaps W of R Teles Pires (race *bicolor*), but E of the river restricted to stands of *Guadua* bamboo (*emiliae*).

**Food and Feeding.** Feeds on a variety of insects, including orthopterans, hemipterans, and adult and larval lepidopterans; also on spiders. Stomach contents of specimens from Surinam included hemipterans, homopterans, and beetles (Chrysomelidae). Forages as closely associated pair-members or family groups, rarely singly, mostly 3-10 m above ground, less commonly down to 1 m or as high as 15 m; mean foraging height from 33 foraging observations at Cocha Cashu, in Peru, was 8-91 m. Alone, or with mixed-species flocks of other insectivores; typically, joins mixed flocks briefly as these pass through its territory, but pairs and families usually drop out as flocks move on. Concentrates activities in dense foliage, particularly in vine tangles along trunks and major limbs and in dense thickets, but also in leafy crowns of understorey trees and bamboo. Forages very actively, frequently fluttering and posturing with half-drooped wings (habitually flicked) and fanned tail, progressing by short hops and fluttery flights with frequent abrupt changes of direction; hitches up vertical vines and stems, often moving rapidly up and down in vertical profile. Perch-gleans prey from tops and bottoms of live leaves, leaf petioles and stem and vine surfaces; *virgatus* prefers very large leaves, particularly those of philodendrons (*Philodendron*), *emiliae* more often gleans from small leaves of *Guadua* bamboo. Reaches out, up or down (often with legs extended) with quick stabs of the bill; also, often makes short, upward-directed jump-strikes or horizontal lunges, and short (less than 40 cm) hover-gleaning sallies; occasionally hangs head first or clings laterally to glean from vegetation. Rarely attends army-ant swarms; at such times, descends to the ground and takes prey directly from ground.

**Breeding.** May-Jul in Mexico and Belize, Jan-Aug in Costa Rica and Feb-Jul in Panama; probably Feb-Sept in Surinam, and adults carrying food in bill in Mar-Apr in French Guiana; single record of adult male feeding juvenile male in Feb in E Ecuador. Nest, constructed by both sexes, a pouch or deep cup composed of partly decayed leaves, fastened together with cobwebs and fine dark fibres, also sparsely lined with latter material, attached by rim to forked branch and slender twigs 1-12 m (mostly 4-7 m) above ground among foliage. Normal clutch 2 eggs, white, spotted all over with brown, lilac-grey, dark purple-grey and/or dark violet-brown, spots more heavily clustered on larger end; incubation by both parents during day, only female at night; brooding and feeding of

nestlings shared by both parents. Of 11 nests followed in one study in Panama, 4 fledged young, 6 were preyed on, and 1 failed for unknown reasons.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common but patchily distributed throughout most of its extensive range. This includes numerous large protected areas, examples of which are: Tikal National Park, in Guatemala; Chan-Chich, in Belize; Braulio Carrillo, La Amistad and Corcovado National Parks and Carara Biological Reserve, in Costa Rica; Soberania and Darién National Parks and Comarca Kuna Yala Indigenous Reserve, in Panama; Raleigh Falls-Voltzberg National Park, in Surinam; Yasuni National Park, Río Palenque Scientific Centre and Jatun Sacha Biological Station, in Ecuador; Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru; and Serra do Divisor, Pacaás-Novos and Tapajós National Parks and Cristalino State Park, in Brazil. Existing parks and reserves are adequately distributed throughout the species' range, ensuring protection of all subspecies. Considered to be of medium sensitivity to human disturbance.

# Genus *FORMICIVORA* Swainson, 1824

## 115. Narrow-billed Antwren

### *Formicivora iheringi*

**French:** Grisin à bec étroit

**Spanish:** Hormiguerito Picofino

**German:** Schiefergrauer Ameisenfänger

**Taxonomy.** *Formicivora iheringi* Hellmayr, 1909, Senhor do Bonfim, Bahia, Brazil.

Relationships unclear. Recent extensive morphological and vocal study indicated that it is not closely related to others of genus, and that it should perhaps, for the time being, be placed in a separate monotypic genus; further research required. Monotypic.

**Distribution.** E Brazil in interior E Bahia and NE Minas Gerais.

**Descriptive notes.** 11-12 cm; 1 male 8-2 g. Male is mostly dark grey; blackish-grey on wings and tail, wing-coverts and outer tail feathers tipped white; centre of throat and breast black, flanks white, undertail-coverts indistinctly barred white. Female is olive-brown above, contrastingly greyer on crown, shading to reddish yellow-brown on uppertail-coverts; pale supercilium, diffuse whitish eyering; wings dull brown, flight-feathers edged reddish, coverts edged pale cinnamon; tail reddish-brown; yellow-ochre below, paler, nearly whitish, in centre of belly, little white on flanks. **VOICE.** Loudsong a countable series

(e.g. 19 notes, 8 seconds) of emphatic, evenly paced, downslurred whistles, notes start a little softer, then maintain intensity. Calls include abrupt notes, often in pairs or triplets, and short rattle.

**Habitat.** Understorey and mid-storey of tropical deciduous hill forest, from 250 m to 1050 m. In Jequié-Boa Nova region (Bahia) occupies vine-rich *mata-de-cipó* forest, which has scattered larger trees above a uniform dense layer of mid-storey trees and vines, and relatively open understorey, with numerous lianas and scattered patches of huge terrestrial bromeliads.

**Food and Feeding.** Little published. Feeds on variety of insects, including orthopterans (Tettigoniidae) and adult and larval lepidopterans; probably also on spiders. Closely associated pair-members, individuals, or family groups forage 0-12 m above ground, mostly at 1-5-8 m, generally alone, sometimes in loose association with mixed-species flocks. Active but methodical forager, progressing by short hops, separated by pauses of 1-2 seconds to scan; concentrates foraging in shaded open branches and woody vine tangles in central portions of trees, generally avoiding areas of dense foliage; hitches up hanging vines and vertical branches, sometimes turning from side to side with each hop, but just as commonly maintaining a single (nearly vertical) orientation, more like a piculet (*Picumnus*); when working along horizontal and inclined limbs, routinely leans far forwards to peer under branches in manner reminiscent of many *Tangara* tanagers; follows zigzag progression, with frequent changes of direction, and often abruptly drops to lower perch, only to start hitching upwards again. Posture generally horizontal; shallowly flicks both wings constantly, and regularly raises tail slowly to perhaps 10 degrees above plane of body before rapidly flicking it downwards in 20-30 degree arc. Of more than 200 foraging observations in Bahia, over 60% of attack manoeuvres were targeted at bare branch, vine or stem surfaces, including leaf petioles; remaining foraging substrates were, in decreasing order of importance, live leaves (upper and lower surfaces), suspended arboreal dead leaves, small bromeliads and clumps of moss along trunks, and hanging clumps of *Tillandsia*; curled dead leaves were regularly investigated (c. 15% of all manoeuvres) but just as frequently passed by without inspection. When investigating dead leaves, typically probes the interior lightly with its bill, sometimes while clinging to leaf itself, but rarely manipulates or damages it, and seldom spends more than 5 seconds at a single dead leaf. Perch-gleans most prey by reaching out, up or down with quick bill-stabbing motions; frequently hangs acrobatically, head first, to reach prey below, and also clings in manner of a tit (*Paridae*) to branch, vine or leaf margins and hanging clumps of *Tillandsia* or moss; regularly makes short (less than 30 cm) sallies or jump-strikes to glean prey from undersides of overhanging vines or leaves; also regularly makes fluttering pursuit-flights after flushed prey (particularly moths). Rarely, recorded as briefly attending swarms of army ants (*Eciton burckhelli*).

**Breeding.** Little known. Three birds had testes dormant or only slightly enlarged in Oct (Bahia) and Dec (Minas Gerais), indicating that breeding does not occur during local dry season.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Deciduous Forests of Bahia EBA. Uncommon to fairly common within its small range; total population thought to number between 2500 and 10,000 individuals, and assumed to be declining as a result of ongoing habitat destruction. Primary deciduous forest in Bahia and NE Minas Gerais is being rapidly cleared for cattle pastures and coffee plantations, and remaining fragments subject to disturbance by livestock and exploitation of trees for firewood. Nevertheless, substantial habitat harbouring viable populations of this species still exists in Jequié-Boa Nova region (Bahia) and at Almenara in Jequitinhonha Valley (Minas Gerais), although neither area is formally protected. There have been calls for establishment of a forest reserve of *mata-de-cipó*; this could be set up in conjunction with an experimental agricultural station that is needed on S Bahian plateau because of its distinctive climate and soils, or as a community-level conservation initiative. Creation of such a reserve in Jequié-Boa Nova region would also help to protect the Endangered *Rhoportis ardesiacus*.

## 116. White-fringed Antwren

### *Formicivora grisea*

**French:** Grisin de Cayenne

**Spanish:** Hormiguerito Coicorita

**German:** Braunrücken-Ameisenfänger

**Other common names:** Black-breasted Antwren

**Taxonomy.** *Turdus griseus* Boddaert, 1783, Cayenne, French Guiana.

Morphological, vocal and molecular studies indicate that, with exception of *F. iheringi*, all species placed in current genus form a well-defined group. Recent extensive morphological and vocal study suggests that closest relatives of present species are *F. rufa* and *Stymphalornis acutirostris*; close relationship with former also supported by genetic study. Geographical differences in voice and striking differences in female plumages strongly suggest that some races represent separate species; further study required. On other hand, *fumosa* possibly indistinguishable from *intermedia*. Described form *delizae* known from single specimen from Rio de Janeiro (Brazil); possibility that it represents a distinct race considered unconfirmed. Eight subspecies recognized.

**Subspecies and Distribution.**

*F. g. alticincta* Bangs, 1902 - Pearl Is, S Panama.

*F. g. hondae* (Chapman, 1914) - NW Colombia (Atlántico S to N Antioquia and Bolívar, S in Magdalena Valley to Huila).

*F. g. intermedia* Cabanis, 1847 - N Colombia (Magdalena, La Guajira, César) and N Venezuela (N Zulía E to Sucre and Monagas, including Margarita I); also Chacachacare I, off Trinidad.

*F. g. tobagensis* Dalmás, 1900 - Tobago.

*F. g. fumosa* (Cory, 1913) - along N base of Andes in NE Colombia (E Norte de Santander) and Venezuela (S Zulía and Trujillo S to Táchira).

*F. g. rufiventris* Carriker, 1936 - E Colombia (Meta and Guainía S to Caquetá) and S Venezuela (W Amazonas except extreme N).

*F. g. orenocensis* Hellmayr, 1904 - S Venezuela (S of R Orinoco in Bolívar and extreme N Amazonas).

*F. g. grisea* (Boddaert, 1783) - Guyana, coastal Surinam and French Guiana, and N & E Brazil (drainage of R Branco, lower R Negro E to Amapá and S of R Amazon, E from R Madeira apart from few scattered records W of it to W Amazonas, and S to Mato Grosso, Goiás, Bahia and, locally, to E Minas Gerais and N Rio de Janeiro).

**Descriptive notes.** 12-13 cm, *alticincta* 11-12 cm; 8-12 g. Male nominate race has white supercilium, dark greyish-brown crown and upperparts, crown with blackish feather centres, outer scapulars edged white, concealed white interscapular patch; wings brownish-black, coverts tipped white; graduated tail black, sides white, small white tips on central feathers, white tips increasing in size towards outer rectrices; white of supercilium extending in a line to breast side and broadening on flanks; head side, throat and remaining underparts black, underwing-coverts white. Female

resembles male above, except supercilium tinged buff, hidden white interscapular patch reduced or absent, wings browner, side of head mottled blackish and pale buff-white; cinnamon below, whiter on throat and belly, breast tinged tawny. Subadult male initially resembles female, later acquires black throat and breast before complete adult male plumage. Races vary in depth of colour above, extent of white on tail tips, darkness of male crown-feather centres, but mainly in female colour of throat and underparts: *alticincta* female has throat and underparts whitish, tinged cinnamon; *hondae* resembles previous but upperparts paler; *intermedia* male duller and paler above, female white below, variably streaked or spotted black on throat and anterior underparts; *fumosa* is like last, but darker and more heavily spotted; *rufiventris* female is entirely rufous below; *orenocensis* is highly distinctive, dull reddish yellow-brown above in both sexes, female entirely white below with heavy black streaks; *tobagensis* female is buff-tinged white below, anterior underparts spotted blackish. **VOICE.** Loudsong a monotonous series of dry or harsh notes repeated at same pitch and pace, rate of delivery varies among populations from short and countable (e.g. 7 notes, 2 seconds) to long and uncountable (e.g. 25 notes, 4 seconds); at least some populations also deliver musical trill preceded by longer note, stereotyped like a song. Calls also vary regionally, typically include doubled notes, some entirely harsh in quality, others incorporating a whistle, these notes also given individually.

**Habitat.** Understorey and mid-storey of a variety of wooded habitats, generally at edges; typically below 1000 m, but to 1600 m in Venezuela. In some areas occupies several habitats, but most regional populations tend to be habitat-restricted. In parts of the Guianas, nominate race is found in mangroves. More of a generalist in N Venezuela (*intermedia*), utilizing several habitats within same region, including thickets along deciduous-forest borders and seasonally flooded savannas, taller deciduous thorn-scrub, gallery-forest borders, second-growth scrub, as well as mangroves. Generally restricted to either white-sand "campina" woodland or young second-growth in S Venezuela, SE Colombia and Brazil N of R Amazon (*orenocensis* and *rufiventris*). S of R Amazon, variously occupies humid second growth and riparian vegetation in Amazon Basin, *restinga* scrub on white-sand soil in coastal NE Brazil, and tropical deciduous forest and *caatinga* scrub in interior NE Brazil.

**Food and Feeding.** Feeds on variety of insects and spiders. Recorded prey items in Surinam include hemipterans, homopterans, larval lepidopterans, coleopterans, also ootheca of cockroaches (Blattidae); in Brazil (Pará and Maranhão) include orthopterans (Acridoidea), cockroaches, hemipterans, coleopterans (Scolytidae), larval lepidopterans, termites (Isoptera), and spiders. In NE Brazil (Ceará), also observed to take mantids (Mantidae), stick-insects (Phasmatidae) and hemipterans. Closely associated partners, individuals, or family groups forage mostly 0-5 m above ground, but to 13 m in deciduous or gallery forests; median foraging height in 643 observation in Brazil (nominate race) was c. 0-6 m. Forages alone, or temporarily joins mixed-species flocks of other insectivores. In greater part of range (nominate race and *rufiventris*) forages mostly in interior of densely foliated shrubs and understorey saplings; in N Mato Grosso, Brazil, nominate race also found to forage extensively within patches of terrestrial bromeliads, where it gleans prey directly from blades of these plants and from trapped leaf litter; in NE Colombia and N Venezuela (*intermedia*) mostly in dense, viny tangles, either in crowns of shrubs and low saplings overgrown over with masses of clinging herbaceous vines, or in clusters of hanging woody vines and tendrils

that cling to larger tree trunks, also regularly in weedy thickets of dead herbaceous growth. Active forager, moving by short hops, usually on thin branches, and fluttery flights, frequently pausing for 1-2 seconds to scan for prey; posture mostly horizontal, tail held partly fanned and often swung from side to side (occasionally pounded down), wings held slightly drooped and constantly flicked (shallowly). Hitches from side to side up vertical vines, stems and branches, often leaning forward to peer under branches. Most prey perch-gleaned from live leaf, stem, vine and branch surfaces by reaching out, up or down with quick stabs of the bill, or by short horizontal lunges; occasionally makes fluttery pursuit-sallies after flushed prey (particularly moths), as well as downward and upward diagonal sallies of up to 50 cm to glean prey from foliage, branches or vines; birds inhabiting scrub, deciduous forest and tall *caatinga* woodland regularly drop to ground to take prey from leaf litter; does not hang or make other acrobatic manoeuvres. Occasionally investigates suspended dead leaves, but more often ignores them. Small prey immediately swallowed, larger items bashed repeatedly against branch before being consumed; prey capture usually followed by vigorous wiping of the bill on a branch. Five records from Amazonian Brazil of briefly following swarms of army ants (*Eciton burchellii*).

**Breeding.** Season varies considerably across broad range: Apr-Oct in Colombia, Aug and Mar in French Guiana, Apr-Aug on Chacachacare I and Tobago; in Brazil, nesting recorded in Sept-May and dependent juveniles in Aug-Sept in Amazonia, and a nest in Dec in Pernambuco. Nest a thinly woven cup composed of grass stems and fine plant fibres, suspended by rim from horizontal fork 0.3-3.5 m above ground; a nest in French Guiana was constructed by both sexes, and hung 80 cm off ground in two plants of the nettle family (*Urticaceae*) in second growth. Normal clutch 2 eggs, creamy white or greyish-white, with spots, streaks and blotches of lilac, brown, lavender-grey and deep purple concentrated at larger end and forming cap or wreath.

**Movements.** Presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout most of its rather extensive range. Some large protected areas exist within regions inhabited by this species: examples include Henri Pittier, Guatopo, Cueva de la Quebrada El Toro, Cerro El Copey/Isla Santa Margarita, Morrocoy and Yapaacana National Parks, in Venezuela, and Tapajós and Araguaia National Parks, Roraima National Forest, Cristalino State Park and Porto Seguro Reserve, in Brazil. In addition, range covers extensive areas of habitat which, although not formally protected, are at little risk of development in the near future; these include the many huge *hatos* (ranches) in the *llanos* region of Venezuela, many of which rival some national parks in size, and harbour healthy populations of this antwren. This species' ability to utilize a variety of second-growth and edge habitats renders it less vulnerable to disturbance than are most thamnophilid species.

## 117. Serra Antwren

### *Formicivora serrana*

French: Grisin des montagnes German: Serraameisenfänger Spanish: Hormiguerito Serrano

**Taxonomy.** *Neorhopias serrana* Hellmayr, 1929. Sete Lagoas, Minas Gerais, Brazil.

Morphological, vocal and molecular studies indicate that, with exception of *F. iheringi*, all species placed in current genus form a well-defined group. Present species considered to belong to a clade along with *F. littoralis* and *F. melanogaster*. Forms a superspecies with former, with which previously considered conspecific but found to differ in morphology and ecology; also, has been treated as race of latter. Two subspecies recognized.

**Subspecies and Distribution.**

*F. serrana* (Hellmayr, 1929) - SE Brazil (E Minas Gerais and adjacent C Espírito Santo).

*F. interposita* Gonzaga & Pacheco, 1990 - valley of R Paraíba do Sul in extreme SE Minas Gerais and adjacent NW Rio de Janeiro.

**Descriptive notes.** 12-13 cm; 10-13 g. Male nominate race has long white supercilium, rufous-brown crown and upperparts, outer scapulars edged white, concealed white interscapular patch; wings brownish-black, remiges blackish near base, tertials edged cinnamon-brown, wing-coverts tipped white; tail graduated, black, sides white, tips with white spots, spots becoming larger towards outer rectrices; head side, throat and underparts black, narrow white line on breast side becoming somewhat broader and greyer on flanks; underwing-coverts white. Female differs from male in having entire underparts creamy white,

sometimes tinged buff, contrasting with broad black eyband. Race *interposita* male differs from nominate in blackish upperparts, narrow and broken supercilium, white tips of lesser and median wing-coverts diminutive, no white below. Voice. Loudsong a monotonous series of dry or harsh notes at same pitch and pace (e.g. 18 notes, 4 seconds), resembling that of *F. grisea*. Calls include short (e.g. 0.1 second) downslurred whine given singly or in regular series of up to 8 notes; also thin sharp note.

**Habitat.** Understorey of semi-humid evergreen-forest edge, dry scrub and second-growth woodland, to 1550 m; race *interposita* to 700 m. Nominative form found especially in stunted *serra* woodland growing on nutrient-poor, rocky soils, such habitat having canopy height 4-10 m, few trees with trunk diameter more than 8 cm, and liberal patches of small-leaved bamboo, bracken-ferns and terrestrial bromeliads in understorey; also in shrubby thickets at edge of taller forest growing on richer soils. Race *interposita* in second-growth woodland in valley floor and surrounding foothills. Colonizes eucalyptus (*Eucalyptus*) plantations in Minas Gerais.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly 0.4-4 m above ground, chiefly 1-2 m, but occasionally to 8 m; alone, or sometimes with mixed flocks of other insectivores. Active forager,

progressing by short hops and fluttery flights, separated by frequent pauses of 1-2 seconds to scan for prey; moves in zigzag progression, usually hitching from side to side; posture mostly horizontal with tail held cocked at c. 10 degrees and partly spread, both wings habitually flicked shallowly when foraging. Perch-gleans most prey from tops and bottoms of live leaves, stems and branches, by reaching up, out or down with quick bill-stabbing motions or by short horizontal lunges; also makes short hover-gleans or sallies of less than 30 cm, mostly to underside of overhanging vegetation. Frequently inspects suspended dead leaves, probing the curls lightly with the bill but not otherwise manipulating them, but just as frequently ignores dead leaves, even when close at hand. Regularly drops to the ground to forage; when doing so, spends most of time looking up and jump-gleaning prey from undersides of overhanging leaves or branches, only occasionally taking prey from surface of leaf litter. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Locally fairly common in appropriate habitat. Nominative race known to occur in Serra do Cipó and Caraça National Parks, both in Minas Gerais. This species' basic ecology is little known, and its minute geographical range leaves it vulnerable. Fact that it occupies second-growth woodland and scrub makes it more secure than are true forest birds, but even secondary habitats in foothills of this region are being cleared for cattle pastures and agriculture; this perhaps especially true of parts of Rio de Janeiro occupied by *interposita*. Fortunately, has been found to colonize eucalyptus plantations where native understorey allowed to grow. Surveys needed in order to assess total population and more precisely to identify species' habitat requirements.

**Bibliography.** Christiansen & Pitter (1989), Collar *et al.* (1994), Ferreira de Vasconcelos & Melo-Júnior (2001), Gonzaga (2001), Gonzaga & Pacheco (1990), Isler & Whitney (2002), Machado & Lamas (1996), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias & Williams (1996), Wege & Long (1995), Willis & Oniki (1991), Zimmer (2003a).

## 118. Restinga Antwren

### *Formicivora littoralis*

French: Grisin du restinga German: Restingaameisenfänger Spanish: Hormiguerito Litoral

**Taxonomy.** *Formicivora serrana littoralis* Gonzaga and Pacheco, 1990, Maçambaba beach, Arraial do Cabo, Rio de Janeiro, Brazil.

Morphological, vocal and molecular studies indicate that, with exception of *F. iheringi*, all species placed in current genus form a well-defined group. Present species considered to belong to a clade along with *F. serrana* and *F. melanogaster*. Forms a superspecies with former and previously considered conspecific, but accorded species status on basis of differences in morphology and ecology; also, has been treated as race of latter. Monotypic.

**Distribution.** SE Brazil in coastal Rio de Janeiro (municipalities of Cabo Frio, São Pedro da Aldeia, Arraial do Cabo, Araruama, Saquarema) and nearby offshore islands of Comprida and Cabo Frio.

**Descriptive notes.** 13-14 cm; 14-16 g. Male is mostly blackish above and below; outer scapulars edged white, concealed white interscapular patch, greater wing-coverts tipped white, lesser and median coverts sometimes with small white tips (often absent), tail feathers with small white tips, flanks grey. Distinguished from *F. serrana* of race *interposita* by larger size, no supercilium, less white on wing-covert and tail tips. Female differs from male in brown crown and upperparts, white supercilium from above eye, broad black eyband contrasting with entirely creamy white to buff-tinged underparts. Voice. Loud-

song a monotonous series of harsh or dry notes at even pitch and pace (e.g. 12 notes, 1.8 seconds), resembling that of *F. grisea*. Short calls appear to be highly variable, a flat note dropping in pitch at end and a downslurred note recorded; also abrupt upslurred squeak and short (e.g. 0.9 seconds) musical rattle.

**Habitat.** Restricted to *restinga* scrub (nearly impenetrable shrubby thickets with abundant cacti and terrestrial bromeliads, on white-sand soil) of sandbars, sand dunes and coastal and island hill-sides near sea-level. Habitats occupied range from sand dunes with scattered shrubby thickets less than 3 m tall to extremely dense, swampy woodland with average canopy height of 6-7 m. Sometimes forages out into adjacent grassy glades with scattered shrubs.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated partners, individuals, or family groups forage mostly 0.5-4 m above ground, usually alone, but may accompany mixed-species flocks of other insectivores in taller *restinga* woodland. Utilizes all strata of shrubbery and trees, but most foraging done in shaded inner portions of shrubby thickets. Active forager, progressing by short hops and fluttery flights, separated by frequent pauses of 1-2 seconds to scan for prey; maintains horizontal posture, habitually swinging tail from side to side. Mostly perch-gleans prey from live leaves and stems (c. 70% of all attack manoeuvres; particularly to undersides of leaves), woody branches and trunks, by reaching out, up or down with quick stabs of the bill, or by short horizontal lunges; also regularly makes short (less than 20 cm) jump-sallies to glean prey from beneath overhanging vegetation. Smaller items immediately swallowed, but larger ones bashed repeatedly against limbs before being consumed; wipes bill on branches after each prey capture. Not known to follow army ants.

**Breeding.** Three nests found in Jun, Oct and Nov on Cabo Frio I; on basis of gonadal condition of birds, breeding season thought to extend almost throughout year. Nest built by both sexes, described as a deep open cup made of vegetable fibres, attached to horizontal branch fork 1.7-2.1 m above ground. Clutch 2 eggs; both parents incubate eggs and care for young; post-fledging parental care continues until juveniles can fend for themselves.

**Movements.** Presumed resident.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Atlantic Forest Lowlands EBA. Locally abundant e.g. on Cabo Frio I, access to which is restricted by Brazilian navy. This is a habitat specialist occupying a minute range within a major vacation development area of prime beach real estate. Suitable habitat is under pressure from clearance for real-estate projects and increasing presence of squatters; type locality, near Arraial do Cabo, is severely threatened by the salt industry and development of beach-front housing. Small amounts of *restinga* are protected by three designated areas: the Jacarepiá and Maçambaba State Reserves, and the Maçambaba Environmental Protection Area. Nevertheless, total population thought to number fewer than 1000 individuals, and assumed to be declining owing to ongoing habitat destruction. Ensured continued support for protected areas where the species occurs is critical to its continued survival;

establishment of a new sizeable *restinga* reserve within areas where species occurs at highest densities is desirable. In addition, periodic monitoring of population is needed, and ecological-impact assessments must be required for any proposed major development projects within this narrow coastal strip.

**Bibliography.** Coelho *et al.* (1991), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Gonzaga (2001), Gonzaga & Pacheco (1990), Isler & Whitney (2002), Ridgely & Tudor (1994), Sick (1993, 1997), Soneghet (1991), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Tobias & Williams (1996), Wege & Long (1995), Zimmer (2003a).

## 119. Black-bellied Antwren

### *Formicivora melanogaster*

**French:** Grisin à ventre noir

**Spanish:** Hormiguero Ventrinegro

**German:** Dunkelrücken-Ameisenfänger

**Taxonomy.** *Formicivora melanogaster* Pelzelin, 1868, Goiás city, Goiás, Brazil.

Morphological, vocal and molecular studies indicate that, with exception of *F. iheringi*, all species placed in current genus form a well-defined group. Present species considered to form a clade with *F. serrana* and *F. littoralis*, and all three have sometimes been treated as conspecific. Two subspecies recognized.

#### Subspecies and Distribution.

*F. m. bahiae* Hellmayr, 1909 - NE Brazil (extreme E Maranhão E to W Rio Grande do Norte, S to N Bahia and W Pernambuco).

*F. m. melanogaster* Pelzelin, 1868 - C Brazil (S Mato Grosso E to S Bahia, S to W Mato Grosso do Sul, W São Paulo and N Minas Gerais), SE Bolivia (Santa Cruz, Chuquisaca, Tarija) and extreme N Paraguay (Alto Paraguay).

**Descriptive notes.** 12-13 cm. Male nominate race has broad white supercilium, dark greyish-brown crown and upperparts, crown feathers with blackish centres, outer scapulars edged white, concealed white interscapular patch; wings blackish, coverts tipped white; graduated tail black, sides white, white tips on central feathers, white tips becoming larger towards outer rectrices; white of supercilium extending in a line to breast side and broadening on flanks; head side, throat and remaining underparts black, underwing-coverts white. Distinguished from very similar *F. grisea* by broader supercilium, especially behind eye.

less white on flanks. Female differs from male in browner crown and upperparts, interscapular patch reduced or absent, broad black eyeband contrasting with white throat, faintly buff-tipped white underparts. Race *bahiae* is paler above, tail with smaller white spots, wider white line connecting supercilium and flanks on male. **VOICE.** Loudsong a monotonous series resembling that of *F. grisea*, but pace very slow (e.g. 14 notes, 6 seconds), sometimes becoming irregular. Calls include a short series of complaining squeals (e.g. 5-15 notes at 5 notes per second), variable in frequency and pace; also sharp high-pitched "seek" notes and lower-pitched, short downslurred notes; calls may vary regionally.

**Habitat.** Understorey and mid-storey of tropical deciduous forest (including *mata-de-cipó* vine forest) and taller *caatinga* scrub, from lowlands to 1050 m. Also ventures into degraded *caatinga* with taller second-growth scrub, as well as ecotones between *caatinga* and *cerrado*.

**Food and Feeding.** Little published. Feeds on variety of insects, including orthopterans and lepidopteran larvae, and spiders. Closely associated partners, individuals, or family groups forage mostly 0-3 m above ground, regularly to 6 m in dry forest in N Minas Gerais (Brazil), alone or, sometimes, with mixed-species flocks. Forages actively, mostly in dense thickets of deciduous shrubs and vine tangles, progressing by short hops and fluttery flights, separated by frequent pauses of 1-2 seconds to scan for prey; posture horizontal, partially fanned tail habitually swung from side to side, both wings shallowly flicked. Moves erratically, in zigzag progression with frequent abrupt changes of direction and retracing of routes; works small areas thoroughly before moving on; hitches from side to side up vertical stems. Perch-gleans prey from leaf, stem, vine and branch surfaces, by reaching out, up or down with quick bill-stabbing motions or by short horizontal lunges; also makes short (less than 40 cm) sallies and hover-gleans to vegetation, vines and branches; in *mata-de-cipó* woodland regularly forages within large terrestrial bromeliads, probing beneath leaf litter trapped by the blades; also regularly drops to ground to forage in leaf litter, using bill to poke underneath leaves and occasionally to flip smaller ones. Sometimes investigates suspended arboreal dead leaves, but just as often ignores them. Prey capture typically followed by vigorous wiping of the bill on a branch. Smaller prey immediately swallowed; larger items repeatedly bashed against branches before being consumed. Not known to follow army ants.

**Breeding.** In Brazil, nest with young in Pernambuco and another in earliest stages of construction in Bahia (both previously unpublished), both in Jan. Nest was an open cup 8 cm in height (from bottom to highest point of attachment), external diameter 6 cm, inside depth 3 cm, thinly woven, lined with fine grass fibres and stems, secured with spider webs around edges, suspended by rim from horizontal fork of dead branch (and further secured by fibres at one end of rim looping over a branch crossing over fork), distance from bottom of nest to ground 16 cm; fork was among cluster of thin, dead branches of a woody shrub, surrounded by scattered forbs, and with shading canopy of bare woody vines and branches 1 m above nest. Contained 2 nestlings, one obviously larger than the other, mouth-lining rich golden-yellow; fed by both parents; after one feed, female removed a faecal sac, flew low for 5-6 m, took several short hops on ground, then dropped sac and proceeded to wipe bill on a branch, before resuming foraging.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its range. Reliance on deciduous forest and *caatinga* makes it more sensitive to disturbance than are some congeners which occupy a variety of disturbed, secondary habitats. Much of region in which it occurs lacks formal protection. The dry forests, *caatinga* scrub and *mata-de-cipó* woodlands favoured by this species are being rapidly cleared for cattle pastures and coffee plantations; even where such habitats not being cleared, they are heavily exploited by local people for firewood and fence-post production, with grazing by cattle and goats preventing regeneration of most of the woody plants. The *mata-de-cipó* woodlands of Bahia (Brazil) harbour a high proportion of endemic and threatened species, yet they remain unprotected; establishment of one or more reserves with this habitat (preferably in Jequié-Boa Nova region) should be given high priority. In addition to preserving some of Brazil's most threatened endemics, creation of such reserves would have added benefit of protecting large populations of more common dry-habitat birds such as present species.

**Bibliography.** Cory & Hellmayr (1924), Gonzaga (2001), Gonzaga & Pacheco (1990), Hayes (1995), Hellmayr (1909b), Isler & Whitney (2002), do Nascimento *et al.* (2000), Olmos (1993), Perry *et al.* (1997), Rensen *et al.* (1986), Sick (1955, 1993, 1997), Stotz *et al.* (1996), Zimmer (2003a, 2003b).

## 120. Rusty-backed Antwren

### *Formicivora rufa*

**French:** Grisin roux **German:** Zimtrücken-Ameisenfänger **Spanish:** Hormiguero Dorsirrufo

**Taxonomy.** *Myiothera rufa* Wied, 1831, interior of Bahia, Brazil.

Morphological, vocal and molecular studies indicate that, with exception of *F. iheringi*, all species placed in current genus form a well-defined group. According to recent extensive morphological and vocal study, present species is closest to *F. grisea* and *Stymphalornis acutirostris*; close relationship to former also supported by genetic study. Plumage variation occurs within races as currently defined, and nominate race and *chapmani* possibly intergrade; also, possible regional variation in vocal repertoires; further study needed. Three subspecies recognized.

#### Subspecies and Distribution.

*F. r. urubambae* J. T. Zimmer, 1932 - E Peru (locally on E foothills of Andes in San Martín and Cuzco).

*F. r. chapmani* Cherrie, 1916 - S Surinam and EC Brazil (locally in Amapá, Pará, Maranhão and Piauí).

*F. r. rufa* (Wied, 1831) - SC & E Brazil (S Amazonas and extreme E Acre E to C Mato Grosso and Goiás, and from coastal Pernambuco, S to Mato Grosso do Sul and N São Paulo) S to extreme SE Peru (extreme E Madre de Dios), E Bolivia (Beni, La Paz, NE Cochabamba, Santa Cruz), and C & NE Paraguay (locally along R Paraguay and in N Amambay).

**Descriptive notes.** 12-13 cm; 11.5-14 g. Male has white supercilium, tawny-rufous crown and upperparts, outer scapulars edged white, concealed white interscapular patch; wings brownish-black, remiges (especially tertials) edged tawny-rufous, coverts mostly tipped white (buffish in some parts of range); graduated tail black fringed chestnut, with white sides and small white tips; head side, throat and central underparts black, white of supercilium extending as a line to breast side and broadening on belly side, posterior belly white, flanks and crissum cinnamon-buff; underwing-coverts white. Female is somewhat paler above than

male, hidden white interscapular patch reduced or absent, head side streaked black and white, whitish below with heavy black streaks, flanks, rear belly and crissum cinnamon. Subadult male resembles female, but throat and breast feathers appearing spotted, rather than streaked. Race *chapmani* female has much heavier streaking on underparts, especially throat, and tail tends to be more extensively black; *urubambae* female is intermediate, nearest to previous. **VOICE.** Typical loudsong a long (e.g. 34 notes, 2-3 seconds) rattle of evenly pitched harsh or sharp notes, often increasing in intensity, sometimes slightly longer initial note, note shapes appear to vary geographically; another vocalization resembling a loudsong is a series of sharp notes, slowly but irregularly delivered (e.g. 17 notes, 9-8 seconds), clearer and higher-pitched than preceding, possibly given only in some regions. Common call of an explosive or strident "chip cheep" or "tit-tweep", second note longer; notes from call, also from loudsong, sometimes delivered singly or in short countable series; rattle given in short (e.g. 0-3 seconds) bursts, repeated in quick succession.

**Habitat.** Occupies undergrowth of variety of habitats, including *cerrado* brushland, grassy *campos* with scattered trees and shrubs, white-sand forest, low seasonally wet grassland, and second-growth scrub; lowlands, to 1450 m in Andean foothills in Peru and Bolivia. Where syntopic with *F. grisea*, appears to occupy more open habitats.

**Food and Feeding.** Little published. Feeds on various insects, probably also spiders; stomach contents of single specimen from Brazil (Goiás) included hemipterans and coleopterans. Closely associated pair-members, individuals, or family groups forage mostly 0-2 m above ground, occasionally to 5 m; alone, or sometimes with mixed-species groups of other insectivores. Active forager, progressing by short hops and fluttery flights, separated by frequent pauses of 0-5-4 seconds to scan for prey. Usually hitches from side to side with each hop, working its way up through interior of shrubs, small trees and bunch-grass in zigzag progression before flying down to base of next shrub; posture generally horizontal, cocks half-fanned tail at c. 10 degrees above plane of body, and commonly swings it from side to side while simultaneously shallowly flicking partially drooped wings. Perch-gleans prey from tops and bottoms of live leaves, stems (both woody and herbaceous), seedheads and inflorescences, and large-bladed grass stems, by reaching up, out or down with quick stabbing motions of the bill, or by short, horizontal lunges; also makes frequent short (15-30 cm) sallies to glean prey from underside of overhanging vegetation; occasionally probes grass sheaths with its bill. Small prey immediately swallowed; larger items bashed repeatedly against branches before being consumed; wipes bill on branch after consuming prey. Not known to follow army ants.

**Breeding.** Sept-Jan in Brazil. One described nest, from São Paulo (Brazil), a deep, thinly woven cup with external diameter 7 × 6 cm, internal diameter 6 × 4 cm, depth 4-8 cm, outside height 7 cm, composed of light-coloured grass stems (through which contents visible), attached by rim 19 cm above ground in fork of small twig in small bush, and concealed by overarching frondlet of small ground palm amid dense but low mixture of grasses and small bushes. Clutch was 2 eggs, white, speckled brown around middle; incubation shared by both parents during day, probably only by female at night (this not established), incubation period not known; both also brooded and fed nestlings, which fledged on eighth day after hatching; adults believed to have re-nested soon after, fledging three young; young evidently stay with parents almost until next breeding season.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its extensive but patchy range. Regions inhabited include a number of protected parks and reserves, e.g. Chapada dos Guimarães, Chapada Diamantina, Sete Cidades, Pantanal Mato-grossense and Araguaia National Parks, in Brazil. As this species occupies a number of different habitats, including second-growth scrub, it is considered less vulnerable to disturbance than are most thamnophilids.

**Bibliography.** Bates *et al.* (1999), Cherrie (1916a), Cintra & Yamashita (1990), Cory & Hellmayr (1924), Davis (1993), Ericson & Amarilla (1997), Foster *et al.* (1994), Gonzaga (2001), Hackett & Rosenberg (1990), Haverschmidt & Mees (1994), Isler & Whitney (2002), Killen & Schulerberg (1998), Motta-Júnior (1990), Motta-Júnior & Vasconcello (1996), Naka *et al.* (2000), Naumburg (1930, 1939), Novas (1992), Parker (1989), Parker & Bailey (1991), Pearce-Higgins (2000), Peixoto Velho (1932), Ridgely & Tudor (1994), Sanaiotti (1986), Sick (1993, 1997), da Silva & Oniki (1988), da Silva *et al.* (1997), Sneath (1913), Stotz *et al.* (1996), Straube & Bormschein (1995), Tubelis & Tomás (1999), Willis & Oniki (1988b), Zimmer, J.T. (1932c), Zimmer, K.J. (2003a).

## 121. Black-hooded Antwren

*Formicivora erythronotos*

French: Grisin à dos roux

Spanish: Horniguerito Encapuchado

German: Schwarzkopf-Ameisenfänger

Other common names: Hooded Antwren

**Taxonomy.** *Formicivora erythronotos* Hartlaub, 1852, Brazil.

Morphological, vocal and molecular studies indicate that, with exception of *F. theringi*, all species placed in current genus form a well-defined group. Following its original description, present species was transferred to genus *Myrmotherula*; after long period with no records, species was rediscovered, and information on vocalizations and ecology strongly indicated that it should be returned to its present genus, a conclusion supported by recent extensive morphological and vocal study. Monotypic.

**Distribution.** SE Brazil in extreme E São Paulo and S Rio de Janeiro.

**Descriptive notes.** 11 cm. Male has deep rufous upperparts; otherwise, plumage mostly black, except wing-coverts thinly tipped white, white flanks. Female has black replaced by olive-brown, paler and buffier on underparts; variable amount of scattered, fine dark streaking or mottling on head and throat. Voice. Loudsong a dry rattle resembling that of *F. grisea*, but pace faster (e.g. 17 notes, 2-6 seconds). Common calls include soft "chep-ep", and explosive, nasal descending note that is often doubled.

**Habitat.** Variety of scrubby and regenerating habitats and second-growth woodland in

coastal plain; typically in young second growth, but also in secondary forest. Rediscovery site was in a swampy patch of secondary forest bordering mangroves; later found in nearby dry secondary forest. More recently, has been found in overgrown, abandoned banana plantations regenerating to secondary woodland, these areas having variably open understorey with numerous banana plants and viny thickets, and relatively uniform canopy of 3-5 m, with scattered emergent trees to 20 m; light-gaps in understorey dominated by smaller shrubs. Also occurs in lush understorey of modified *restinga*. Early successional habitats are dominated by pioneer species, including *Lantana camara*, *Cecropia*, *Morus*, *Rubus*, *Vernonia*, and grasses. Has successfully colonized fields 2 months after burning, where little regenerating vegetation.

**Food and Feeding.** Little published. Feeds on insects and spiders; also apparently small frogs. Closely associated pair-members, individuals, or family groups forage mostly 0-3 m above ground, occasionally to 7 m; seldom, if ever, with mixed-species flocks. Active forager, progressing through tangles of vegetation by short hops, with pauses of 1 second or less between movements; follows zigzag course, often hitching from side to side while moving upwards or horizontally; habitually

flicks wings while foraging, flashing the white flanks; no habitual tail movements, although tail occasionally wagged sideways. Vast majority of attack manoeuvres are perch-gleans from all surfaces of green leaves (both large and small), woody branches, stems and vines, including frequently from dead herbaceous vines; dead leaves frequently scanned, but seldom manipulated. One individual spent much time less than 1 m above ground, gleaning prey from tops of bracken-ferns. Short (less than 0.3 m), diagonal, upward-directed sallies to undersides of green leaves also frequently employed. Sometimes hitches up clusters of hanging vines along larger tree trunks, gleaning mostly from vine surfaces, to heights of 7 m. Not known to follow army ants.

**Breeding.** Nests found mid-Aug to early Feb. Nest built by both sexes, a small cup with fragile walls, constructed mainly from rootlets and a plant fibre, decorated with bryophytes (of at least 7 species), attached by rim to twigs of herbaceous plants 29-94 cm off ground. Clutch 2 eggs, more rarely 1. pinkish-white, spotted blackish-brown mostly around blunt end; incubation period 13-15 days; both sexes brood and feed young, only female broods at night; at two nests, male apparently contributed slightly more of the food for chicks and brooded young 57% of daylight time; nestlings fed primarily small caterpillars, also variety of other arthropods, and once a small frog offered; nestling period 10-11 days. Probability at start of incubation that eggs will produce fledglings was 0.23.

**Movements.** Presumed resident.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Atlantic Forest Lowlands EBA. Known from c. 20 specimens from 19th-century, and unrecorded for more than 100 years, this species was feared extinct. Had been thought confined to mountain forests near Nova Friburgo, until rediscovered in Sept 1987 at sea-level near beach resort of Angra dos Reis, on S coast of Rio de Janeiro state; subsequently found at several sites on W side of Baía de Ribeira, all near sea-level; now believed that specimen records from Nova Friburgo were in error, and that the species has always been confined to coastal lowlands. Main localities are Ariró (density of 89 pairs/km<sup>2</sup>) and Vale do Mambucaba (156 pairs/km<sup>2</sup>), with smaller numbers recorded at Bracuí, Frade, São Gonçalo, Taquari and Barra Grande. As part of an intensive effort to understand the biology of this threatened species, 24 nests were located in S Rio de Janeiro. Appears capable of surviving in a variety of humid second-growth habitats, but total range estimated at only 130 km<sup>2</sup>, and global population thought to number 1000-2500 individuals. Development of the narrow coastal plain for tourism and beachside housing has been extensive, and threatens many patches of suitable habitat; also widespread clearance of habitat for pasture and for plantations of *Euterpe* palms, both of which provide unsuitable habitat. Such plantations have already reduced available habitat in Vale do Mambucaba. The species does occur in the buffer zone of Serra da Bocaina National Park, but has not yet been found in nearby reserves such as Cairuçu Environmental Protection Area, Tamoios Ecological Station and Tamoios Environmental Protection Area. Systematic surveys needed in order to locate any additional populations of this bird, so that establishment of appropriate protected areas can be instituted.

# Genus *STYMPHALORNIS*

Bornschein *et al.*, 1995

## 122. Marsh Antwren

### *Stymphalornis acutirostris*

**French:** Grisin des marais

**German:** Schilfrohr-Ameisenfänger

**Spanish:** Hormiguerito del Paraná

**Other common names:** Marsh Antbird, Parana Antwren

**Taxonomy.** *Stymphalornis acutirostris* Bornschein *et al.*, 1995. Balneário Ipararay, Paraná, Brazil. Recent extensive morphological and vocal study (completed subsequent to the organization of this chapter) suggested that species should be placed in genus *Formicivora*, being most closely related to *F. rufa* and *F. grisea*. Monotypic.

**Distribution.** SE Brazil in coastal Paraná and extreme NE Santa Catarina.

**Descriptive notes.** 14 cm; 10 g. Male has grey forehead, short, poorly defined whitish supercilium, whitish crescent below eye; crown and upperparts chestnut-olive; wings blackish, flight-feathers edged chestnut-olive, coverts blacker and boldly tipped white, sometimes tinged ochraceous; graduated tail black; side of head, throat, breast and belly lead-grey, often faint white grizzling on side of face and neck, flanks and crissum dark olive-brown. Female is like male, except throat and anterior underparts white, densely and broadly streaked black, lower underparts lighter. **Voice.** Loudsong consists of doublets of

abrupt notes, first note typically more intense and lower-pitched, repeated in slightly unevenly and variably paced series (e.g. 7-10 doublets, 5-6 seconds), second note sometimes repeated by itself. Calls are variable squealing notes ranging in length from slightly longer than those in song to c. 0.35 seconds.

**Habitat.** Littoral marshes dominated by *Typha domingensis* and *Scirpus californicus* and with other marsh vegetation (especially Asteraceae and Poaceae) such as grasses and woody shrubs; near sea-level. Also occupies riverine marshes, wet fields and mangrove swamps, all usually subject to periodic fluctuations in water levels.

**Food and Feeding.** Little known. Feeds on variety of arthropods. Closely associated pair-members, individuals, or family groups forage mostly 0.2 m above ground. Active, progressing by short hops and fluttery flights, separated by pauses of 1-2 seconds to scan for prey; posture mostly horizontal, but more diagonal when hitching upwards through reeds or vertical stems and branches; tail held partially cocked (c. 10 degrees above plane of body), both wings shallowly flicked. Generally keeps to cover of dense marsh vegetation, hence difficult to observe. Most prey perch-gleaned from grass, reed, stem and live-leaf surfaces, by reaching up, out or down with quick bill-stabbing motions, or by short, horizontal lunges; sometimes jump-gleans or makes short (less than 30 cm) sallies to underside of overhanging vegetation. Not known to follow army ants.

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** ENDANGERED. Locally fairly common. Only recently discovered and, although not uncommon in appropriate habitat, has a tiny range, estimated at 1850 km<sup>2</sup>, and threatened by inherent vulnerability of its marshland habitat. First found in 1995, in lower third of R Guaraguaçu and R Nhundiaquara, in Parnaguá Bay; subsequently found in several areas of Matinhos and Guaratuba municipalities in Paraná, and also in São Francisco Bay in Garuva, Santa Catarina. Stronghold probably Guaratuba Bay, where it is known from Ilha do Chapeu, Chapeuzinho, and lower thirds of the São João, Cubatão, São Joãozinho, Descoberto, Boguaguçu, Preto, Paraná and Alegre rivers. All populations restricted to small patches or narrow tracts of habitat, some of which, including the type locality, are under extreme human pressure, and have been reduced by fires, landfills, agricultural development, cattle grazing, and invasive vegetation (especially *Bracharia*). Many small marshes in extreme SE Paraná (near Garuva) each held 1-3 pairs as recently as Nov 2001. Surrounding region, however, supports intensive, large-scale agricultural production, particularly of rice and bananas; in many cases, the various marshes inhabited by this species are encircled by cultivated lands, and could quite conceivably soon be converted to rice production. Immediate action to protect key sites, especially in Guaratuba Bay, is required. Additional intensive surveys needed in order to determine the distributional limits of this species.

**Bibliography.** Bornschein & Reinert (1996, 1997b), Bornschein *et al.* (1995), Gonzaga (2001), Isler & Whitney (2002), Naka *et al.* (2000), Reinert & Bornschein (1996, 1998), Stattersfield & Capper (2000), Zimmer (2003a).

# Genus *DRYMOPHILA* Swainson, 1824

## 123. Ferruginous Antbird

### *Drymophila ferruginea*

**French:** Grisin rouilleux

**German:** Rostbauch-Ameisenfänger

**Spanish:** Tiluchi Herrumbroso

**Taxonomy.** *Myiothera ferruginea* Temminck, 1822, vicinity of Rio de Janeiro, Brazil.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species closely related to *D. rubricollis*, until recently treated as conspecific. Monotypic. **Distribution.** SE Brazil, from SE Bahia S to NE Santa Catarina, extending inland to EC Minas Gerais and W São Paulo.

**Descriptive notes.** 12-13 cm; 9.5-11.5 g. Male has black crown, long white supercilium, broad black band through eye; lower side of head white, speckled black; upperparts reddish yellow-brown, centre of back black with some white of interscapular patch showing, rump rufous; wings brownish-black, remiges edged buffish, coverts broadly tipped white; graduated tail black, broadly tipped white; chin white, speckled black, throat and remaining underparts rufous. Distinguished from very similar *D. rubricollis* by black on back, somewhat darker remiges, darker rufous underparts, blacker tail shorter on average. Female is generally paler than male, especially below, crown streaked olive, wing-covert tips tinged rufous, no white interscapular patch. Subadult male resembles female, but forehead and crown feathers broadly margined pale buff, supercilium tinged buff, underparts paler, white interscapular patch. **Voice.** Male loudsong 2 rich notes with little space between, first note shorter, downslurred, more intense, second longer and more complex, ending upslurred; female loudsong similar notes, usually at slightly higher pitch, but repeated 2-4 times in rapid succession, typically starting as male ends his phrases. Calls include rich "chewp" and short, "chirring" rattle.

**Habitat.** Understorey and mid-storey of bamboo thickets in evergreen forest, from sea-level to 1250 m, occasionally to 1600 m. Found in primary forest, where bamboo often occurs along forest edge, or occupies treefall and landslide light-gaps; also in second-growth woodland, as well as in regenerating pure stands of bamboo. Often found with *D. ochropyga*; in some regions inhabits same bamboo thickets as *D. rubricollis* at 800-1200 m, but in others the two appear to be elevationally parapatric, and for most part they do not occur in same places; also occasionally with *D. genei*, but occurs mostly below elevations occupied by that species.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae and orthopterans; probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 1-10 m above ground, alone or with mixed-species flocks of other insectivores; mean foraging height in almost 250 observations was 4.1 m. Active forager; progresses by short hops, separated by pauses of 1-3 seconds to scan; often clings laterally to vertical stems, and hitches from side to side as it moves. Forages mostly at interface of dense bamboo thickets and forest, particularly where climbing bamboo tangles and vines overtop understorey saplings, creating dense mats of foliage; concentrates activities in leafy arching crowns of bamboo, rather than along more open stems below; also commonly forages in low, dense thickets of young bamboo, densely leaved shrubs, and ferns. At higher elevations, obtains insects primarily from bamboo leaves (including dead ones) and stems; at lower elevations, forages at least as frequently in dead leaves and live leaves of species other than bamboo. Perch-gleans from live leaves (particularly their undersides) or stems, by reaching up, out or down with quick stabs of the bill or by short, horizontal lunges; also makes short (less than 30 cm) fluttering sallies to glean prey from underside of overhanging vegetation. Commonly inspects small dead leaves trapped in branchlets and clusters of bamboo stems, and probes at nodes where bamboo spines trap leaf litter; frequently pulls and tears at suspended dead leaves with its bill, but rarely spends more than 2-3 seconds at any one leaf; also observed to work methodically through patches of dead ferns and glean items from stems and curled leaflets of the fronds. Not known to follow army ants.

**Breeding.** Little known. Season Oct-Feb, based on observations of food-carrying adults, young following adults, and single described nest under construction. Nest was pendent, composed of mossy strands, placed 1 m up in fork in compound fern leaf. Clutch size not known; eggs white, with irregularly distributed reddish-brown speckles, blotches and lines, either throughout or concentrated at larger end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Common throughout much of its range. Range includes several large protected areas, e.g. Serra da Bocaina, Serra dos Órgãos and Itatiaia National Parks, Augusto Ruschi Biological Reserve, Caraça National Park and Serra do Mar State Park. Enforced protection of all existing parks and reserves should ensure continued viability of this species. Its ability to utilize second-growth habitats may render it less vulnerable to disturbance than are most other antbirds.

**Bibliography.** Cândido (2000), Cory & Hellmayr (1924), Davis (1945, 1946), Ferreira de Vasconcelos & Melo-Júnior (2001), Goerck (1999a, 1999b), Ihering (1900), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Leme (2001a), Machado (1999), Parker (2003a), Parker & Goerck (1997), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Teixeira *et al.* (1989), Wilkinson & Smith (1997), Willis (1988a), Zimmer (2003a).

## 124. Bertoni's Antbird

### *Drymophila rubricollis*

**French:** Grisin de Bertoni

**German:** Zimtbauch-Ameisenfänger

**Spanish:** Tiluchi Colorado

**Taxonomy.** *Formicivora rubricollis* W. Bertoni, 1901, Puerto Bertoni, Alto Paraná, Paraguay. Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species closely related to *D. ferruginea*, and until recently treated as conspecific. Monotypic. **Distribution.** SE Brazil (extreme SE Minas Gerais, Rio de Janeiro and C & E São Paulo S to W & C Paraná and NW Rio Grande do Sul), E Paraguay (Canendiyu, Alto Paraná, Caazapá) and extreme NE Argentina (N Misiones).

**Descriptive notes.** 12.5-13.5 cm; 1 individual 10 g. Male has black crown, long white supercilium, broad black band through eye; lower side of head white, speckled black; upperparts reddish yellow-brown, few black feathers on back, white interscapular patch, rump rufous; remiges brownish-black, edged paler, wing-coverts black, broadly tipped white; graduated tail dark brown to blackish-brown, broad white tips; chin white, speckled black, throat and remaining underparts rufous. Distinguished from very similar *D. ferruginea* by having only few black feathers on back, somewhat paler remiges, paler underparts, browner tail longer on average. Female is paler than

male, forehead and crown rufescent brown, this reduced to streaks on hindcrown, wing-covert tips tinged rufous, no white interscapular patch. Subadult male is like female, but with white interscapular patch. **VOICE.** Male loudsong a short series (e.g. 9 notes, 1-7 seconds) but length variable, introductory note followed by shorter, sharper note that gradually lengthens into longer harsher notes while descending slightly in pitch, intensifies initially and also softens at end; female song lower-pitched, similar in pattern to male, but intermediate notes shorter and faster in greater contrast to final long, raspy notes, also usually less intense

than male song, and first note often overlaps last note of male's. Calls include long (e.g. 0.2 seconds), somewhat harsh and complaining notes in short series of 4-6, also similar but harsher and longer (e.g. 0.3-0.4 seconds) notes in triplets.

**Habitat.** Understorey and mid-storey of bamboo thickets in montane and lowland evergreen forest; at low elevations down to near sea-level in S, restricted to higher levels, from c. 900 m to 2000 m, in N. Perhaps less confined to bamboo in S end of range. In N of range, sometimes found in same bamboo stands as *D. ochropyga*, *D. genei* and *D. ferruginea*, depending on elevation; co-occurs with last in some regions, but in others the two appear to be elevationally parapatric, and in general they do not occur in same places.

**Food and Feeding.** Little published. Feeds on insects, including lepidopteran larvae and orthopterans; probably also on spiders. Closely associated partners, individuals, or family groups forage mostly 1-15 m above ground, alone or with mixed-species flocks of other insectivores; mean foraging height in over 200 observations was 3-9 m. Active forager; progresses by short hops, separated by pauses of 1-3 seconds to scan for prey. Appears to forage almost exclusively in bamboo, and only occasionally ventures into adjacent broadleaf trees or shrubs in N portion of range; hitches from side to side along arching bamboo stems; posture mostly horizontal, with tail held at same plane or slightly cocked, often swung from side to side and occasionally flicked up to 10-20 degrees above horizontal, then slowly lowered; habitually flicks both wings. Most attack manoeuvres are perch-gleans to live bamboo leaves, or suspended dead leaves trapped in the bamboo; gleans mostly by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; also makes short (less than 30 cm) fluttering sallies to underside of overhanging vegetation. Not known to follow army ants.

**Breeding.** In Brazil, nest found in Nov in Rio de Janeiro (Itatiaia) and female carrying food to concealed fledgling in Jan in São Paulo. Single known nest (details previously unpublished) was a small pendent cup/bag situated in fork of two intersecting thin stems of bamboo (*Merostachys*), concealed on all sides and above by bamboo leaves, near top of dense stand on steep hillside under broken-canopy forest (steep slopes prevented close examination); singing adults carrying food to nest.

**Movements.** Presumed resident; possibly some periodic local movements in response to major die-offs of bamboo.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Atlantic Forest Lowlands EBA. Fairly common throughout much of its range. Region within which it occurs contains several protected areas, e.g. Aparados da Serra, Iguaçu, Itatiaia and Serra dos Órgãos National Parks, in Brazil, and Iguazú National Park and Uruguá-i Provincial Park, in Argentina. May undergo periodic population fluctuations at local level coincident with major die-offs of bamboo. Enforced protection of all existing parks and reserves in which this species occurs should ensure its continued viability.

**Bibliography.** Belton (1985), Ferreira de Vasconcelos & Melo-Júnior (2001), Goerck (1999b), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Leme (2001a), Lowen *et al.* (1997), Pacheco & Laps (2001), Parker & Goerck (1997), Ridgely & Tudor (1994), Sick (1993, 1997), Stotz *et al.* (1996), Whitney (2003b), Willis (1988a), Zimmer (2003a)

## 125. Rufous-tailed Antbird

### *Drymophila genei*

**French:** Grisin à queue rousse **German:** Rostschwanz-Ameisenfänger **Spanish:** Tiluchí Colirrufo

**Taxonomy.** *Formicivora Genei* de Filippi, 1847, Brazil.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species most closely related to *D. ochropyga*. Monotypic.

**Distribution.** SE Brazil in SE Minas Gerais, S Espírito Santo, NE São Paulo and Rio de Janeiro.

**Descriptive notes.** 13-14 cm. Male has black crown, long white supercilium, black band through eye; lower side of head white, speckled black; back olive-brown, spotted black, white interscapular patch often apparent, rump and tail rufous; flight-feathers rufous, wing-coverts black, tipped white; throat and anterior underparts white, spotted black, spots heaviest on breast, unspotted rufous-brown flanks and crissum. Female has crown and nape rufous-brown, streaked blackish, weak supercilium whitish, line through eye dark brown, upperparts, wings and tail like male except no black spots on back, no white interscapular

patch; head side, throat and underparts buff, faint dark marks anteriorly. **VOICE.** Male loudsong a sharp note followed rapidly by long raspy notes on same pitch (e.g. 5 notes, 1-8 seconds); female lower-pitched, 3 distinct whistles followed by 2 weak rapidly delivered notes (e.g. 5 notes, 1-3 seconds). Calls include flat, thin, somewhat high-pitched, short (e.g. 0.15-0.2 seconds) notes in groups of 3-6 and similar groups of longer (e.g. 0.3-0.5 seconds) raspy "chirrs", closely spaced.

**Habitat.** Understorey of bamboo thickets in montane evergreen forest, occasionally in adjoining vine tangles and dense foliage; mostly 1150-2200 m, occasionally to 800 m. Often in same bamboo thickets as *D. rubricollis*, and replaced in similar habitat at lower elevations by *D. ochropyga* and *D. ferruginea*; all four species sometimes occur together in bamboo thickets between 1150 m and 1300 m.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated partners, individuals, or family groups forage mostly 0-3 m above ground, rarely to 7 m; mean foraging height in 278 observations was 1-5 m. Alone, but sometimes briefly joins mixed-species flocks of other insectivores as these pass through its territory. Active forager; progresses on zigzag

course by short hops, separated by frequent pauses of 1-2 seconds to scan; somewhat erratic, hitches from side to side, abruptly changes direction, frequently retraces routes. Forages both in bamboo and in nearby vine tangles overtopping shrubbery and small saplings, as well as in interior of shrubby thickets. Most attack manoeuvres are perch-gleans, primarily to vine and bamboo stem and leaf surfaces, but almost equally as often to suspended dead leaves and live leaves of broadleaf plants; gleans from vines, stems and live leaves (mostly undersides) by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; sometimes hangs head first to glean items from tops of lower leaves. Delicately probes curled tips of suspended dead leaves with its bill; also probes dead leaves trapped in nodes and bases of spine clusters of bamboo. Rarely follows army ants; one pair briefly visited swarm of *Labidus praedator* at 1700 m in Itatiaia National Park (Rio de Janeiro).

**Breeding.** Nothing known.

**Movements.** Presumed resident; possibly some periodic local movements in response to major die-offs of bamboo.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Locally common in several protected areas, e.g. highlands of Itatiaia, Serra dos Órgãos and Serra da Bocaina National Parks. Has a tiny range and specialized habitat requirements; populations should therefore be monitored. Enforced protection of all existing parks and reserves in which this species occurs should ensure its continued survival. Episodic large-scale die-offs of bamboo may result in periodic fluctuations in local populations of this and other bamboo specialists.

**Bibliography.** Collar *et al.* (1994), Cory & Hellmayr (1924), Goerck (1999a, 1999b), Holt (1928), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Luderwaldt (1909), Parker (2003a), Parker & Goerck (1997), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Willis (1985a), Zimmer (2003a).

## 126. Ochre-rumped Antbird

### *Drymophila ochropyga*

**French:** Grisin à croupion ocre **German:** Ockerbüzel-Ameisenfänger **Spanish:** Tiluchí Culipardo

**Taxonomy.** *Formicivora ochropyga* Hellmayr, 1906, Ipanema, São Paulo, Brazil.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species most closely related to *D. genei*. Monotypic.

**Distribution.** SE Brazil from C & SE Bahia, E Minas Gerais and Espírito Santo S to E São Paulo, E Paraná and E Santa Catarina.

**Descriptive notes.** 12.5-13.5 cm. Male has black crown, long white supercilium, black band through eye; lower side of head white, speckled black; back grey, few central feathers black and white, white interscapular patch often apparent, rump light rufous; wings blackish, remiges thinly edged buffish, coverts broadly tipped white; graduated tail black, tipped white; throat and anterior underparts white, streaked black, streaks heaviest on breast, unmarked rufous flanks and crissum. Female differs from male in buff-streaked crown, olive-grey back, duller underparts less heavily streaked and more extensively buff.

**VOICE.** Male loudsong a short, rich flat note immediately followed by a long, higher-pitched raspy note; female lower pitched, 4 evenly spaced notes dropping slightly in pitch, followed by 2 raspy notes of which second resembles long second note of male song (e.g. 6 notes, 2-2 seconds). Common call a series of 3-5 evenly paced, piercing, sharp notes.

**Habitat.** Understorey of dense bamboo thickets and vine tangles in montane evergreen forest, locally also in lowland evergreen forest; 300-1950 m. Overlaps with *D. ferruginea* and, at upper end of elevational range, with *D. genei* and *D. rubricollis*.

**Food and Feeding.** Little published information available. Feeds on variety of insects and spiders; seen taking white egg sac, probably of spider. In one study, commonest arthropods collected from dead leaves, the species' primary feeding site, were spiders, beetles (Coleoptera), cockroaches (Blattellidae), Orthoptera, and woodlice (Isopoda). Closely associated pair-members, individuals, or family groups forage 0-3 m above ground, rarely higher; mean foraging height in over 200 observations was 1-7 m, and in another case median height of 23 observations was 0-3 m. Alone, or sometimes in mixed-species flocks of other insectivores as these pass through its territory. Active forager, progressing by short hops, with frequent pauses of 1-3 seconds to scan for prey; posture mostly horizontal; partially fanned tail often flicked rapidly up to 10 degrees above plane of body, then slowly flexed downwards, and both wings habitually flicked. Somewhat erratic in its movements, follows zigzag course and hitches from side to side with each hop, with abrupt changes of direction and frequent retracing of routes; sometimes jumps briefly to the ground as it makes its way. Forages in dense stands of bamboo, both in shaded, more mature stands and in younger successional stages in light-gaps, also in nearby shrubby vine tangles. Most attack manoeuvres are perch-gleans, great majority of these targeted at dead leaves, e.g. 55% of 213 observations in one study; of 139 observations of perch-gleaning in another study, 70% were at dead leaves, most of remainder at twigs and bamboo nodes (19%), and very few at live foliage (7%). In one study, over half of dead leaves attacked were bamboo, about one quarter were curled leaves, and remainder were ferns. Gleans most prey items by reaching up, out or down with quick stabs of the bill, or by short, horizontal lunges; seldom hangs or sallies. Not known to follow army ants.

**Breeding.** Almost nothing known. Eggs white, irregularly speckled, blotched and lined with red-brown, markings all over or concentrated at larger end.

**Movements.** Presumed resident; possibly some periodic local movements in response to major die-offs of bamboo.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Atlantic Forest Mountains EBA. Locally fairly common. Occurs in several protected areas, e.g. Serra dos Órgãos, Itatiaia and Caraça National Parks, and Serra do Mar State Park. Has tiny range and specialized habitat requirements, and populations therefore should be monitored. Episodic large-scale die-offs of bamboo may result in periodic fluctuations in local populations of this and other bamboo specialists. Enforced protection of all existing parks and reserves in which this species occurs should ensure its continued viability.

## 127. Dusky-tailed Antbird

### *Drymophila malura*

**French:** Grisin malure **German:** Olivrücken-Ameisenfänger **Spanish:** Tiluchi Estriado Oriental

**Taxonomy.** *Myiothera malura* Temminck, 1825, Ipanema, São Paulo, Brazil.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Monotypic.

**Distribution.** SE Brazil (S Minas Gerais, S Espírito Santo and Rio de Janeiro S to E & S Paraná, Santa Catarina and N Rio Grande do Sul), SE Paraguay (Alto Paraná, Caazapá, E Paraguari, Itapúa) and NE Argentina (Misiones).

**Descriptive notes.** 13.5-14.5 cm; 11-13 g. Male has head and neck streaked black and whitish-grey, upperparts olive-grey, interscapular patch white with black feather tips; remiges brownish, wing-coverts blackish with white tips; graduated tail brownish-grey; throat and anterior underparts streaked black and white, flanks and crissum olive-brown. Female has crown, nape and side of neck heavily streaked dark brown and buff to olive-brown, head side finely streaked dark (foreface mostly unstreaked), pale buff crescents above and below eye; upperparts, including tail, warm brown, interscapular patch blackish-grey,

flight-feathers warm brown, edged rufous, wing-coverts contrastingly blackish, narrowly tipped white or pale buff; buff below, paling to almost whitish on chin and centre of belly, breast variably streaked with dark brown, heaviest on sides, faint in middle, vent and lower flanks rich ochraceous; axillaries white. **Voice.** Male loudsong a simple short (e.g. 2-3 seconds) series of abrupt emphatic notes that speed up into trill, dropping slightly in pitch and intensity at end; female loudsong shorter (e.g. 1-4 seconds), weaker, lower-pitched, 4-5 whistles slow down, drop in pitch, and lengthen into slur before abruptly ending in short higher-pitched trill. Calls include short (e.g. 0-2 seconds) thin, buzzy (modulated), somewhat high-pitched notes, repeated after short intervals, and harsher note with clearer ending.

**Habitat.** Understorey of lowland and foothill evergreen forest, forest edge, and second-growth woodland; to 1300 m, locally to 1900 m. Seems to require dense tangles or thickets of bracken-ferns, vines or bamboo, and at forest edges often with tall grass mixed in. Not so restricted to bamboo as some other members of genus, although can be found in clear-cuts that are regenerating with dense, young stands of bamboo and grass less than 2 m tall.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated partners, individuals, or family groups forage mostly 0-4 m above ground, occasionally to 8 m; mean foraging height in 195 observations was 1.9 m. Alone, or sometimes briefly joining mixed-species flocks as these pass through its territory. Active forager, progressing by short hops, separated by frequent pauses of 1-3 seconds to scan; posture generally horizontal; tail held slightly fanned, usually at level of body or cocked slightly above horizontal, and regularly dipped slowly 30 degrees before being flicked quickly upwards; both wings habitually flicked. Somewhat erratic in movements, follows zigzag course with abrupt changes of direction and frequent retracing of routes. Forages mostly in dense cover, including low viny thickets and leafy crowns of bamboo. Most prey perch-gleaned from tops and bottoms of live broad leaves, dead leaves, bamboo stems and internodes, and vines, by reaching up, out or down with quick stabs of the bill; sometimes jump-gleans or makes short (less than 30 cm) fluttering sallies to underside of overhanging vegetation; also lightly probes curled tips of suspended dead leaves with the bill. Not known to follow army ants.

**Breeding.** Little known. A nearly completed nest almost certainly of this species (the pair not actually seen on the nest) found in Sept in Brazil (Minas Gerais): an open cup measuring 8 × 6.5 cm, height 10.5 cm, made of dead bamboo leaves interwoven with green moss, seed stems and spider webs, supported between horizontal branches of bamboo 98 cm up in bamboo scrub 2-3 m tall. Eggs from other locations creamy yellow, covered with violet-brown and dull lilac-grey spots, most concentrated at blunt end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common; somewhat more patchily distributed than other members of the genus. Has less specialized habitat requirements than congeners, which should render it less vulnerable to disturbance; appears able to survive in large patches of more or less remnant forest. Occurs in several protected areas, e.g. Aparados da Serra, Iguacu, Serra da Canastra and Caraça National Parks, and the Serra da Graciosa highlands, in Brazil, and Iguazú National Park and Uruguá-i Provincial Park, in Argentina. Given its small range, monitoring of populations is recommended. Escarpment forests of N Rio Grande do Sul possibly a major stronghold for this species; protection of a significant block of these forests would benefit not only this species, but also a number of other regional endemics with even more restricted ranges.

**Bibliography.** dos Anjos (2001a), dos Anjos & Boçon (1999), Belton (1985), Bencke & Kindel (1999), Buzzetti (2003b), Cory & Hellmayr (1924), Ferreira de Vasconcelos & Melo-Júnior (2001), Ferreira de Vasconcelos *et al.* (1999), Fraga & Narosky (1985), Goerek (1999b), Isler & Whitney (2002), Leme (2001a), Machado (1999), Marini *et al.* (1996), Mazar Barnett & Kirwan (2001), Ridgely & Tudor (1994), do Rosário (1996), Schönwetter & Meise (1967), Scott & Brooke (1985), Sick (1993, 1997), Stotz *et al.* (1996), Zimmer (2003a).

## 128. Scaled Antbird

### *Drymophila squamata*

**French:** Grisin écaillé **German:** Bindenschwanz-Ameisenfänger **Spanish:** Tiluchi Escamoso

**Taxonomy.** *Myiothera squamata* M. H. K. Lichtenstein, 1823, Bahia, Brazil.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Genetic analysis indicates that race *stictocorypha* may be a separate species; possible differences in vocalizations and ecology remain to be investigated further. Geographical ranges based on plumage, but likely to be revised after other characteristics have been studied. Two subspecies currently recognized.

### Subspecies and Distribution.

*D. s. squamata* (M. H. K. Lichtenstein, 1823) - E Brazil in E Alagoas and E Bahia.

*D. s. stictocorypha* (Boucard & Berlepsch, 1892) - SE Brazil (E Minas Gerais, Espírito Santo, Rio de Janeiro, and E São Paulo S to extreme NE Santa Catarina).

**Descriptive notes.** 12-13 cm; 10.5-11.0 g. Male has black crown with white spots at side, broad white supercilium, black eyestripe; upperparts black, spotted white, wings black, wing-coverts broadly tipped white, tail black, barred white; head side, throat and underparts white, spotted black. Female is patterned like male, but upperparts dark brown and buff, flanks and crissum pale cinnamon. Race *stictocorypha* male typically differs from nominate in having spots on centre of crown, rear underparts darker grey, but these characteristics may overlap between races. **Voice.** Loudsong a series of 5-6 long notes with

shorter spaces between them, delivered in c. 3-5-4 seconds, notes frequency-modulated and unclear, intensity and pitch usually increasing and then decreasing, note shapes variable, typically initial note rises in frequency and remaining ones downslurred. Calls may vary regionally, include abrupt "pip", often repeated in doublet or rapidly 3-4 times, also short series of c. 4 notes on falling scale, and relatively high-pitched (e.g. 5-5 kHz), short (e.g. 0-6 seconds) rattle decreasing in pitch and intensity.

**Habitat.** Understorey of lowland and foothill evergreen forest and second-growth woodland, from sea-level to 900 m; in lowlands in S of range, but occurs higher in N (e.g. the only *Drymophila* found in highlands of Alagoas). In Serra da Ouricana (Bahia) also occurs in foothills with *D. ferruginea* and *D. ochropyga*, but those two species are restricted to bamboo thickets. The only member of genus not closely associated with bamboo, although degree of association may vary regionally. One study in coastal Bahia found nominate race to be a bamboo specialist, but is not associated with bamboo in foothills of Alagoas and Serra da Ouricana. Race *stictocorypha* often found in bamboo, but seemingly equally common in places that lack bamboo; in coastal lowlands of Rio de Janeiro and São Paulo, particularly common in poorly drained *Heliconia* thickets within forest and occurs in *restinga* woodland in sight of the ocean.

**Food and Feeding.** Little published. Feeds on variety of insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly 0-4 m above ground, sometimes to 6 m; mean foraging height in 267 observations was 2-3 m. Alone, or with mixed-species flocks of other insectivores. Active forager, progressing by short hops, separated by pauses of 0-5-2 seconds to scan for prey; maintains mostly horizontal posture, partially droops wings and habitually flicks them shallowly; clings laterally to slender vertical stems and vines, hitches its way up from side to side with each hop, or maintains single orientation for several consecutive hops before flitting to another stem or vine, eventually flies back down near ground and begins working its way back up. Forages in shaded interiors of trees, close to trunks with lots of hanging vines and philodendrons (*Philodendron*); also on or near ground in dense stands of broad-leaved herbaceous vegetation, and in shaded understorey with abundance of closely spaced, slender vertical stems. Works through fallen branches and mats of dead ferns, leaves and other organic debris on forest floor; also through mostly brown parts of bamboo thickets, and in crowns of understorey shrubs, palms and saplings. Forages along larger tree trunks by hitching up hanging vines, always within 30 cm of trunk, and gleaning from vine surfaces and leaves and petioles of philodendrons and other epiphytes. Most attack manoeuvres are perch-gleans to stem, vine and branch surfaces, less often to tops and bottoms of live leaves; gleans by reaching up, out or down with quick stabs of the bill, or by short, horizontal lunges; also makes frequent short (15-30 cm) sallies or hover-gleans, and even shorter jump-gleans to underside of overhanging vegetation; rarely scans or probes suspended dead leaves. Foregoing applies primarily to S populations. Nominative race in Alagoas seldom seen more than 0-3 m above ground, often hops on ground and makes jumping, nearly vertical sallies of 10-30 cm to undersides of large green leaves, almost in manner of an antipit (*Corythopis*); also hitches up slender vertical stems and over fallen branches like S birds. All populations sally-glean more than do other Atlantic Forest congeners; in one study, 68% of attack manoeuvres by nominate race were gleans and 29% were sallies, compared with 59% gleans and 39% sallies for race *stictocorypha*. Nominative race occasionally follows army ants (*Eciton burchelli*); in six recorded instances in Bahia, foraging attempts over ants were short sallies to leaves or pecks at leaves and vines, and birds did not linger over slow-moving ants but, instead, circled away from them repeatedly.

**Breeding.** Four nests found: in Alagoas in Oct, in SE Bahia in Dec, and in São Paulo in Nov (two). In São Paulo, one described as a basket, external diameter 7-6 cm, external height 5-5 cm, constructed from leaves and fibres, decorated sparsely with moss around rim, lined with fibres and roots, a long woven strip of thin leaves and fibres (c. 5 times as long as nest height) attached to rear of nest perhaps as camouflage or decoration, tied to two parallel horizontal branches 40 cm up in small bush in thin undergrowth of *restinga* woodland; the other measured 9 × 6-2 cm, height 8-7 cm, made with green moss, dead bamboo leaves and strands of *Marasmius*, with large dead leaves hanging from it, placed 47 cm above ground on horizontal fork in shrub in 20-m rainforest; nests in SE Bahia (Dec) and Alagoas (Oct) also placed on horizontal fork and made of dead leaves (of Cyperaceae), green moss and *Marasmius*, but apparently not decorated with leaves, respective sizes 8-2 × 6-8 cm and 8 × 8 cm, heights 8 cm and 7-5 cm, and built 52 cm and 1-91 m above ground. At São Paulo nest, clutch 2 eggs (one had hatched at time of discovery), whitish with brown blotches, in 1 day's observation male contributed 67% of food delivered and brooded young 60% of daylight time, female brooded at night; in Alagoas and SE Bahia, eggs white, covered with wine-coloured spots and vermiculations; other eggs described as whitish, with flecks noted variously as dark cherry-brown, brownish-red and blackish.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout most of its range. Regions in which species occurs include a number of protected areas, e.g. Murici Ecological Reserve, Sooretama Biological Reserve, Tijuca and Serra da Bocaina National Parks and Serra do Mar State Park. Probably most common at base of the Serra do Mar in lowlands of N São Paulo, particularly around Ubaituba; much of this area falls under the umbrella of Serra do Mar State Park, which, like many of the other Atlantic Forest reserves, would greatly benefit from more rigorous protection of its boundaries from hunters and wood-cutters. Continued protection of this park, and of other existing parks/reserves containing populations of this antbird, should ensure the long-term survival of the species.

**Bibliography.** Aleixo (1999), Buzzetti (2003b), Cory & Hellmayr (1924), Goerek (1999a, 1999b), Gonzaga *et al.* (1995), Isler & Whitney (2002), Lopes *et al.* (1980), Machado (1999), Marini *et al.* (1996), Mendonça (2000), Naka *et al.* (2000), Naumburg (1939), Parker (2003a), Parker & Goerek (1997), Pinto (1935), Ribon & Maldonado-Coelho (2001), Ridgely & Tudor (1994), Scott & Brooke (1985), Sick (1993, 1997), Stotz (1990b), Stotz *et al.* (1996), Teixeira *et al.* (1986), Willis (1985a), Zimmer (2003a).

## 129. Striated Antbird

*Drymophila devillei*

French: Grisin de Deville

Spanish: Tiluchi Estriado Occidental

German: Weißbauch-Ameisenfänger

**Taxonomy.** *Formicivora devillei* Menegaux and Hellmayr, 1906, north-east Peru; error = Cuzco, south-east Peru.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species most closely related to *D. caudata*. Recent genetic study indicated substantial differentiation between populations E & W of R Madeira, and possibility that more than one species involved. Two subspecies recognized.

**Subspecies and Distribution.**

*D. d. devillei* (Menegaux & Hellmayr, 1906) - SC Colombia (W Meta, W Putumayo), NE Ecuador (W Napo), SE Peru (Ucayali, E Cuzco, Madre de Dios), SW Amazonian Brazil (W of R Madeira in W Amazonas and Acre) and NW & C Bolivia (Pando, La Paz, Cochabamba).

*D. d. subochracea* Chapman, 1921 - SC Amazonian Brazil (E of R Madeira and R Mamoré in E Amazonas, Rondônia, W & N Mato Grosso and W Pará) and NE Bolivia (NE Santa Cruz).

**Descriptive notes.** 13-14 cm; 10-12 g. Male has crown and anterior upperparts black, streaked white, white interscapular patch, rump deep rufous; wings black, flight-feathers edged rufous, coverts tipped white; graduated tail black, white tips and intermediate spots; head side down to lower breast white, streaked black, throat and belly white, flanks and crissum rufous. Distinguished from similar *D. caudata* by no rufous tinge on back, blacker tail shorter and having intermediate spots, unstreaked throat, less heavy streaks below. Female is like male, except white of upperside other than tail replaced by light rufous-buff and black replaced by blackish-brown,

no interscapular patch, underside tinged rufous-buff, flanks paler. Juvenile is olive-grey above, tinged rufous posteriorly, white below, tinged buff, olive-grey breastband; subadult male resembles female. Race *subochracea* differs from nominate in more uniformly ochraceous buff to rufous-buff underparts, paler on throat and belly, ochraceous wing edgings, female also more ochraceous. **VOICE.** Male loudsong a moderately long series (e.g. 17 notes, 3 seconds), 2 weak introductory notes followed by 3 emphatic long raspy notes, then rapid accelerating series of clear notes rising and falling in pitch; race *subochracea* similar in pattern, but emphasized notes clear rather than raspy; female loudsong resembles male's but typically weaker, with emphasized notes coming later in series. Call a doublet, sometimes triplet, of moderately long (e.g. 0.1-3 seconds) whistles, also similar note but harsh in quality.

**Habitat.** Understorey and mid-storey of thickets of *Guadua* bamboo in lowland and foothill evergreen forest, to 1000 m. Apparently an obligate bamboo specialist; absent from areas lacking sufficient density of bamboo. Appears to prefer bamboo patches growing under, or surrounded by, trees.

**Food and Feeding.** Feeds on various insects, particularly lepidopteran larvae; probably also on spiders. Closely associated pair-members, individuals, or family groups forage mostly 5-10 m above ground, occasionally down to 2 m and up to 20 m; in Peru (Madre de Dios), mean height in 62 observations was 6.5 m and in 155 observations at a nearby site 6 m. Alone, or sometimes joining mixed-species flocks of other insectivores as these move through its territory. Forages actively, progressing rapidly by short hops, separated by pauses of 1-3 seconds to scan for prey; as it moves, habitually flicks both wings shallowly, wags tail up and down in shallow arc; somewhat erratic in movements, usually following zigzag course with abrupt changes of direction and frequent retracing of routes. Forages mostly in shaded crowns of bamboo and ambient vine tangles; hops rapidly along vines and horizontal limbs, hitches from side to side as it makes its way through horizontal perches and up vertical bamboo stalks. Most prey perch-gleaned from live bamboo leaves (mostly from undersides) and stems, vines, and clusters of bamboo spines, usually by reaching up, out or down with quick stabs of the bill, or by short, horizontal lunges; often makes short (less than 30 cm) fluttering sallies or jump-gleans to underside of overhanging vegetation. Regularly scans small, suspended dead leaves (mostly of bamboo); usually probes curled dead leaves delicately with its bill, sometimes tears apart small dead leaves to extract hidden prey. Not known to follow army ants.

**Breeding.** Little known. Female seen to enter apparently domed nest in bamboo; in Brazil, territory size at Cachoeira Nazaré (Rondônia) estimated at 0.3 ha, at Alta Floresta c. 0.5 ha.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Locally fairly common within its patchy range. Nominant race fairly common to common in some large protected areas in S portion of range, e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, and Serra do Divisor National Park, in Brazil, but rare and local in N. Race *subochracea* known from Noel Kempf Mercado National Park, in Bolivia, and Cristalino State Park, in Brazil, but large gaps exist between other known localities, and intervening regions either lack sufficient bamboo or, in some cases, have not been adequately surveyed; given the few sites from which this race is known, combined with its dependence on a specific and patchily distributed habitat, this taxon should be monitored for signs of decline.

**Bibliography.** Alverson *et al.* (2000), Bates *et al.* (1999), Cadena, Álvarez *et al.* (2000), Cory & Hellmayr (1924), Foster *et al.* (1994), Goerck (1999b), Goerck *et al.* (1998), Hackett & Rosenberg (1990), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Kratter (1997a), Kratter *et al.* (1992), Navarrete *et al.* (2002), Novaes (1976), Parker (1982, 2003a, 2003b), Remsen (2003b), Ridgely & Tudor (1994), Servat (1996), Sick (1993), Stotz (1990a), Stotz *et al.* (1996), Terborgh *et al.* (1984), Zimmer, J.J. (1931b), Zimmer, K.J. (2003a), Zimmer, K.J., Parker *et al.* (1997).

## 130. Long-tailed Antbird

*Drymophila caudata*

French: Grisin à longue queue

German: Langschwanz-Ameisenfänger

Spanish: Tiluchi Colilargo

**Taxonomy.** *Formicivora caudata* P. L. Slater, 1855, "Bogotá" = possibly west slope of east Andes, Colombia.

Members of genus form a well-defined clade, and appear to be closely related to *Hypocnemis*. Present species most closely related to *D. devillei*. Genetic analysis and geographical variation in vocalizations indicate that further study and redefinition of populations is still needed. Relationships among currently defined races unclear at N end of E Andes (Norte de Santander, in Colombia), where three races may be parapatric or may intergrade. Four subspecies currently recognized.

**Subspecies and Distribution.**

*D. c. klagesi* Hellmayr & Seilern, 1912 - N Venezuela (except Sierra de Perijá) and N Colombia (E slope of E Andes in S Norte de Santander).

*D. c. aristeguietana* Avelledo & Pérez, 1994 - NW Venezuela (Sierra de Perijá).

*D. c. hellmayri* Todd, 1915 - N Colombia (Santa Marta region and E slope of E Andes in N Norte de Santander).

*D. c. caudata* (P. L. Slater, 1855) - Andes of Colombia (except N end of E range on E slope), Ecuador (both slopes), Peru (E slope) and NW Bolivia (E slope in La Paz).

**Descriptive notes.** 14.5-15.5 cm; 11-13 g. Male nominate race has crown and anterior upperparts black, streaked white, back streaks tinged rufous, white interscapular patch, rump deep rufous; wings black, flight-feathers edged rufous, coverts tipped white; graduated tail blackish-grey, white tips; head side and throat down to lower breast white, heavily streaked black, belly white, flanks and crissum rufous. Distinguished from similar *D. devillei* by pale streaks on back tinged rufous, longer and paler tail lacking intermediate spots, streaked throat, more heavily streaked anterior underparts. Female differs from male

in having crown streaks cinnamon-rufous, other pale markings above (except on tail) light rufous-buff rather than white, black areas duller, no interscapular patch, underside tinged rufous-buff, flanks paler. Race *hellmayri* has tail dusky, tinged rufous, wide blackish subterminal bar, male rear central crown solidly black; *klagesi* is similar to previous, but centre of throat and breast with no or only faint spots, female flanks paler; *aristeguietana* reportedly differs from last in heavier streaking, lighter rufous coloration. **VOICE.** Typical male loudsong 2 short clear whistles followed by 2 long raspy notes, but number of each, also shape, length and quality of notes, vary regionally and individually; typical female loudsong a short series of whistles dropping in pitch, sometimes terminating in harsh note. Calls include variety of high-pitched (e.g. 5 kHz) short whistles, sometimes in abrupt pairs.

**Habitat.** Understorey and mid-storey of bamboo thickets (both native and introduced Asian species) in montane evergreen forest and secondary forest, mainly from 1200 m to 2500 m; mostly 800-1600 but occasionally down to 300 m in Venezuela, as low as 750 m in Ecuador, and as high as 2700 m in Colombia. Also away from bamboo in vine tangles, shrubby forest borders, and overgrown coffee fincas. Although less restricted to bamboo than are most congeners, is found more frequently in it than away from it.

**Food and Feeding.** Feeds on variety of insects, probably also spiders; stomach contents included lepidopteran larvae and a small beetle (Coleoptera). Closely associated pair-members, individuals, or family groups forage mostly 1-15 m above ground; alone or, sometimes, with mixed-species flocks as these pass through its territory. Active forager, progressing by short hops, with pauses of 1-3 seconds between movements to scan for prey. In most areas, forages primarily in bamboo, hitching from side to side up vertical stems to crowns, where bamboo foliage, vines and upper branches of understorey trees form interlacing mats or sprays of foliage; also in densely foliated shrubs, thickets and hillside stands of bracken-fern. Perch-gleans most prey from live and dead bamboo foliage, stem surfaces, nodes and clusters of spines, by reaching up, out or down with quick stabs of the bill, or by short, horizontal lunges; frequently jump-gleans or makes short (less than 30 cm) fluttering sallies to underside of overhanging vegetation; when gleaning from bamboo leaves or from broad-leaved plants, most often takes items from undersurface. Not known to follow army ants.

**Breeding.** Almost nothing known. Breeding reported in Jun in Venezuela; season likely to vary across extensive range.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common but locally distributed throughout range. Occurs in several protected areas, e.g. Munchique National Park and La Planada Nature Reserve, in Colombia. The ability of this species to utilize some second-growth habitats may render it less vulnerable than other members of the genus.

**Bibliography.** Avelledo & Pérez (1994), Bates *et al.* (1999), Cory & Hellmayr (1924), Ejlsd & Krabbe (1990), Goerck (1999b), Goerck *et al.* (1998), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee (1966), Meyer de Schauensee & Phelps (1978), Parker & Carr (1992), Ridgely & Tudor (1994), Schäfer & Phelps (1954), Schulenberg & Awbrey (1997a), Stotz *et al.* (1996), Thomas (1993), Zimmer, J.T. (1931b), Zimmer, K.J. (2003a).

PLATE 58

Family THAMNOPHILIDAE (TYPICAL ANTBNRDS)  
SPECIES ACCOUNTS

Genus *TERENURA* Cabanis & Heine, 1859

131. Streak-capped Antwren

*Terenura maculata*

French: Grisin à tête rayée German: Rostrücken-Ameisenfänger Spanish: Tiluchi Enano

**Taxonomy** *Myiothera maculata* Wied. 1831, no locality - Rio de Janeiro, Brazil. Forms a superspecies with *T. sieki*; further analysis of molecular, vocal and other characteristics that may differentiate them is needed. Monotypic.

**Distribution** SE Brazil (coastal region from SE Bahia S to Santa Catarina, inland locally in S Minas Gerais, São Paulo and Paraná), E Paraguay (Canendiyu S to Caazapa) and extreme NE Argentina (Misiones).

**Descriptive notes** 9-10 cm; 1 individual 6.5 g. Male has crown to upper back streaked black and white; remaining upperparts tawny, mixed with yellow posteriorly, hidden white patch under scapulars; wings black, flight-feathers edged pale yellow, tertials edged tawny, coverts broadly tipped white

(sometimes tinged yellow); tail olive-grey; throat and upper breast white, streaked black, lower breast yellow, streaked black, posterior underparts yellow. Female is like male but paler, white on head and throat tinged pale buff, underpart streaking less distinct. **VOICE.** Loudsong a long (e.g. 3.8 seconds) dry rattle gaining in intensity at beginning, generally (but unevenly) rising in pitch. Calls include sharp "chip" and slightly longer, lower-pitched downslurred note, each delivered singly or in short series of 3-5, or the two often combined in distinctive lengthy series and either alternating or one note alternating with two of the other.

**Habitat.** Canopy and mid-storey of evergreen forest and second-growth woodland, from sea-level to 1250 m.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated partners, individuals, or family groups forage mostly from 6 m above ground to the canopy, sometimes down to ground; often lower than congeners, particularly at forest edge and in second-growth woodland (including overgrown, regenerating banana plantations). Either alone or, more often,

with mixed-species flocks of other insectivores; this species and *T. sicki* are less habitual flock-followers than are other congeners. Very active, restless forager, progressing by short hops, seldom pausing for more than 1 second to scan for prey; forages in dense, small foliage in crowns of trees and, especially, in masses of vine tangles along trunks and overtopping understory trees, also in mats of vegetation formed by interlaced crowns of arching bamboo (*Merostachys*). Perch-gleans most prey from tops and bottoms of live leaves, leaf petioles, stems, and vine surfaces, by reaching up, out or down with quick stabs of the bill, or by short, horizontal lunges; acrobatically hangs head first or upside-down, often from leaf margins in manner of a greenlet (*Hylophilus*), to glean from upper surface of lower leaves; also makes occasional short (less than 40 cm) hover-gleans or sallies to underside of overhanging vegetation. Regularly scans suspended dead leaves, probes curls lightly with its bill, but does not otherwise manipulate the leaf, and more often ignores dead leaves altogether. Not known to follow army ants.

**Breeding.** Nest found in Oct in Brazil (above Camaça, in Bahia; details previously unpublished): a small, pendent cup/bag, c. 5 cm deep, 2-5 cm across, paler than surrounding leaves which hid it, placed 5 m above ground in fork near end of thin branch of tree c. 9 m tall at edge of disturbed forest on steep slope; adult video-taped as it took food to nest. Clutch size not documented; eggs covered with dark brown and lilac-grey spots, ground colour uncertain.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout most of its range. Region inhabited includes several protected parks and reserves, e.g. Itatiaia, Tijuca, Iguaçu, Serra da Bocaina and Serra dos Órgãos National Parks, Augusto Ruschi and Sooretama Biological Reserves and Serra do Mar State Park, in Brazil, and Iguazú National Park in Argentina. Not reliant on primary forest, which further lessens its vulnerability.

**Bibliography.** Aleixo (1999), Cory & Hellmayr (1924), Isler & Whitney (2002), Machado (1999), Naka *et al.* (2000), Parker (2003a), Parker & Goerck (1997), de la Peña (1988), Ridgely & Tudor (1994), do Rosário (1996), Schönewetter & Meise (1967), Scott & Brooke (1985), Sick (1993, 1997), Teixeira & Gonzaga (1983a), Teixeira *et al.* (1989), Whitney (2003b), Zimmer (2003a).

## 132. Orange-bellied Antwren

### *Terenura sicki*

**French:** Grisin de Sick **German:** Schwarzrücken-Ameisenfänger **Spanish:** Tiluchi de Sick  
**Other common names:** Alagoas Antwren

**Taxonomy.** *Terenura sicki* Teixeira and Gonzaga, 1983, Serra Branca, Murici, Alagoas, Brazil. Forms a superspecies with *T. maculata*; further analysis of molecular, vocal and other characteristics that may differentiate them is needed. Monotypic.

**Distribution.** NE Brazil in E Pernambuco and E Alagoas.

**Descriptive notes.** 9.5-10.5 cm; 6.5-7 g. Male has forehead to upper mantle black, streaked white; rest of upperparts black with few white streaks, hidden white patch under scapulars; wings black, flight-feathers edged pale, coverts broadly tipped white; tail blackish; throat and underparts white. Female differs from male in rufous back and rump, white parts of head tinged pale buff, orange underparts. Voice: Loudsong a long dry rattle, calls a sharp "chip" and slightly longer, lower downslurred note; both similar to those of *T. maculata*.

**Habitat.** Canopy and subcanopy of semi-humid upland evergreen forest, at 200-550 m.

**Food and Feeding.** Little published. Feeds on variety of small insects, probably also spiders; stomach contents of holotype included beetles (Coleoptera) and cockroaches (Blattaria). Closely associated pair-members, individuals, or family groups forage mostly 7-20 m above ground, occasionally down to 5 m; alone or, more often, with mixed-species flocks of other insectivores. Very active and restless, progresses by short hops, seldom pauses for more than 1 second to scan; forages mostly in vines and creepers hanging along major trunks, as well as in crowns and terminal twiggy branches of mid-storey and emergent trees; when moving to another tree, often flies directly into a woody vine tangle at mid-height up trunk, hitches its way up slender hanging vines for several metres, then finally drifts towards crown or peripheral branches, before changing to yet another tree. Perch-gleans prey from tops and bottoms of live leaves (often large ones), leaf petioles, stem and vine surfaces, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; regularly hangs head first or upside-down to glean prey from tops of lower leaves; also makes short (less than 30 cm) hover-gleans to underside of overhanging vegetation; frequently flutters abruptly down for several metres in pursuit of flushed prey. Occasionally scans dead leaves and probes lightly into the curl with its bill, but more often passes these by without inspection. Not known to follow army ants.

**Breeding.** Nest-building observed in Nov; on basis of gonadal and moult condition of specimens, season thought to start in Nov and continue into Feb. Nest found in final stages of construction, a small cup 8.2 cm long, 5.6 cm wide, 4.9 cm deep, similar in general shape to nests of *Thamnophilus* and *Dysithamnus*, contained moss and some filaments of *Marasmius* fungi, suspended c. 10-12 m above ground from fork of nearly horizontal branch among dense foliage of mid-storey tree. Juveniles join adults in mixed-species flocks in Feb.

**Movements.** Resident.

**Status and Conservation.** **ENDANGERED.** Restricted-range species: present in Atlantic Slope of Alagoas and Pernambuco EBA. Locally uncommon to fairly common. Known from only a handful of forest fragments in foothills of Alagoas and Pernambuco; total range estimated at a mere 120 km<sup>2</sup>. Global population thought to number 1000-2500 individuals, and assumed to be declining as result of ongoing habitat destruction. Considered fairly common at Murici, uncommon at Usina Serra Grande, and regularly recorded at Pedra Talhada, with additional records from Novo Lino (1986) and Água Azul (1989); two of these areas, the Murici Ecological Reserve (also known as Pedra Branca, Serra Branca and, in part, Fazenda Bananeira; combined fragments estimated in 1995 to cover c. 3000 ha) and Pedra Talhada State Park (4469 ha), are in theory protected. Protection at latter is enforced by guards, and significant areas within the reserve are being reforested with native trees; reserve at Murici, however, is privately owned, and was still being selectively logged in Jan 2000, with several new jeep paths cut through the forest to remove timber. Selective logging a major threat, since this species has been shown not to persist in degraded second-growth woodland. Clear-cutting and burn-

ing of second-growth forest is also continuing around edges of Murici Reserve, and has successively reduced extent of forest each year since 1996. True protection of this key area (the type locality) is critical for the long-term survival of this species, as well as that of other threatened endemics such as *Myrmotherula snowi* and the Alagoas Foliage-gleaner (*Philydor novaesi*), both of which are known only from the Murici Reserve. Most of Alagoas has already been deforested (estimated 2% of original forest remains), primarily for sugar-cane production. This antwren has not been found in remaining patches of lowland forest near coast; as several other special birds of the region, it appears to be part of a unique upland avifauna. In addition to enforced protection of existing reserves, surveys to locate additional patches of ridgetop forest with populations of this and other regional endemics need to be undertaken as a matter of priority. Usina Serra Grande is another potential key reservoir for this species; as such, its protection should also be ensured.

**Bibliography.** Anon. (2000a, 2001b, 2002a), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Isler & Whitney (2002), Ridgely & Tudor (1994), Sick (1993, 1997), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Teixeira (1987b), Teixeira & Gonzaga (1983a), Teixeira, Nacinovic & Luigi (1988), Teixeira, Otoch *et al.* (1993), Wege & Long (1995), Willis & Weinberg (1990), Zimmer (2003a).

## 133. Rufous-rumped Antwren

### *Terenura callinota*

**French:** Grisin à croupion roux **German:** Rostbüzel-Ameisenfänger **Spanish:** Tiluchi Lomirrufo  
**Other common names:** Perija Antwren (Venezuelana)

**Taxonomy.** *Formicivora callinota* P. L. Selater, 1855, "Bogotá" = probably nearby Cundinamarca, Colombia.

Closely related to *T. humeralis* and *T. sharpei*. Includes "*Hylophilus puella*", original description of which was based on a female of present species. Races exhibit minimal differences in plumage, but appear to be isolated geographically from one another; *venezuelana* has sometimes been treated as a separate species. Recent records in Mérida and Barinas (W Venezuela) presumed to relate to latter race; further study required. Four subspecies recognized.

**Subspecies and Distribution.**

*T. c. callinota* (P. L. Selater, 1855) - Costa Rica (Caribbean slope S from S Alajuela), Panama (Chiriquí, Bocas del Toro, Veraguas, E Darién), Colombia (locally from Valle del Cauca and Cundinamarca S to Nariño and W Caquetá), Ecuador (both slopes, on Pacific S to El Oro) and N Peru (Piura, Cajamarca, Amazonas).

*T. c. venezuelana* Phelps, Sr. & Phelps, Jr., 1954 - NW Venezuela in Sierra de Perijá; also, recent sight records in Mérida and Barinas.

*T. c. guianensis* Blake, 1949 - S Guyana and C Surinam.

*T. c. peruviana* Meyer de Schauensee, 1945 - C Peru (S of R Marañón, from San Martín S to Junín, also S Cuzco).

**Descriptive notes.** 9.5-10.5 cm; 7-8 g. Male has black crown and nape, whitish supercilium, thin dark line through eye; back olive, rump cinnamon-rufous, uppertail-coverts olive-yellow, tail greyish olive-brown; wings blackish-grey, tinged olive, flight-feathers edged pale olive-yellow, greater and median coverts tipped pale yellow, bend of wing and hidden patch under scapulars yellow; side of head, throat and anterior underparts pale grey, lower underparts yellow. Female resembles male, but crown, nape and eyeline olive-brown, supercilium pale grey, no hidden patch under scapulars, wings dark olive-brown. Race *peruviana* has yellow below extending up into

lower breast; *guianensis* has rump rufous-chestnut, hidden patch under scapulars reduced or absent; *venezuelana* female has back olive-grey, throat and underparts whiter. Voice: Loudsong in Colombia a series (e.g. 26 notes, 2-6 seconds) of initially distinct, countable notes that rise in pitch and shorten in length to become high-pitched trill; in Central America loudsong slower, notes more countable. Call high-pitched and abrupt, sometimes in short series in which final notes descend in pitch.

**Habitat.** Canopy and subcanopy (often lower at forest edge) of montane evergreen forest, at 600-2400 m; 750-1200 m in Costa Rica and Panama. In Costa Rica confined to the wettest, most moss-laden forests.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae, orthopterans, beetles (Coleoptera); also on spiders. Closely associated pair-members, individuals, or family groups forage mostly from 15 m above ground to the canopy, regularly descending to 6 m at forest edge; almost invariably in company of mixed-species flocks of other insectivores. Very active, restless forager, progresses by short hops, seldom pauses for more than 1 second to scan; in almost constant motion, nervously flicks both wings. Usually forages in terminal leafy branchlets in crowns and outer branches of trees, to lesser extent also in hanging clusters of leafy vines near trunks. Perch-gleans prey from tops and bottoms of live leaves, leaf petioles, twigs, vines and moss, by reaching up, out or down with quick stabs of the bill; frequently hangs acrobatically head first or upside-down from margins of leaves in manner of greenlets (*Hylophilus*) to glean prey from top surfaces of lower leaves. Not known to follow army ants.

**Breeding.** Almost nothing known. Season in Costa Rica probably Mar-May (as for most insectivores), as indicated by Mar record of female carrying nest material (moss).

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Seemingly uncommon throughout most of its extensive range; in many regions known only from a handful of specimens and sight records, although this tiny, canyon-dwelling bird is easily overlooked. Occurs in La Planada Nature Reserve and Rio Nambi Natural Reserve, in Colombia. Foothill and middle-elevation slopes favoured by this species are often subject to the most intensive pressure from human colonization and cultivation, which could place some populations at risk.

**Bibliography.** Cory & Hellmayr (1924), Fjeldsa & Krabbe (1990), Haverschmidt & Mees (1994), Hilty (1997, 1999, 2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Parker & Carr (1992), Ridgely & Gaulin (1980), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Robbins & Ridgely (1990), Robbins *et al.* (1985), Schulenberg & Awbrey (1997a), Stiles (1983a), Stiles & Skutch (1989), Stotz *et al.* (1996), Wetmore (1972), Willis (1988b), Zimmer, J.T. (1932f), Zimmer, K.J. (2003a).

## 134. Chestnut-shouldered Antwren

*Terenura humeralis*

French: Grisin à épaules rousses

Spanish: Tiluchi Hombrocastaño

German: Rotschulter-Ameisenfänger

**Taxonomy.** *Terenura humeralis* P. L. Selater and Salvin, 1880, Sarayacu, Ecuador. Closely related to *T. callinota* and *T. sharpei*. Described race *transfluvialis* based on pair of individuals from single location in W Brazil (Hyutanahan, on R Purus), but more thorough study of geographical variation required before any races regarded as tenable. Monotypic.

**Distribution.** E Ecuador (primarily S of R Napo), E Peru (S of R Napo), SW Amazonian Brazil (S Amazonas E to upper drainages of R Juruá, R Purus and R Madeira and N Rondônia) and NW Bolivia (Pando, La Paz).

**Descriptive notes.** 9.5-10.5 cm; 7-8 g. Male has black crown and nape, whitish supercilium, thin dark line through eye; back greenish-olive, rump rufous-chestnut, tail greyish-olive; wings blackish-grey, tinged olive, flight-feathers edged pale olive-yellow, greater and median coverts tipped whitish, bend of wing and hidden patch under scapulars rufous-chestnut; side of head, throat and anterior underparts pale grey, lower breast to vent pale yellow. Female resembles male, but crown, nape and eyeline olive-brown, supercilium pale grey, no hidden patch under scapulars, wings dark olive-brown, often a trace of chestnut on lesser wing-coverts.

**Voice.** Loudsong a series of initially countable notes rising in pitch and shortening in length to become high-pitched trill, like that of *T. callinota* but possibly slower (e.g. 26 notes, 2.9 seconds).

**Habitat.** Canopy and subcanopy of lowland evergreen forest, to 650 m. Found in both *terra firme* and seasonal forests.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders; observed to take small moths (Lepidoptera), a caterpillar c. 12 mm long, and minute prey too small to be identified. Closely associated pair-members, individuals, or family groups forage mostly from 15 m above ground to the canopy, occasionally down to 8 m or lower at forest edges; almost invariably in company of mixed-species flocks of other insectivores. Moves restlessly and hyperactively through canopy and subcanopy; progresses by short hops, seldom pauses for more than 1 second to scan; forages mostly on terminal branchlets and foliage. Perch-gleans prey from tops and bottoms of live leaves, leaf petioles, vines and twigs, by reaching up, out or down with quick stabs of the bill; often hangs acrobatically; head first or upside-down from leaf margins in manner of greenlets (*Hylophilus*) to glean prey from top surfaces of lower leaves; pursues escaping prey in fluttering and direct flight, and observed capturing prey in air. Occasionally probes dead leaves. Not known to follow army ants.

**Breeding.** Little known. An individual observed as it gathered long strands of moss in Aug in SE Peru (Madre de Dios).

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout most parts of its range. This includes some large protected areas, e.g. Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Serra do Divisor National Park, in Brazil, and Madidi National Park, in Bolivia; also vast contiguous areas of intact, suitable habitat which, although not formally protected, appear to be in little danger of development in near future. Recent fieldwork has shown species' range to be much more extensive than previously thought, reaching S to Bolivia (at Camino Mucden, in Pando, and at Alto Madidi, in La Paz) and E to Rondônia, in Brazil.

**Bibliography.** Alvarez (1994), Alverson, Moskovits & Shopland (2000), Alverson, Rodríguez & Moskovits (2001), Cory & Hellmayr (1924), Foster *et al.* (1994), Hackett & Rosenberg (1990), Isler & Whitney (2002), Munn (1984, 1985), Parker (1982, 2003a, 2003b), Parker & Bailey (1991), Parker & Remsen (1987), Parker *et al.* (1991), Remsen (1986), Remsen & Parker (1984), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg (2003), Servat (1996), Sick (1993), Stotz (1990b), Stotz *et al.* (1997), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Zimmer, J.J. (1932), Zimmer, K.J. (2003a).

## 135. Yellow-rumped Antwren

*Terenura sharpei*

French: Grisin à croupion jaune

Spanish: Tiluchi Lomigualdo

German: Gelbbürzel-Ameisenfänger

**Taxonomy.** *Terenura sharpei* Berlepsch, 1901, Quebrada Honda, Cochabamba, Bolivia.

Closely related to *T. callinota* and *T. humeralis*. Monotypic.

**Distribution.** E slope of Andes in extreme S Peru (Cuzco, Puno) and W Bolivia (La Paz, Cochabamba).

**Descriptive notes.** 9.5-10.5 cm; 7-8 g. Male has black crown and nape, whitish supercilium, thin dark line through eye; back olive, lower back and rump yellow, tail greyish-olive; wings blackish-grey, tinged olive, flight-feathers edged pale olive-yellow, greater and median coverts tipped whitish, bend of wing and hidden patch under scapulars yellow; side of head, throat and anterior underparts pale grey, lower underparts yellow. Female resembles male, but crown, nape and eyeline olive-brown, supercilium pale grey, no hidden patch under scapulars, lower back and rump yellowish-olive, wings dark olive-brown. **Voice.** Loudsong

a series of initially countable notes rising in pitch and shortening in length to become high-pitched trill, like that of *T. callinota* but may be faster and longer (e.g. 49 notes, 3-6 seconds) and with trill more clearly descending in pitch.

**Habitat.** Canopy and subcanopy of montane evergreen forest, at 750-1700 m.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated partners, individuals, or family groups forage mostly 10-20 m above ground, almost invariably in company of mixed-species flocks; most common flock associates Streaked Xenops (*Xenops rutilans*), Marble-faced Bristle-tyrant (*Pogonotriccus ophthalmicus*), Buff-banded Tyrannulet (*Mecocerculus*

*hellmayri*) and Slate-throated Redstart (*Myioborus miniatus*). Most foraging is in areas of very dense foliage, and almost always within 1 m of outer edge of canopy. Moves very rapidly through foliage, perch-gleaning prey from both surfaces (more commonly from upper surface) of green leaves with frequent lunging and darting movements; also hangs down from twigs to reach upper surface of leaves below. Not known to follow army ants.

**Breeding.** Almost nothing known. Season at Serranía Bellavista (La Paz) thought to be at least Jun-Jul; male with enlarged testes in late Jun; female-plumaged bird on 25th Jun may have been recently fledged juvenile; frequent song noted in Jun and early Jul.

**Movements.** Presumed resident.

**Status and Conservation.** ENDANGERED. Restricted-range species; present in Bolivian and Peruvian Lower Yungas EBA. Has very small range, but within region where there are several large, recently established protected areas containing appropriate habitat. Notable among these are Manu National Park and Biosphere Reserve (numerous recent documented reports) and Tambopata-Candamo Reserved Zone (current boundaries encompass locality of a specimen from late 19th century), in Peru, and Madidi National Park and Integrated Management Area, Ambo National Park, Bellavista Protection Forest Reserve and Carrasco National Park, in Bolivia. Predicted that more extensive surveys will locate additional populations of this threatened species within these protected areas. Widespread habitat loss in upper tropical zone along Amazonian slope of Andes poses major threat to a number of birds restricted to this elevational zone. Much of the large-scale clearance of forest for, especially, coffee, citrus, tea and coca, occurs slightly below this species' elevational range, but clearance for subsistence agriculture by recent colonists from Altiplano extends threat to higher levels.

**Bibliography.** Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Cory & Hellmayr (1924), Isler & Whitney (2002), Remsen *et al.* (1982), Ridgely & Tudor (1994), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stotz (2003), Stotz *et al.* (1996), Wege & Long (1995), Zimmer (1932).

## 136. Ash-winged Antwren

*Terenura spodioptila*

French: Grisin spodioptila

German: Rotrücken-Ameisenfänger

Spanish: Tiluchi Piojito

**Taxonomy.** *Terenura spodioptila* P. L. Selater and Salvin, 1881, Bartica Grove, Guyana.

Relationships with others of genus unclear. Race *meridionalis* poorly known. Sight records from Colombia, NE Ecuador and NE Peru tentatively assigned to this species (race *signata*), but further study needed. Birds from French Guiana and adjacent NE Brazil described as race *elaepteryx*, but considered indistinguishable from nominate. Three subspecies recognized.

**Subspecies and Distribution.**

*T. s. signata* J. T. Zimmer, 1932 - SE Colombia (Cauquetá, Guainia), extreme NE Ecuador (Sucumbios N of R Aguatico), NE Peru (Loreto N of R Napo) and NW Amazonian Brazil (upper R Negro region). *T. s. spodioptila* P. L. Selater & Salvin, 1881 - S Venezuela (Amazonas, Bolívar), the Guianas and NE Amazonian Brazil (Roraima, lower R Negro region, N Pará, W Amapá).

*T. s. meridionalis* Sneath, 1925 - SC Amazonian Brazil between lower R Madeira and lower R Tapajós.

**Descriptive notes.** 9.5-10.5 cm; 6.5-7.5 g. Male nominate race has black crown and nape, whitish supercilium, thin dark line through eye; upper mantle grey, remainder of upperparts rufous-chestnut, tail grey-brown; wings black, remiges edged pale grey, greater and median coverts tipped white; entire underparts pale grey, whitest on throat and belly. Female differs from male in having crown and upper mantle yellowish-brown, supercilium, throat, breast and flanks tinged buffy-brown. Subadult both sexes has remiges edged olive-green, underwing-coverts tinged yellowish. Race *signata* male differs from nominate in chest-

nut lesser wing-coverts; *meridionalis* has wing edgings olive, wing-covert tips and belly tinged greenish-yellow. **Voice.** Loudsong of nominate race and of *signata* (in upper R Negro) a long introductory note quickly accelerating into very rapid trill that descends in pitch, ending with 2-3 distinct, countable abrupt notes; loudsongs of *meridionalis* and N Peruvian *signata* lack countable terminal notes, more like that described for *T. callinota*. Call short and abrupt, sometimes in short series in which notes change pitch.

**Habitat.** Canopy and subcanopy of lowland evergreen forest; mostly below 600 m, to 1100 m in Venezuelan tepuis. Primarily in *terra firme* forest.

**Food and Feeding.** Little published. Feeds on variety of insects and spiders; recorded food in Surinam includes ants (Formicidae), hemipterans, homopterans (Jassidae), spiders. Closely associated pair-members, individuals, or family groups forage mostly from 10 m above ground to the canopy, occasionally lower at forest edges, and almost invariably in company of mixed-species flocks of other insectivores. Very active, restless, progressing by short hops, seldom pausing for more than 1 second to scan; in almost constant motion, nervously flicks both wings or opens wings and fans tail. Usually forages in terminal leafy branchlets in crowns and peripheries of trees. Perch-gleans prey from tops and bottoms of live leaves, leaf petioles, twigs and vines, by reaching up, out or down with quick stabs of the bill; frequently hangs acrobatically head first or upside-down from margins of leaves in manner of greenlets (*Hylophilus*) to glean prey from top surfaces of lower leaves; from hanging position, regularly flutters abruptly several metres down to another perch; occasionally sallies to leaf surfaces and probes dead-leaf clusters. Not known to follow army ants.

**Breeding.** Almost nothing known. In Brazil, fledgling begging and flitting in understorey with food-carrying female nearby in Dec (Manaus), and pair collecting strands of moss and pieces of bark in Nov (R Tapajós).

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Fairly common throughout its range; easily overlooked. Range encompasses a number of large protected areas, e.g. Canaima, Duida, La Neblina and Yapacana National Parks and Alto Orinoco-Casiquiare Biosphere Reserve, in Venezuela, Brownsberg Nature Park and Raleigh Falls-Voltzberg National Park, in Surinam, and Jaú and Tapajós National Parks and BDFPP INPA forests N of Manaus, in Brazil; also contiguous expanses of intact suitable habitat that are not formally protected, but seem to be at little risk of being developed in near future.

**Bibliography.** Cohn-Haft *et al.* (1997), Cory & Hellmayr (1924), Friedmann (1948), Haverschmidt & Mees (1994), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Oniki & Willis (1982), Oren & Parker (1997), Parker (2003a, 2003b), Ridgely & Tudor (1994), Sick (1993), Stotz (1990b), Stotz & Bierregaard (1989), Stotz *et al.* (1996), Thiollay (1994), Tostain *et al.* (1992), Willis (1977), Zimmer, J.T. (1932), Zimmer, K.J. (2003a).

## 137. Blackish Antbird

### *Cercomacra nigrescens*

**French:** Grisin noirâtre **German:** Schwarzgrauer Ameisenfänger **Spanish:** Hormiguero Negruzco

**Taxonomy.** *Perenostola nigrescens* Cabanis and Heine, 1859, Cayenne, French Guiana. Considered to form a species group with *C. laeta*, *C. tyrannina*, *C. parkeri* and *C. serva* on basis of plumage and vocal characters, and pending completion of major genetic study. Substantial vocal and distinct plumage differences among some populations of present species suggest that more than one species is probably involved. Racial identity of birds in N Brazil (N bank of R Amazon in E Amazonas and Pará) uncertain; tentatively placed in nominate, but may belong with *approximans* or *fusca*. Races *aequatorialis* and *notata* appear to intergrade. Six subspecies recognized.

#### Subspecies and Distribution.

- C. n. nigrescens* (Cabanis & Heine, 1859) - Surinam (coastal region) and French Guiana; also N bank of R Amazon in Brazil (E Amazonas, Pará).
- C. n. aequatorialis* J. T. Zimmer, 1931 - E Andean slopes from S Colombia (Nariño) S to NE Peru (Amazonas, San Martín).
- C. n. notata* J. T. Zimmer, 1931 - E slopes in EC Peru (W Ucayali S to Junín).
- C. n. fusca* J. T. Zimmer, 1931 - lowlands in E Ecuador, E Peru, extreme SE Colombia (S Amazonas), SW Amazonian Brazil (SW Amazonas, Acre) and NE Bolivia (Pando, La Paz, W Beni, Cochabamba).
- C. n. approximans* Pelzeln, 1868 - SC Amazonian Brazil (from SE Amazonas E to R Tapajós, S to Rondônia and Mato Grosso W of R Teles Pires) and E Bolivia (E Beni, N Santa Cruz).
- C. n. ochrogyna* Sneath, 1928 - EC Amazonian Brazil (Pará E of R Tapajós and W of R Tocantins, Mato Grosso NE of R Teles Pires).

**Descriptive notes.** 14-15 cm; 17-24 g (appears to vary among races, females may weigh less). Male nominate race is blackish-grey; interscapular patch and hidden patch under scapulars white; wing-coverts narrowly edged white at tips. Female has crown and upperparts olive-brown, tinged rufous, interscapular patch white, tail blackish, forehead, face and underparts orange-rufous, tinged olive on flanks. Race *notata* male is paler than nominate, female upperparts more olivaceous, tail light brownish; *aequatorialis* is similar to previous, but male has broader wing-covert tips, female upperparts more rufescent; *fusca* male is

slightly paler than nominate, female crown more tawny and head side less rufescent (creating less contrast), back slightly paler and browner, interscapular patch smaller, *approximans* male is paler than previous, wing-covert tips broader, female browner, covert tips cinnamon; *ochrogyna* resembles previous, but female paler and more ochraceous. **VOICE.** Male loudsong nominate race a single low "wup" followed by short rattle of variable length (e.g. total 6 notes, 0.7 seconds) that usually becomes less intense; males of other races differ in change of pitch of rattle (descends in most regions, but also flat or may rise and fall slightly), in pace, and in change of pace, *fusca* most distinct with rattle condensed into long note dropping in pitch and intensity and sounding like "what cheer"; female loudsong similar in all races, a series of countable "wup" notes (e.g. 5 notes, 1.5 seconds) rising up the scale, notes accelerate slightly or lengthen slightly in some races, often given in duet after start of male loudsong. Call a harsh, unmusical "chirr", variable in length, usually flat but sometimes downslurred.

**Habitat.** Understorey of humid evergreen-forest edge (*terra firme*, transitional, *várzea*), densely vegetated forest light-gaps, and adjacent second-growth woodland, bamboo thickets, vine tangles, revegetating clearings and overgrown plantations; lowlands mostly below 600 m; mostly above 800 m, to 2200 m, in Andes. Lowland populations appear to vary geographically in habitat preferences, but generally in dense vine thickets along streams and forest openings; in some regions concentrated in swampy patches of floodplain *Heliconia*, in others favours bamboo thickets often, but not necessarily, near water. Andean populations in shrubby forest borders and second-growth woodland.

**Food and Feeding.** Little published. Feeds on insects, probably also spiders. Closely associated pair-members, individuals, or family groups forage mostly 0-5 m above ground, occasionally higher; usually alone, but occasionally briefly joining mixed-species flocks of other insectivores as these pass through its territory. Forages mostly within cover of shaded vine-covered shrubs and small trees, bamboo thickets, or dense *Heliconia* thickets, where difficult to observe. Active but methodical forager, progressing by short hops, separated by pauses of a few seconds to scan for prey; clings laterally to slender vertical stems and vines; posture varies from nearly horizontal to three-quarters upright, with tail usually held level with body or slightly cocked, and sometimes swung from side to side, wings regularly flicked; movements somewhat erratic, often follows zigzag course with frequent changes of direction. Most prey perch-gleaned from tops and bottoms of live leaves, from stems, vines and branch surfaces, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; often makes short jump-gleans, or slightly longer (to 30 cm) fluttering sallies, to underside of overhanging vegetation. Rare observations (Brazil and Ecuador) of following swarms of army ants (*Eciton burchelli*) as these pass through dense second-growth thickets.

**Breeding.** Nothing known; egg description reported from Surinam, but needs confirmation.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Generally fairly common throughout most of its extensive range, which includes a number of large parks and reserves. Conservation status may be altered by outcome of pending taxonomic analyses, which could split this species, as presently constituted, into two or more biological species, thereby fragmenting current extensive range into smaller components, each with its own conservation challenges. None of the currently recognized races, however, appears to be particularly rare or at any immediate risk. Preference of all races for second-growth and edge habitats renders them less vulnerable to disturbance than are most antbirds.

**Bibliography.** Álvarez (1994), Alverson, Moskovits & Shopland (2000), Alverson, Rodríguez & Moskovits (2001), Bierregaard *et al.* (1997), Bond (1950), Cory & Hellmayr (1924), Cox *et al.* (1992), Fitzpatrick & Willard (1990), Foster *et al.* (1994), Haverschmidt & Mees (1994), Hilty & Brown (1986), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Killeen & Schulenberg (1998), Kratter (1997a), O'Neill & Pearson (1974), Oren & Parker (1997), Parker (2003a), Parker & Remsen (1987), Remsen & Parker (1983), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Robinson & Terborgh (1997), Rosenberg, G.H. (1931a), Zimmer, K.J. (2003a).

## 138. Willis's Antbird

### *Cercomacra laeta*

**French:** Grisin de Willis **German:** Amazonasameisenfänger **Spanish:** Hormiguero de Willis

**Taxonomy.** *Cercomacra tyrannina laeta* Todd, 1920, Benevides, Pará, Brazil. Probably closest to *C. tyrannina* and until recently treated as conspecific. Together with *C. nigrescens*, *C. parkeri* and *C. serva* they are considered to form a species group, on basis of plumage and vocal characters, and pending completion of major genetic study. Three subspecies recognized.

#### Subspecies and Distribution.

- C. l. waimiri* Bierregaard *et al.*, 1997 - NC Amazonian Brazil (E Roraima, NE Amazonas, NW Pará) and extreme S Guyana.
- C. l. laeta* Todd, 1920 - SE Amazonian Brazil (E Pará, W Maranhão).
- C. l. sabinoi* Pinto, 1939 - coastal NE Brazil in Pernambuco and Alagoas.

**Descriptive notes.** 13.5-14.5 cm; 15-17 g. Male nominate race is blackish-grey, somewhat greyer below; interscapular patch white, wing-coverts and outer rectrices narrowly tipped white. Female is olive-grey above and on ear-coverts, wings and tail browner, wing-coverts edged cinnamon, interscapular patch vestigial, throat and underparts tawny-buff, flanks tinged olive. Race *waimiri* male is darker and purer grey than nominate, lacks pale tips on rectrices, female has orange-cinnamon ear-coverts, dark grey wing-coverts with prominent cinnamon-brown edges; *sabinoi* female has underparts variably pale cinnamon. **VOICE.** Male loudsong

an introductory note followed by 4-6 doublets with second note lower-pitched; female a short series of usually 4 notes, notes initially longer than those of male but becoming shorter and rising in pitch, usually given in duet after start of male loudsong.

**Habitat.** Understorey of lowland evergreen-forest edge and taller second-growth woodland, usually near water, to 300 m; to 600 m in E Brazil (*sabinoi*). Nominant race typically inhabits shrubby edges of *várzea* forest or forest bordering small streams; *sabinoi* in tall second-growth borders of lowland and foothill forest, also densely vegetated light-gaps (often with *Heliconia* thickets) within forest, not necessarily near water. In W of range (*waimiri*) is partly sympatric with *C. tyrannina*; seems, at least in region of overlap, to be more associated with white-sand *campina* woodland, occupying shrubby borders of woodland, particularly near streams or in swampy, poorly drained areas.

**Food and Feeding.** Little published. Feeds on variety of insects, including orthopterans and lepidopterans; also on spiders. Closely associated partners, individuals, or family groups forage mostly 0-3 m above ground, usually not associated with mixed-species flocks. Active but methodical forager, progressing by short hops, separated by pauses of a few seconds to scan for prey; posture varies from nearly horizontal to three-quarters upright, with tail usually held level with body or slightly cocked; shallowly flicks both wings as it forages. Forages mostly in dense tangles and thickets; perch-gleans most prey from tops and bottoms of live leaves and from stems, vines and branches, by reaching up, out or down, or by short horizontal lunges; sometimes makes short (less than 30 cm) fluttering sallies to glean items from beneath overhanging vegetation. Occasionally follows army ants (*Eciton burchelli*) as these pass through dense second-growth thickets; rarely follows ants for long periods.

**Breeding.** Little known. Nests found in Feb-Mar in Pará (near Belém). Nest bag-shaped, made of tightly woven and twisted black fibres, with small entrance, placed c. 25-40 cm above ground deep in thicket in second growth, sometimes along streambank. Clutch 2 eggs, white with dark spots and streaks; female incubated at one nest, but incubation probably by both sexes (as in other members of family).

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Nominant race at least locally fairly common; *waimiri* uncommon, and seemingly patchily distributed throughout its broader range; *sabinoi* poorly known, seems to be rare and localized. The ability of all races to exploit second-growth and edge habitats probably renders this species less vulnerable to disturbance than are most antbirds. Patchy nature of its distribution and generally low level of abundance throughout most of its range do, however, suggest that some monitoring is called for. More surveys needed in order better to assess population levels, distributional limits and habitat requirements of all three subspecies.

**Bibliography.** Bierregaard *et al.* (1997), Braun *et al.* (2000), Cory & Hellmayr (1924), Isler & Whitney (2002), Novaes (1969, 1970, 1973), Novaes & Lima (1992), Sick (1993), Sneath (1935), Whittaker (2003a), Willis (1985a), Zimmer (2003a).

## 139. Dusky Antbird

### *Cercomacra tyrannina*

**French:** Grisin sombre **German:** Dunkelgrauer Ameisenfänger **Spanish:** Hormiguero Tirano  
**Other common names:** Tyrannine Antbird

**Taxonomy.** *Pyriglena tyrannina* P. L. Sclater, 1855, "Bogotá" = probably nearby Cundinamarca, Colombia.

Probably closest to *C. laeta*, which formerly treated as conspecific; until recently also included *C. parkeri* as a highland population in Colombia. These three along with *C. nigrescens* and *C.*

*serva* are considered to form a species group, on basis of plumage and vocal characters, and pending completion of major genetic study. At least some of the plumage differences from which races were described appear to be due to clinal variation; analysis of other parameters, including vocalizations, required in order to define geographical populations more accurately, and ranges listed are therefore provisional. Described race *rufiventris* (E Panama S to W Ecuador) considered synonymous with nominate on basis of recent study of plumage variation. Four subspecies recognized.

#### Subspecies and Distribution.

*C. t. crepera* Bangs, 1901 - SE Mexico (SE Veracruz, NE Oaxaca and N Chiapas E to S Quintana Roo), Belize, and Guatemala and Honduras (Caribbean slope) S to W Panama (W & C Chiriquí, Bocas del Toro, NW Veraguas).

*C. t. tyrannina* (P. L. Selater, 1855) - C & E Panama (E from E Chiriquí, W Colón and NE Coclé), Colombia (Pacific slope, lower Cauca and Magdalena Valleys, and E of Andes S to R Caquetá), W Ecuador (S to S Guayas, one record in El Oro), S Venezuela (Bolívar, Amazonas) and extreme NW Brazil (N Amazonas W of lower R Negro, S to R Japurá).

*C. t. vicina* Todd, 1927 - NW Venezuela (S Zulia S to Táchira and E to Barinas, NW Apure and W Bolívar) and E slope of Andes in N Colombia (Casanare).

*C. t. saturator* Chubb, 1918 - the Guianas and NE Amazonian Brazil (Roraima and from E of lower R Negro E to Amapá).

**Descriptive notes.** 13.5-14.5 cm; 15-19 g. Male nominate race is slate-coloured above, wings and tail somewhat darker, interscapular patch white, wing-coverts and outer rectrices narrowly tipped white; slightly paler below, palest on chin, tinged clay colour posteriorly; iris rich chocolate-brown. Female has crown, upperparts and wings dark olive-grey, tinged tawny, interscapular patch vestigial, wing-coverts edged cinnamon, tail dark greyish-brown, supercilium, throat and underparts tawny-buff, flanks tinged olive. Juvenile resembles female until 1 year old; iris grey to grey-brown in first year, brown in second year, becoming chocolate-brown in third year. Race *crepera* male is blacker, pale tips of wing-coverts and tail reduced in width, female wings more rufescent; *vicina* male is more clearly brownish-olive on wings, tail and flanks; *saturator* male is blacker, crissum feathers tipped white, usually some white tips on centre of breast, female greyer above. **VOICE.** Male loudsong typically a series of relatively short notes at even pitch and pace except for lower-pitched initial and terminal notes, geographically variable in number of notes, length of individual notes, pace and constancy of pitch (e.g. 8 notes in 1 second in Mexico, 22 notes in 2 seconds in Guyana); female loudsong a series of long notes rising in pitch followed by series of abrupt notes typically remaining at same pitch, varies in number of long notes and of short notes, length of individual notes and constancy of pitch (e.g. 9 notes in 1-7 seconds in Mexico, 14 notes in 3-1 seconds in Surinam); unmated individuals of each sex deliver a "courtship song" that includes elements of the other gender's loudsong. Calls may also vary geographically, include 1-6 soft abrupt "chip" notes that usually shift in pitch in multiple-note calls, and short rattle or "chirr".

**Habitat.** Thick understory of lowland and foothill evergreen forest at edges of clearings, stream edges, shrubby forest borders, also secondary forest with dense bushes and vines. Mostly below 1200 m, locally to 1900 m; in Central America mostly below 750 m, occasionally to 1200 m, rarely higher in Panama; in Colombia to 750 m (records at 1130-1830 m appear all to refer to *C. parkeri*); in Ecuador mainly below 800 m, locally to 1400 m. Seldom ventures far into interior of forest; also seldom present in second growth if not bordering taller woodland or forest.

**Food and Feeding.** Feeds on variety of insects, including beetles (Coleoptera), lepidopteran larvae, wasps (Hymenoptera), hemipterans, homopterans, orthopterans; also on spiders. Stomach contents from Panama included orthopterans, cockroaches (Blattellidae), caterpillars, beetles (including Cerambycidae), ants (Formicidae), spiders; from Surinam beetles, orthopterans, spiders. Closely associated partners, individuals, or family groups forage mostly 0-5 m above ground; rarely and only briefly joins mixed-species flocks as these move through its territory, although in Panama associates occasionally with *Myrmeciza longipes*, with which it often shares territory. Active but methodical forager, progressing by short hops, with frequent pauses of 1-3 seconds to scan for prey; posture varies from nearly horizontal to three-quarters upright, with tail usually held level with body, and often shallowly flicks both wings as it forages; clings laterally to slender vertical stems and vines, usually hitching upwards from side to side. Forages mostly in shaded thickets and vine tangles, sometimes on ground. Perch-gleans most prey from tops and bottoms of live leaves and from stems, vines and branch surfaces, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; also makes short (usually less than 30 cm) fluttering sallies and even shorter jump-gleans to take prey from underside of overhanging vegetation; seldom hangs or uses other acrobatic manoeuvres. Sometimes probes curled dead leaves, but just as frequently ignores them. In Panama, regularly attends swarms of army ants (*Eciton burchelli*, *Labidus praedator*) moving through dense second growth or scrub along roads, streams or hillside areas, rarely for extended period, but recorded as following ants for up to 185 minutes; takes low (1-3 m) perches on slender vertical stems, most prey captures over ants involving close perch-gleans from leaves, vines, stems and trunks; rarely short sallies to ground, debris, leaves or stems.

**Breeding.** Feb-Oct in Costa Rica and Panama and Aug-Nov in Amazonian Brazil; additional nest and egg descriptions from Nicaragua and Colombia, and additional egg descriptions from Mexico and Venezuela. Nest in Central America a deep pensile pouch with oblique opening near top, thick walls composed of dead leaves, plant fibres, dead blades of grass and strips of palm fronds, suspended by fungal strands and similar, 0.6-3 m above ground from fork of slender drooping tree branch, vine, tall climbing sedge or climbing fern; one in Nicaragua described as globular and pendent, with entrance near top on one side, nearly roofed over, of dry leaves and palm shreds woven together with long shredded stems of ferns (some of these from stems hanging down 46 cm below nest), lined with fine fern stems, placed 2-3 m above ground, the whole resembling a naturally suspended ball of moss; two nests in Brazil looked like bunches of dead leaves, also pouch-shaped, one side of rim lower than other, of dried leaves and web-like rachides and veins of decomposing leaves, tied together by thin black rhizomorphs, lined with large leaves, decaying pieces of palm leaves and few leaf veins and rootlets, suspended 68 cm and 171 cm above ground from tips of thin leguminous vines (*Machaerium*, *Derris*), rim secured to vines by many black rhizomorphs. Normal clutch 2 eggs, in Central America dull white or creamy with reddish-brown or vinaceous-brown (tending to violet) spots, spots all over or confined to or heaviest on larger end, in Brazil (Manaus) light pink, marked with thin faint dark lines and large lilac spots at larger end and towards middle (but not at smaller end); incubation by both parents during day, only by female at night, period 18-20 days in Panama, at least 14 days (exact period not known) in Brazil; both also brood and feed chicks, nestling period c. 11 days in Costa Rica, 9-11 days in Panama. In

an 8-year study in Panama, annual probability of success only 8%, primarily as a result of predation, but 25% in one year; annual survival rate, however, was 82%.

**Movements.** None recorded; presumed resident throughout range.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout its extensive range. Regions inhabited by this species encompass numerous protected parks and reserves. Its ability to occupy second-growth thickets and forest edge renders this species less vulnerable to disturbance than are most antbirds.

**Bibliography.** Allen (1998), Bierregaard *et al.* (1997), Blake & Loiselle (1991, 2001), Carriker (1910), Cody (2000), Cohn-Haft *et al.* (1997), Cory & Hellmayer (1924), Derrickson & Morton (1998), Dick *et al.* (1984), Eisenmann (1952), England (2000), Fitzpatrick & Willard (1990), Fleischer & Tarr (1995), Fleischer *et al.* (1997), Graves (1997), Haverschmidt & Mees (1994), Hilty (1997, 2003a), Hilty & Brown (1986), Howell, S.N.G. & Webb (1995a), Howell, T.R. ## 140. Parker's Antbird

### *Cercomacra parkeri*

**French:** Grisin de Graves **German:** Parkers Ameisenfänger **Spanish:** Hormiguero de Parker

**Taxonomy.** *Cercomacra parkeri* Graves, 1997, La Bodega, Antioquia, Colombia.

Appears closest to *C. tyrannina*, and until recently was treated as a highland population of latter. The two are considered to form a species group with *C. nigrescens*, *C. laeta* and *C. serva* on basis of plumage and vocal characters, and pending completion of major genetic study. Monotypic.

**Distribution.** Andes in WC Colombia (W slope of W range, N & E slopes of C range, probably also W slope of E range).

**Descriptive notes.** 13.5-14.5 cm. Male is slate-coloured above, wings and tail somewhat darker, interscapular patch white, wing-coverts and outer rectrices narrowly tipped white; slightly paler below, chin palest, flanks tending towards olivaceous tinge; iris rich chocolate-brown. Distinguished from extremely similar *C. tyrannina* by slightly longer tail on average, often more olivaceous flanks. Female has crown, upperparts and wings olive-grey, tinged tawny, side of head grey or brownish-grey, supercilium paler, interscapular patch absent or vestigial, wing-coverts edged cinnamon, tail dark grey-brown, throat and under-

parts tawny-buff, flanks tinged olive. **VOICE.** Male loudsong a muted note followed by higher-pitched, more intense series initially flat in pitch, then descending and accelerating as final notes shorten (e.g. 10 notes, 2-3 seconds); female similar in patterns of pitch and pace, but higher-pitched and shorter (e.g. 6 notes, 1-7 seconds), and notes downslurred, usually given in duet after start of male loudsong. Call a rapid sputter of notes.

**Habitat.** Borders and undergrowth of wet montane evergreen forest and tall second-growth woodland, at 1130-1950 m. Found in small (4-5 ha) forest fragments as well as large continuous forest. Most often in young, shrubby patches along borders; also in densely vegetated light-gaps within forest and bamboo (*Chusquea*) thickets.

**Food and Feeding.** Little known. Feeds on variety of insects and spiders; beetles (Coleoptera) most commonly found in stomach contents. Pair-members and family groups forage in undergrowth near ground level, sometimes ascending to mid-levels of adjacent trees; moves actively by hopping through branches, including vertical ones; glean prey from foliage. Typically forages apart from mixed-species flocks.

**Breeding.** Little known. Fledglings found in Apr and Jul in Antioquia.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Status uncertain. This recently described species has a limited geographical distribution and occupies a narrow elevational band, which suggests that total population size is small. This, combined with fact that mid-elevation Andean forests which it occupies are rapidly disappearing as a result of human colonization, logging, and cultivation for agriculture, suggests that it is at some degree of risk. This risk possibly ameliorated somewhat as the species is adapted to second growth and forest edge; such preferences, however, will not protect it from wholesale clear-cutting of forest. Additional surveys are needed in order to provide complete picture of its distributional limits, population densities, and basic ecological requirements.

## 141. Black Antbird

### *Cercomacra serva*

**French:** Grisin noir **German:** Südlicher Trauerameisenfänger **Spanish:** Hormiguero Negro

**Taxonomy.** *Pyriglena serva* P. L. Selater, 1858, Rio Napo, Ecuador.

Considered to form a species group with *C. nigrescens*, *C. laeta*, *C. tyrannina* and *C. parkeri* on basis of plumage and vocal characters, and pending completion of major genetic study. Birds from C Peru and W Brazil S to Bolivia described as race *hypomelaena*, but appear to represent S end of a cline of decreasing plumage darkness. Monotypic.

**Distribution.** E of Andes from S Colombia (Putumayo), Ecuador, Peru and SW Amazonian Brazil (E to lower R Juruá and upper R Madeira) S to NW Bolivia (Pando, La Paz).

**Descriptive notes.** 13.5-14.5 cm; 15-17 g. Male is blackish to dark grey (darkest in N); interscapular patch and hidden patch under scapulars white; flight-feathers edged grey, wing-coverts tipped white. Female has crown, upperparts, wings and tail dark grey, tinged olive-grey to olive, interscapular patch white, wing-coverts and flight-feather edges tinged yellowish-brown, underparts reddish-brown to reddish yellow-brown, especially on breast; darkest in N. Subadult male is

like female, moults patchily into adult male plumage. Voice. Male loudsong a series of 4-7 countable (e.g. 4 notes, 1-5 seconds) sharp notes rising in pitch and accelerating slightly; female similar but lower-pitched and often followed by 2-4 soft abrupt notes, usually given in duet at end of male loudsong. Calls include a short to moderately long (e.g. 2 seconds) series of harsh "chak" notes delivered rapidly, and similar notes given in pairs.

**Habitat.** Understorey of humid evergreen-forest borders (*terra firme*, transitional, *várzea*), adjacent tall second growth, and densely vegetated treefalls, light-gaps, lake margins, and

stands of bamboo within forest; lowlands to 1350 m.

**Food and Feeding.** Little published. Feeds on variety of insects, including orthopterans and homopterans (Cicadidae); probably also on spiders. Closely associated partners, individuals, or family groups forage mostly 0-2 m above ground, exceptionally to 7 m; usually alone, seldom with mixed-species flocks. Forages mostly within shaded, dense cover of vine-covered shrubby thickets, treefall tangles and dense bamboo thickets, where difficult to observe; occasionally climbs vines for several metres along larger trunks to forage in clumps of broad-leaved epiphytes. Active but methodical forager, progressing by short hops, separated by pauses of a few seconds to scan for prey; clings laterally to slender vertical stems and vines; posture varies from nearly horizontal to three-quarters upright, with tail usually held level with body or slightly cocked, and often fanned, tail sometimes swung from side to side, wings regularly flicked; movements somewhat erratic, often follows zigzag course with frequent changes of direction. Most prey perch-gleaned from tops and bottoms of live leaves and from stems, vines and branch surfaces, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; probably also sallies to underside of overhanging vegetation in manner of congeners. Rarely follows swarms of army ants (*Eciton burchelli*) as these pass through treefalls or dense second growth (record from Ecuador).

**Breeding.** Nothing known.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon throughout most of its range. Regions occupied by this species include a number of large protected areas, e.g. Yasuni National Park, in Ecuador, Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Serra do Divisor National Park, in Brazil, and Madidi National Park, in Bolivia; also large expanses of intact, suitable habitat that are not formally protected, but seem to be at little risk of being developed in near future. This species' ability to utilize a variety of second-growth habitats renders it less vulnerable to disturbance than are many other antbirds.

**Bibliography.** Alvarez (1994), Alverson *et al.* (2001), Bierregaard *et al.* (1997), Cory & Hellmayr (1924), Fitzpatrick & Willard (1990), Foster *et al.* (1994), Hilty & Brown (1986), Isler & Whitney (2002), Parker & Bailey (1991), Parker & Remsen (1987), Remsen (1986), Ridgely & Greenfield (2001), Ridgely & Tudor (1994), Servat (1996), Sick (1993), da Silva (1992), Stotz *et al.* (1996), Terborgh, Fitzpatrick & Emmons (1984), Terborgh, Robinson *et al.* (1990), Willis (1985a), Zimmer, J.T. (1931a), Zimmer, K.J. (2003a).

## 142. Grey Antbird

### *Cercomacra cinerascens*

**French:** Grisin ardoisé **German:** Aschgrauer Ameisenfänger **Spanish:** Hormiguero Gris  
**Other common names:** Selater's Antbird (*scelateri* and *iterata* combined)

**Taxonomy.** *Formicivora cinerascens* P. L. Selater, 1857, Rio Napo, Ecuador.

Relationships uncertain; thought by some authors to be a sister-species to the "*C. nigricans* species group", or intermediate between the two major *Cercomacra* species groups. Populations fall into two pairs; nominate race and *immaculata* may prove to be a different species from *scelateri* and *iterata*, but differences between races within each pair (especially first of those) may be clinal. Four subspecies recognized.

#### Subspecies and Distribution.

*C. c. cinerascens* (P. L. Selater, 1857) - S Venezuela (W & S Bolivar, Amazonas), SE Colombia, E Ecuador, NE Peru (N of R Amazon and R Marañón) and NW Amazonian Brazil (N Amazonas, Roraima, N Pará W of R Nhamunda).

*C. c. immaculata* Chubb, 1918 - E Venezuela (E Bolivar), the Guianas and NE Amazonian Brazil (Amapá, N Pará E of R Nhamunda).

*C. c. scelateri* Hellmayr, 1905 - E Peru (mainly S of R Amazon and R Marañón but also occurs N of latter), SW Amazonian Brazil (S of R Amazon, E to R Madeira) and NW Bolivia (Pando, La Paz, Beni).

*C. c. iterata* J. T. Zimmer, 1932 - SE Amazonian Brazil (E of R Madeira to W Maranhão, S to Rondônia, W Mato Grosso and S Pará) and NE Bolivia (N Santa Cruz).

**Descriptive notes.** 13-14 cm; 14-18 g. Male nominate race is dark grey above, small white interscapular patch; wings tinged brown, coverts occasionally with minute white spots (often absent); tail blackish-grey, large white terminal spots; underparts medium grey. Female has crown and upperparts olive-brown, interscapular patch almost non-existent, rump greyer, wings darker, wing-coverts with pale yellowish-olive tips, tail slaty with markings as male, throat and underparts olive-yellow, dusky on flanks and crissum. Subadult male is similar to female, but interscapular patch larger; becomes patchily ochraceous and grey

below during moult into adult plumage. Race *immaculata* differs from nominate in interscapular patch absent or minimal, female tail spots smaller; *scelateri* has larger white interscapular patch, wing-coverts with larger white spots at tips, larger white tips on rectrices, male also concealed white patch under anterior scapulars, darker underparts; *iterata* resembles previous but both sexes paler, female rump colour same as mantle, tail olivaceous with black subterminal band. Voice. Male loudsong a short "cuk" followed by long harsh note, or notes in reverse order, or both notes raspy, geographical differences not yet analysed; female loudsong appears to be regular repetition of its call, a short sharp "zhip", sometimes given simultaneously with male loudsong but not in clearly synchronized duet. Calls include slow rattle in which individual notes distinct, fast rattle with notes run together; by male also sharp "k-luck" consisting of abrupt note immedi-

ately followed by longer note; by female also sharp "zhip" (as used in song), and low-pitched nasal growl.

**Habitat.** Vine tangles in subcanopy and mid-storey (including canopy of mid-storey trees) of low-land evergreen forest, mostly below 900 m; occasionally higher, to 1150 m, in Andes.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae, orthopterans, and spiders. Stomach contents from Brazilian specimen included orthopterans (Acrididae), spiders, and at least five species of beetle (Coleoptera). Closely associated pair-members, individuals, or family groups forage mostly 8-20 m above ground, sometimes higher; usually alone, but sometimes joins mixed-species flocks of other insectivores as these pass through its small territory. Foraging behaviour not well known, largely because this species usually remains concealed in tangles high in subcanopy, where exceedingly difficult to observe. Somewhat sluggish in movements, progressing by short hops, with frequent pauses of several seconds to scan for prey; forages mostly in dense vine tangles along major trunks and in interior portions of canopy and subcanopy, hitching from side to side, fanning tail to display spots; also cocks tail to one side and head to other side in display. Perch-gleans most prey from live or suspended dead leaves and from stem, vine and branch surfaces, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; sometimes probes curls of dead leaves with the bill, at other times aggressively tears apart leaves to reach prey hidden inside; also removes caterpillars from silk webs or tents, often by grabbing the larva with the bill and then fluttering down to much lower perch to free it from the silk, returning repeatedly to same web to make multiple captures. Recorded as briefly attending swarms of army ants (*Eciton burchelli*) in Amazonian Brazil.

**Breeding.** Little known. A nest under construction in Sept in French Guiana, c. 10 m off ground in thick clump of lianas, from which nest materials taken; nest in Peru was referred to as being composed principally of leaves and sticks. Eggs from Peru (race *scelateri*) pale brown, streaked and blotched with rich brown and grey; from Guyana (*immaculata*) dull reddish-white, covered all over with dark red-brown and dull brown blotches, streaks and scrawlings.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Common throughout its large range. Range essentially covers most of the humid lowland forest in the Amazon Basin and Guianan region; this includes numbers of protected parks and reserves in virtually every country in which the species occurs, as well as vast areas of suitable habitat which, although not formally protected, are in little danger of development in the short term.

(1932e), Zimmer, K.J. (2003a), Zimmer, K.J. & Hilty (1997).

## 143. Rio de Janeiro Antbird

### *Cercomacra brasiliana*

**French:** Grisin du Brésil **Spanish:** Hormiguero Brasileño  
**German:** Rio de Janeiro-Ameisenfänger

**Taxonomy.** *Cercomacra brasiliana* Hellmayr, 1905, Rio de Janeiro, Brazil.

Relationships uncertain; sometimes considered close to *C. cinerascens* on basis of plumage, but vocalizations suggest a relationship with the "*C. nigricans* group". Monotypic.

**Distribution.** SE Brazil (SE Bahia, E Minas Gerais, Rio de Janeiro and Espírito Santo).

**Descriptive notes.** 13-14 cm. Male is dark grey above, somewhat paler below, white interscapular patch, concealed white patch under anterior scapulars; wings tinged brown, coverts fringed with white at tips; tail graduated, blackish-grey, feathers with narrow white tips. Distinguished from very similar *C. cinerascens* of race *scelateri* by more graduated tail, narrower white tips of rectrices, smaller bill. Female is olive-brown above, broad, diffuse whitish area around eye, interscapular patch almost non-existent, rump greyer, wings darker, tail pale olivaceous brown, throat and underparts bright ochraceous tawny; very narrow buff fringes on tips of wing-coverts and rectrices, presumably soon lost with wear. Voice.

Male loudsong 2-4 rapidly delivered, abrupt, barely audible notes followed by longer (e.g. 0-2 seconds) harsh note; female loudsong abrupt (e.g. 0-06 seconds) notes sounding like "cup", repeated a little irregularly at c. 2 per second; male and female deliver loudsongs simultaneously in imperfectly synchronized duet. Calls include a rapidly delivered series of short notes, first note more emphatic, and frequency-modulated versions of loudsong notes.

**Habitat.** Understorey and mid-storey of dense evergreen second-growth thickets and forest edge, to 950 m. Precise habitat requirements not well understood, but appears capable of adapting to various types of humid, shaded second growth, particularly where vine tangles abundant. In foothills near Boa Nova (Bahia), occupies slopes covered by dense stands of bracken-ferns (*Pteridium*) growing to 2 m or more, with emergent vine-covered shrubs and trees. In same area, found also in more mature second-growth forest along streams, where dense thickets of shrubs and understorey trees are overtopped by interlacing mats of herbaceous vines and bamboo, and where trunks of larger, emergent trees are covered with philodendrons (*Philodendron*) and tangles of hanging vines.

**Food and Feeding.** Almost nothing published. Feeds on variety of insects, including lepidopteran larvae and orthopterans; probably also on spiders. Closely associated partners, individuals, or family groups forage mostly 1-6 m above ground; usually alone, but sometimes briefly joins mixed-species flocks of other insectivores as these pass through its territory. Active but methodical forager, progressing by short hops, with frequent pauses of 1-4 seconds to scan for prey; posture varies from nearly horizontal to three-quarters upright, with tail most often held level with body, sometimes cocked at slight angle and then slowly lowered below horizontal before being flicked upwards again; habitually flicks both wings as it forages. Somewhat erratic in movements, follows zigzag course, often making abrupt changes of direction, frequently retracing routes. Forages mostly in shaded, dense vine tangles, shrubby thickets and dense stands of bracken-fern; sometimes fol-

lows hanging vines up larger tree trunks into slightly more open settings. Perch-gleans most prey from tops and bottoms (in roughly equal proportions) of live leaves and dead bracken, vines, stems and branches, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; frequently makes diagonal to nearly vertical sallies (15–70 cm) to take prey from overhanging vegetation. Often flutter-chases flushed prey with rapid series of wing-assisted hops in which the wings are often fluttered to maintain balance as the bird alternately brakes, accelerates and changes direction within dense tangles; these flutter-chases are directed horizontally and upwards and are a regular part of the species' foraging repertoire, in addition to the more generic sudden downward flutters in pursuit of flushed prey. Also occasionally probes suspended dead leaves, but most dead-leaf foraging is directed at dead fronds of bracken-ferns. Smaller prey immediately swallowed, but larger items bashed repeatedly on branches before consumption; prey capture often accompanied by audible snap of mandibles. Not known to follow army ants.

**Breeding.** Almost nothing known. Territory sometimes apparently no more than 100–150 m in diameter. Eggs light brown, covered almost completely with dark brown spots and flecks, most concentrated in wreath at larger end.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Atlantic Forest Lowlands EBA. Generally rare to uncommon

over whole of its range, but very patchily distributed; locally more common. Skulking habits and reliance on dense thickets of second growth have probably led to its being overlooked in a number of areas where it occurs. In 1996–1997, total of 14 territories located in Serra do Ouricana foothills near Boa Nova, in Bahia, and in a few places 2–3 pairs heard simultaneously; subsequent to 1998, many of the streamside thickets formerly occupied by this species were cleared for planting of bananas, and bracken-covered hillsides supporting multiple territories were completely cleared for planting of coffee; subsequent surveys in 2001–2002 yielded only 2 pairs in the area that previously supported at least 14. More comprehensive survey work is needed in order to locate any additional populations of this species, and to clarify precise habitat requirements. Example from Boa Nova illustrates that it is capable of existing in second-growth habitats at fairly high densities if level of disturbance is not too significant. Should additional "pockets" of local abundance be discovered, steps should be taken to protect as much of the suitable habitat as possible; once such areas have been identified and protected, some habitat management may be required so as to maintain adequate levels of vegetation in the successional stages preferred by the species.

## 144. Rio Branco Antbird

### *Cercomacra carbonaria*

**French:** Grisin charbonnier

**Spanish:** Hormiguero del Branco

**German:** Rio Branco-Ameisenfänger

**Other common names:** Branco Antbird

**Taxonomy.** *Cercomacra carbonaria* P. L. Slater and Salvin, 1873, Rio Branco, Roraima, Brazil. This and *C. nigricans*, *C. melanaria* and *C. ferdinandi* appear to form a species group on basis of plumage, vocalizations and ecology, with *C. manu* probably sister to the group. Monotypic.

**Distribution.** Extreme N Brazil (middle R Branco and tributaries) and adjacent Guyana (R Ireng).

**Descriptive notes.** 14-15.5 cm; one individual 14.5 g. Male is black, outer scapulars edged white, interscapular patch and hidden patch under scapulars white, wing-coverts edged white at tips, inner margins of flight-feathers white; tail graduated, large white tips. Female has crown, head side and upperparts brownish-grey, interscapular patch white, wings and tail dark grey, flight-feathers edged greenish-grey, wing-coverts blackish-grey, tipped white, tail broadly tipped white; throat and upper breast white, spotted dark grey, lower breast and belly streaked grey and buff-white, sides, flanks and crissum buff-grey. **VOICE.** Male

loudsong a couplet consisting of short buzzy note and longer, clearer note, repeated 4-10 (most often 4-7) times; synchronized duet initiated when female interjects loud buzzy note during male loudsong, at which point male shifts to single buzzy note, lower-pitched than female's, and the two notes are alternated antiphonally for 3-5 seconds. Calls include duo or trio of abrupt notes, delivered rapidly, and unclear whine that sounds like a tree branch squeaking in wind.

**Habitat.** Understorey and mid-storey of dense vine thickets bordering lowland tropical river-edge forest. Along banks of R Branco, was found only in dense thickets at edge of gallery forest, within 100 m of river. On nearby river islands apparently more of a habitat generalist, found in dense, relatively young second growth (mostly in overgrown manioc plantations with scattered tall trees), older *Cecropia*-dominated second growth with dense shrubby understorey, and tall (20-30 m canopy), floristically diverse forest with abundant vine tangles.

**Food and Feeding.** Little known. Feeds on insects, including orthopterans (Tettigoniidae), probably also on spiders. Closely associated partners, individuals, or family groups forage mostly 1-7 m above ground, occasionally to 10 m; seems not to follow mixed-species flocks. Active, progresses by short hops, separated by frequent pauses of 0.5-2 seconds to scan for prey; generally traces zigzag route through foliage, with frequent changes of direction; posture between horizontal and 45 degrees, tail frequently wagged up and down in 20-degree arc above and below plane of body, wings flicked constantly. Forages mostly in dense, vine river-edge thickets and regenerating clearings, in leafy crowns of understorey trees, and in central vine tangles near trunks of emergent trees. Perch-gleans most prey from tops and bottoms of live leaves and from vines, stems and branches, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; sometimes makes short (less than 30 cm) fluttering sallies or even shorter jump-gleans to underside of overhanging vegetation; also flutters down abruptly in pursuit of flushed prey.

**Breeding.** Little known. In Roraima, nest found in Aug on São Jose I, and female in heavy moult and with reduced gonads in Oct near Boa Vista, where also many males actively moulting rectrices (and little spontaneous song heard) in Nov; observations suggest that local dry season is non-breeding season. For only known nest, female observed constructing small, delicate cup connected by black rootlets to fork 1.5 m above ground in a main branch in outer, more heavily leaved portion of shrub 3 m tall located in second growth 8 m from edge of manioc field and 50 m from riverbank. Diameter of territories N of Boa Vista appeared to be no more than 100-150 m; territory defended by both members of pair.

**Movements.** Presumed resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species; present in Rio Branco Gallery Forest EBA. Locally fairly common. Occupies tiny range, and does not occur in any formally protected sites. Furthermore, gallery forests and river islands where it is found represent only a fraction of the mapped geographical range; total area potentially occupied by the species has been estimated at 250 km<sup>2</sup> or less. Extrapolation from densities recorded N of Boa Vista yields crude estimate of a maximum mainland population of 3700 birds, with perhaps another 500-1000 on river islands. Main threat may be the burning of habitat; c. 75% of São Jose I was burned in 1998, and widespread fires in Roraima in following year may have had severe impact on river-edge habitats; assessment of impact of these fires is needed. Protection of Boa Agua I and São Jose I (where recorded densities highest) along with areas of gallery forest on adjacent mainland would help to conserve a significant population of this globally threatened species.

**Bibliography.** Bierregaard *et al.* (1997), Collar & Andrew (1988), Collar, Crosby & Stattersfield (1994), Collar, Gonzaga *et al.* (1992), Collar, Wege & Long (1997), Cory & Hellmayr (1924), Dunning (1993), Fitzpatrick & Willard (1990), Isler & Whitney (2002), Ridgely & Tudor (1994), Sick (1993), da Silva (1992), Stattersfield & Capper (2000), Stotz *et al.* (1996), Whittaker (2003b), Zimmer, Whittaker & Stotz (1997).

## 145. Jet Antbird

### *Cercomacra nigricans*

**French:** Grisin de jais

**Spanish:** Hormiguero Azabache

**German:** Nördlicher Trauerameisenfänger

**Taxonomy.** *Cercomacra nigricans* P. L. Slater, 1858, Santa Marta, Magdalena, Colombia.

This and *C. carbonaria*, *C. melanaria* and *C. ferdinandi* appear to form a species group on basis of plumage, vocalizations and ecology, with *C. manu* probably sister to the group. Birds from NW Colombia sometimes separated as race *atrata*, but considered indistinguishable from other populations. Monotypic.

**Distribution.** C & E Panama (from Veraguas on Pacific slope and Colón on Caribbean E to Darién, also Pearl Is), W & N Colombia (Pacific slope in Chocó and Valle, Caribbean slope E to Magdalena, upper Cauca Valley, Magdalena Valley, and base of E Andes S to Meta), W, N & E Venezuela (S

Táchira and W Apure, coastal zone from Aragua E to Delta Amacuro, and along R Orinoco) and W Ecuador.

**Descriptive notes.** 14-15.5 cm; 15-17.5 g (female may weigh less). Male is black, outer scapulars edged white, interscapular patch and hidden patch under scapulars white, wing-coverts edged white at tips, inner margins of flight-feathers white; tail graduated, large white tips. Female is similar to male but blackish-grey, rather than black, whitish eyering, throat narrowly streaked white, sometimes streaks wider and extending down to upper parts of belly, lower belly barred white (differences possibly age-related). Juvenile male is dull brown, tail narrowly tipped white; subadult male is like heavily marked female. **VOICE.** Male loudsong 4

or more pairs of notes, each pair consisting of sharp abrupt note followed by longer buzzy note (e.g. 5 pairs, 2-8 seconds); duet begun when female interjects complex double note into male loudsong, at which point male shifts to single buzzy note, lower-pitched than female's, and the two notes are alternated. Call a harsh note repeated in series at same pace as song or slower, also given singly.

**Habitat.** Understorey and mid-storey of humid, semi-humid and deciduous forest edge and adjacent tall second growth; mainly in lowlands, but to 1400 m in Andes. Found primarily in humid, tangled thickets and dense shrubby borders of both primary forest and tall second growth, particularly where vines abundant, and often near swampy areas. Locally in overgrown plantations adjacent to forest or tall second growth.

**Food and Feeding.** Little published. Feeds on various insects, including lepidopteran larvae, also spiders; stomach contents from Panama included beetles (Coleoptera), bugs (Hemiptera), ants, also unidentified vegetable matter. Closely associated pair-members, individuals, or family groups forage mostly 1-10 m above ground, usually alone, seldom with mixed-species flocks. Forages mostly low within dense vine-covered thickets, or higher within masses of vines along central trunks, where difficult to observe. Active but methodical forager, progressing by short hops, separated by pauses of 1-3 seconds to scan for prey; hitches from side to side up vertical stems and vines and along diagonal limbs; constantly flicks both wings, and tail often wagged slowly down and flicked back up in shallow arc. Perch-gleans most prey from tops and bottoms of live leaves and from stems, vines and branches, by reaching up, out or down with quick stabs of the bill, or by short horizontal lunges; may also make fluttering sallies to foliage, as congeners. Rarely attends army-ant swarms, but two pairs observed disputing for position over a swarm of *Eciton* ants in Panama.

**Breeding.** Little known. In Colombia, adult male feeding juvenile on 10th Mar in Choebó (Quibdó) and juvenile seen in Dec in Meta. Single nest in Colombia (Antioquia) described as made of dry grasses, and placed in fork at extremity of bough of low bush, held 2 eggs, pinkish, heavily spotted and lined with reddish-brown and lilac; additional descriptions from Colombia give eggs as pink, mottled and blotched all over with dark purplish-red and lavender, also with dark irregular lines scattered over shell.

**Movements.** None recorded; presumed resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common throughout its large range, but patchily distributed. Occurs in a number of protected areas, e.g. Soberania and Darién National Parks and Metropolitan Nature Park, in Panama, Tayrona National Park, in Colombia, Guatopo National Park, in Venezuela, and Juaneche Forest Reserve, in Ecuador. This species' ability to exploit a variety of second-growth habitats renders it less vulnerable to disturbance than are many antbirds.

**Bibliography.** Boggs (1961), Cory & Hellmayr (1924), Darlington (1931), Fitzpatrick & Willard (1990), Hallinan (1924), Hilty (2003a), Hilty & Brown (1986), Isler & Whitney (2002), Meyer de Schauensee & Phelps (1978), Morton (1979), Oates & Reid (1903), Parker & Carr (1992), Ridgely & Greenfield (2001), Ridgely & Gwynne (1989), Ridgely & Tudor (1994), Ridgway (1911), Schönwetter & Meise (1967), Slater & Salvin (1879), da Silva (1992), Stotz *et al.* (1996), Wetmore (1972), Willis (1985a), Zimmer (2003a), Zimmer, Whittaker & Stotz (1997).

## 146. Mato Grosso Antbird

### *Cercomacra melanaria*

**French:** Grisin du Mato Grosso

**Spanish:** Hormiguero de Mato Grosso

**German:** Mato Grosso-Ameisenfänger

**Taxonomy.** *Formicivora melanaria* Ménétériés, 1835, Minas Gerais; error = Cuiabá, Mato Grosso, Brazil.

This and *C. carbonaria*, *C. nigricans* and *C. ferdinandi* appear to form a species group on basis of plumage, vocalizations and ecology, with *C. manu* probably sister to the group. Monotypic.

**Distribution.** C & E Bolivia (Beni, Cochabamba, Santa Cruz), extreme N Paraguay (Alto Paraguay) and SC Brazil (S Mato Grosso, W Mato Grosso do Sul).

**Descriptive notes.** 16-16.5 cm; 18.5-19.5 g. Male is black, outer scapulars edged white, interscapular patch and hidden patch under scapulars white, wing-coverts edged white at tips, inner margins of flight-feathers white; tail graduated, large white tips. Differs from *C. nigricans* only in somewhat larger size. Female has head and upperparts olive-grey, interscapular patch white, wings and tail dark grey, wing-coverts tipped white, rectrices tipped white, underparts pale olive-grey, whitest on throat and centre of belly. **VOICE.** Male loudsong 3 buzzy notes, first one abrupt, second long, third intermediate in length, sometimes repeated in short sequences; female nearly identical but higher-pitched; synchronized duet initiated when female interjects loud clearer note during male loudsong, at which point male shifts to similar single clearer note, lower-pitched than female's, the two notes alternated antiphonally for 3-5 seconds. Notes sometimes repeated in doublets, presumably as call.

**Habitat.** Understorey thickets in gallery forest, tropical deciduous forest and seasonally flooded savanna woodland, usually near water, and always with abundance of vines; to 800 m. Particularly

numerous in both gallery forest and swampy woodland hummocks in Pantanal region. Large population was found near Santa Cruz (Bolivia) in a dry forest with numerous floristic elements characteristic of Chaco region; forest was 4-6 m tall, dense, with numerous large columnar cacti (possibly *Cereus dayami*), and abundant cover of terrestrial bromeliads.

**Food and Feeding.** Little published. Feeds on variety of insects and spiders; stomach contents of single Mato Grosso specimen included spiders, orthopterans (Gryllidae), hemipterans (Pentatomidae), and beetles (Chrysomelidae, Galerucinae, Curculionidae). Closely associated partners, individuals, or family groups forage mostly 0-3 m above ground, occasionally to 8 m; mostly alone, but sometimes briefly joining mixed-species flocks of other insectivores as these pass through its territory. Forages mostly in shaded interiors of viny thickets, woody vine tangles in gallery-forest understorey, less frequently at higher levels where masses of vines surround trunks of larger trees; within these microhabitats, forages mostly along open limbs and bare woody vines. Posture varies from nearly horizontal to three-quarters upright, with tail usually in line with plane of body, sometimes slightly cocked, usually held partly fanned and regularly swung from side to side, also slowly wagged downwards c. 30 degrees and then flicked back up to horizontal; frequently flicks both wings as it forages. Active, yet deliberate forager, progresses by short hops and fluttery flights, periodically pausing for 2-5 seconds to scan, at other times making several hops in rapid succession without pausing; somewhat erratic in movements, with frequent changes of direction and retracing of routes. Most prey perched on vine, branch and stem surfaces, by reaching out, up or down with quick stabs of the bill, or by short horizontal lunges; less frequently gleans from live (mostly large) leaves, most often by reaching up to undersides; within thicket interiors, frequently drops to ground to take prey from surface of leaf litter (occasionally probing beneath leaves with the bill), then hops back up to low perches on vines or branches. Not known to follow army ants.

**Breeding.** Little known. Two nests, apparently of this species, found in Dec in Brazil: one made of fine fibres, lined with "horsehair", placed 0.5 m up in fork of branch, 2 eggs being incubated by male; other was in a clearing.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Locally common, particularly in vast areas of Brazilian and Bolivian Pantanal. Only part of Pantanal is formally protected, but nature of seasonal flooding cycles in region provides some natural buffer to human disturbance. A number of proposed hydro-electric schemes, if instituted, could pose significant threat to the general ecosystem of the Brazilian Pantanal.

## 147. Manu Antbird

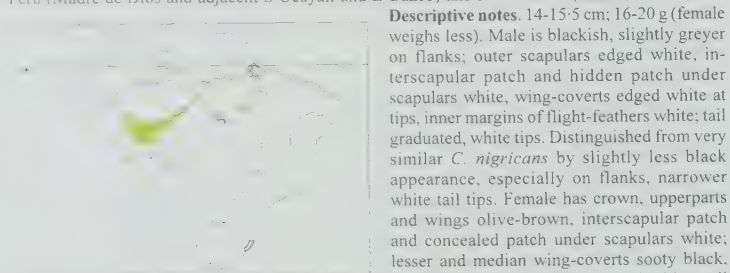

### *Cercomacra manu*

French: Grisin du Manu German: Manuameisenfänger Spanish: Hormiguero del Manu

**Taxonomy.** *Cercomacra manu* Fitzpatrick and Willard, 1990, Shintuya, Madre de Dios, Peru.

Probably a sister-species to the proposed "*C. nigricans* group". Vocalizations possibly vary geographically; analysis of populations needed in order to determine whether taxonomic revision required. Monotypic.

**Distribution.** Locally in S Amazonian Brazil (Acre, SW Amazonas, N Mato Grosso, S Pará, SE Peru (Madre de Dios and adjacent S Ucayali and E Cuzco) and NW Bolivia (Pando, La Paz).

dark greyish-brown, narrowly tipped white; head side, throat and underparts grey, throat faintly streaked white, flanks tinged olive. **VOICE.** Male loudsong a short buzzy note alternated with longer downslurred note, monotonously at relatively slow pace (e.g. 1 note every 0.4 seconds); synchronized duet in which a lower-pitched croaking note by male followed by higher-pitched doublet (sometimes single shorter buzzy note) by female, typically initiated by either sex interjecting its note into male loudsong, repeated variable number of times. Calls include harsh downslurred note, and staccato series of c. 7 abrupt notes dropping in pitch.

**Habitat.** Mid-storey of extensive stands of *Guadua* bamboo in evergreen lowland and foothill forests, locally in riverine forest with thin patches of bamboo; to 1200 m in Peru. Primarily in nearly pure bamboo stands, often near edges of rivers, in lowlands and bluff tops in foothills, as well as along roads and in other areas extensively cleared and with subsequent regenerated bamboo. In Alta Floresta region of Mato Grosso (Brazil), mostly in essentially pure stands of bamboo with fairly open canopy and sunlit interior, and generally absent from smaller shaded thickets inside tall forest in which bamboo thoroughly intermixed with other vegetation (these being occupied by *Drymophila devillei*). In one study area in SE Peru, all territories were located in upland bamboo; at Cocha Cashu, however, as well as in Brazil (SE Pará), observed also in swamp-forest and viny river-edge forest with only thin, scattered bamboo patches.

**Food and Feeding.** Feeds on insects, including lepidopteran larvae and orthopterans; probably also on spiders. Closely associated partners, individuals, or family groups forage mostly 4-15 m above ground, less frequently down to 2 m; alone, or sometimes briefly joining mixed-species flocks of other insectivores as these pass through its small territory. Forages primarily in arching crowns of bamboo, where interspersed vine tangles combine with bamboo branches and foliage to form canopied mats of vegetation; also in vine tangles and shaded canopies of adjacent overstorey trees; in morning hours more in sunlit crowns, descending to lower heights in middle of day. Active, moves along branches in rapid series of short hops, separated by pauses of 1-3 seconds to scan for prey, before taking several more hops in rapid succession; often hitches from side to side as it moves; posture varies from nearly horizontal to three-quarters upright, wings constantly flicked, tail regularly swung from side to side. Perch-gleans most prey from live bamboo foliage and stems, and from interleafed foliage of vine tangles, by reaching up, out or down with quick stabs of the bill; also frequently hover-gleans and makes short (less than 40 cm) fluttering sallies to underside of over-

hanging vegetation, sometimes momentarily hanging upside-down from foliage before dropping back down; sometimes probes in suspended dead leaves trapped in crowns of bamboo.

**Breeding.** Little known. Nest found in Sept in Peru (Madre de Dios), and male carrying food to possible nest or young in Dec in Brazil (Acre). Single known nest described as a pensive pouch with estimated outer diameter 10 cm, outside depth c. 15 cm, composed of dead bamboo leaves laced with long dry fibres (possibly stripped from dry outer clasping sheaths of bamboo), no green vegetation, rim woven on to slender branchlets near point where they forked, suspended from near rim at 3-5 m among dense foliage in a *Guadua weberbaueri* thicket; male observed building nest, and also incubating. Territory small, estimated at 0.5-1 ha in Bolivia, 0.2-0.5 ha at Alta Floresta (Brazil).

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Appears to be fairly common throughout its range, although patchily distributed. In one study area in SE Peru, density recorded in upland bamboo was 25 territories/100 ha; in Brazil, 5 territorial pairs along 100 m of road cut through large bamboo stand at Alta Floresta (Mato Grosso). Regions in which species occurs contain some large protected areas, e.g. Manu National Park and Biosphere Reserve and Tambopata-Candamo Reserved Zone, in Peru, Madidi National Park, in Bolivia, and Serra do Divisor National Park and Cristalino State Park, in Brazil. Disjunct Brazil population in Mato Grosso and Pará merits detailed vocal and biochemical analysis; in view of both its apparent isolation and the rampant clearance of forest in parts of that region, it should also be monitored for population declines. In Alta Floresta region, stands of bamboo that harboured high densities of the species as recently as 1995 have since been clear-cut for conversion to cattle pastures. More surveys needed in SE Amazonia in order to determine extent and distributional limits of populations E of R Madeira.

**Bibliography.** Aleixo (2003), Bierregaard *et al.* (1997), Fitzpatrick & Willard (1990), Foster *et al.* (1994), Isler, M.L. & Isler (2003a), Isler, P.R. & Whitney (2002), Kratter (1997a, 1998), Parker (2003a), Parker & Bailey (1991), Parker & Rensen (1987), Parker *et al.* (1997), Ridgely & Tudor (1994), Rosenberg (2003), Servat (1996), da Silva (1992), Stotz *et al.* (1996), Terborgh *et al.* (1984), Whitney (1997, 2003a), Whittaker & Oren (1999), Zimmer (2003a), Zimmer, Parker *et al.* (1997), Zimmer, Whittaker & Stotz (1997).

## 148. Bananal Antbird

### *Cercomacra ferdinandi*

French: Grisin de Bananal German: Bananalameisenfänger Spanish: Hormiguero de Bananal

**Taxonomy.** *Cercomacra ferdinandi* Sneath, 1928, Furo de Pedra, Ilha do Bananal, Goiás [= Tocantins], Brazil.

Appears to form a species group with *C. melanaria*, *C. carbonaria* and *C. nigricans* on basis of plumage, vocalizations and ecology, with *C. manu* probably sister to the group. Monotypic.

**Distribution.** Bananal I and right bank of R Javaés, in Tocantins, C Brazil.

**Descriptive notes.** 16 cm; 1 individual 15 g. Male is black, outer scapulars edged white, interscapular patch and hidden patch under scapulars white, wing-coverts edged white at tips, inner margins of flight-feathers white; tail graduated, large white tips. Female is similar to male, but black replaced by grey, throat and breast finely streaked white. **VOICE.** Male loudsong harsh, unmusical, staccato, 2 notes given so rapidly as may sound like a single note, followed by 2-10 abrupt single notes delivered rapidly (e.g. 8 notes, 0.7 seconds), entire set repeated in short sequences; synchronized duet initiated when female gives

slightly higher-pitched doublet at conclusion of male loudsong, at which point male shifts to giving only his doublet, the two doublets then alternated antiphonally.

**Habitat.** Mid-storey vine tangles and associated undergrowth of lowland riverine (gallery) forest and adjacent tall second growth; also recorded along edges of oxbow lake. Apparently absent from at least some of the small streams emptying into the river.

**Food and Feeding.** Almost nothing published. Feeds on variety of insects, including orthopterans (Tettigoniidae, Acrididae) and lepidopteran larvae; probably also on spiders. Closely associated partners, individuals, or family groups forage mostly in vine tangles and other dense vegetation 3-15 m above ground; also regularly descends to ground, especially in extended fluttering pursuit of flushed prey (particularly large orthopterans). Usually apart from mixed-species flocks.

**Breeding.** Almost nothing known. Juvenile closely following and being fed by parents in late Aug.

**Movements.** Presumed resident.

**Status and Conservation.** Not globally threatened. Status poorly known; apparently fairly common within its highly restricted range. Much of area occupied by this species falls within Araguaia National Park (5623km<sup>2</sup>). Very little is known of this thamnophilid, and basic research on its natural history, along with surveys to assess population levels, are urgently needed.

**Bibliography.** Aleixo (2003), Bierregaard *et al.* (1997), Fitzpatrick & Willard (1990), Isler & Whitney (2002), Parker (2003a), Ridgely & Tudor (1994), Sick (1993), da Silva (1992), Stattersfield *et al.* (1998), Stotz *et al.* (1996), Zimmer (2003a), Zimmer, Whittaker & Stotz (1997).

## Genus *PYRIGLENA* Cabanis, 1847

## 149. White-backed Fire-eye

### *Pyriglena leuconota*

French: Alapi à dos blanc German: Schwarzes Feuerauge Spanish: Ojodefuego Dorsiblanco

**Taxonomy.** *Myiothera leuconota* Spix, 1824, Pará, Brazil.

Forms a superspecies with *P. atra* and *P. leucoptera*, and sometimes treated as conspecific. Populations of present species appear to involve more than one species; conversely, some races may represent merely clinal variation in plumage; taxonomic study required. Ten subspecies currently recognized.

**Subspecies and Distribution.**

- P. l. pacifica* Chapman, 1923 - W Ecuador and extreme NW Peru (Tumbes).
